tion Head Specialization in Large Language Models

Yanchen Yin, Dongqi Han, Linghui Li

Jailbreak attacks bypass LLM safety alignment, yet their mechanisms remain poorl
y understood. We provide evidence that attacks do not comprehensively eliminate
safety features, but instead selectively suppress specific attention heads. We i
dentify two functionally differentiated types: **Adversarially Compromised Heads
 (ACHs)** concentrated in early layers, which are suppressed under attacks, and
Safety-Aligned Heads (SAHs) in mid-layers, which maintain robust activations
 even when attacks succeed. Ablation studies support the causal role of ACHs and
 the contribution of SAHs to robust activations: suppressing a small number of A
CHs is sufficient to induce jailbreak-like behavior on normally refused inputs,
while removing SAHs substantially weakens mid-layer safety activations. Token-le
vel attribution further shows that ACH suppression is driven specifically by att
ack-template tokens, providing a mechanistic account of why attacks can bypass r
efusal decisions through ACH suppression while leaving internal safety signals s
ustained by SAHs—a phenomenon we term **Robust Harmful Features**. To validate t
he practical significance of this robustness, we show that simply reading these
persistent activations—without any training—yields competitive aggregate detecti
on performance with strong adversarial robustness.

Rubric Curriculum RL: Exploiting the Generation-Verification Gap in Non-Verifiab
le Domains

Tejas Krishnan, Sumeet Ramesh Motwani, Charles London, Suhaas M Bhat, Huitian Ji
ao, Philip Torr, Riashat Islam, Christopher Summerfield, Christian Schroeder de
Witt, Qilong Gu, Shital Shah

Reinforcement learning with verifiable rewards (RLVR) on foundation models has l
ed to significant gains in math and code generation. Extending these gains to op
en-ended domains remains challenging: ground-truth verification is unavailable,
human annotation is expensive, and learned reward models are prone to reward hac

king. We introduce Rubric Curriculum RL (RcRL), a general self-improvement metho d for non-verifiable tasks that requires no new data, human annotations, or stro nger teacher models. RcRL exploits the generation-verification gap, where judgin g good outputs is easier than producing them. We combine pairwise preferences ov er rollouts with a curriculum over rubric criteria, yielding a more discriminati ve signal than absolute scoring while reducing reward hacking through a non-stat ionary objective. Whereas baselines plateau or collapse within a few hundred ste ps, RcRL preserves output entropy and keeps improving past 1000 steps. On creati ve writing, RcRL outputs are preferred 70.5% of the time compared to the base mo del, with consistent gains across multiple creative writing benchmarks and judge s. On HealthBench, RcRL improves over the base model by 14.6% (full set) and 25. 4% (consensus subset), outperforming all HealthBench training baselines, includi ng instance-specific rubrics.

GIFT: Bootstrapping Image-to-CAD Program Synthesis via Geometric Feedback

Giorgio Giannone, Anna C. Doris, Amin Heyrani Nobari, Kai Xu, Akash Srivastava, Faez Ahmed

Generating executable CAD programs from images requires alignment between visual geometry and symbolic program representations, a capability that current method s fail to learn reliably as design complexity increases. Existing fine-tuning ap proaches rely on either limited supervised datasets or expensive post-training p ipelines, resulting in brittle systems that restrict progress in generative CAD design. We argue that the primary bottleneck lies not in model or algorithmic ca pacity, but in the scarcity of diverse training examples that align visual geome try with program syntax. This limitation is especially acute because the collect ion of diverse and verified engineering datasets is both expensive and difficult to scale, constraining the development of robust generative CAD models. We intr oduce Geometric Inference Feedback Tuning (GIFT), a data augmentation framework that leverages geometric feedback to turn test-time compute into a bootstrapped set of high-quality training samples. GIFT combines two mechanisms: Soft-Rejecti on Sampling (GIFT-REJECT), which retains diverse high-fidelity programs beyond e xact ground-truth matches, and Failure-Driven Augmentation (GIFT-FAIL), which co nverts near-miss predictions into synthetic training examples that improve robus tness on challenging geometries. By amortizing inference-time search into the mo del parameters, GIFT captures the benefits of test-time scaling while reducing i nference compute by 80%. It improves mean IoU by 12% over a strong supervised ba seline and remains competitive with more complex multimodal systems, without req uiring additional human annotation or specialized architectures.

A Hypertoroidal Covering for Perfect Color Equivariance

Yulong Yang, Zhikun Xu, Yaojun Li, Christine Allen-Blanchette

When the color distribution of input images changes at inference, the performanc e of conventional neural network architectures drops considerably. A few researc hers have begun to incorporate prior knowledge of color geometry in neural netwo rk design. These color equivariant architectures have modeled hue variation with 2D rotations, and saturation and luminance transformations as 1D translations. While this approach improves neural network robustness to color variations in a number of contexts, we find that approximating saturation and luminance (interva l valued quantities) as 1D translations introduces appreciable artifacts. In thi s paper, we introduce a color equivariant architecture that is truly equivariant . Instead of approximating the interval with the real line, we lift values on th e interval to values on the circle (a double-cover) and build equivariant repres entations there. Our approach resolves the approximation artifacts of previous m ethods, improves interpretability and generalizability, and achieves better pred ictive performance than conventional and equivariant baselines on tasks such as fine-grained classification and medical imaging tasks. Going beyond the context of color, we show that our proposed lifting can also extend to geometric transfo rmations such as scale.

Hölder++: Improving Quality-Coherence Trade-off in Multimodal VAEs

Huyen Thuc Khanh Vo, María Martínez-García, Isabel Valera
Existing approaches for multimodal variational autoencoders (VAEs) face a trade-off between generative quality and coherence—i.e., they struggle to generate realistic and diverse samples that, at the same time, are semantically consistent across modalities. A recent work shows that using a simple approximation to Hölder pooling as an aggregation method improves coherence over the SOTA MMVAE+, despite assuming a single shared representation across all modalities. Yet, it slightly compromises sample diversity. Inspired by this insight, we propose Hölder++, a novel multimodal VAE that improves the generative quality-coherence trade-off through: (i) the first implementation of *Hölder pooling without any approximation* for multimodal VAEs; (ii) an extended architecture that models *distinct shared and private* (i.e., modality-specific) representations (Hölder+); and (iii) *hierarchical inference* that further enhances the disentanglement between the shared and private representations (Hölder++). Our experiments corroborate that Hölder++ consistently improves the generative quality-coherence trade-off, yields more structured latent spaces, and learns shared representations that are informative for downstream tasks.

Query-efficient model evaluation using cached responses
Hayden Helm, Ben Johnson, Carey Priebe
Evaluating a new model on an existing benchmark is often necessary to understand its behavior before deployment.
For modern evaluation frameworks, generating and evaluating a response for all queries can be prohibitively expensive.
In practice, responses from previously-evaluated models are often cached -- creating a potential opportunity to use this additional information to decrease the number of queries required to accurately evaluate a new model.
In this paper, we introduce an approach for predicting benchmark performance that leverages cached model responses based on the Data Kernel Perspective Space (DKPS), a method for quantifying the relationship between models in the black-box setting.
Theoretically, we show that DKPS-based methods are query-efficient under certain conditions.
Empirically, we demonstrate that DKPS-based methods achieve the same mean absolute error as baselines with a substantially decreased query budget.
We conclude by proposing an offline method for selecting a set of queries that maximizes the goodness-of-fit on reference models, improving prediction accuracy over random query selection.

InfoGlobe: Local-and-Global Information-Preserving Statistical Manifold Learning for Single-Cell Transcriptomics
Cheng Wang, Jinpu Cai, Chongxiao Mao, Yuxuan Wang, Xinzhu Jiang, Yunhao Qiao, Luqi Yang, Luting Zhou, Qiuyu Lian, Hongyi Xin
Geometry-preserving dimension reduction is critical for single-cell transcriptomics, where low-dimensional distances should reflect biological divergence between cell types along the transcriptomic manifold. Due to inadequate metrics, the global structure is not sufficiently preserved in the low-dimensional manifold in standard dimension reduction regimes. We model RNA counts as Multinomial samples, leveraging their hierarchical closure property: gene-level counts refine functional gene-group counts via nested Multinomial distributions. Extending Chentsov's Theorem, we show that the Fisher-Rao metric on coarse (gene-group) and fine (gene) statistical manifolds is isometric. Following this isometry property, we propose InfoGlobe, an information-preserving statistical manifold learning framework that projects cells from high-dimensional hyperspheres (full transcriptome) to low-dimensional hyperspheres (functional groups) while preserving information geometry. Embeddings on the low-dimensional sphere explicitly represent Multinomial distributions by functional gene groups. Benchmarks demonstrate superior preservation of local-and-global cell-type geodesic distances, automatic and robust gene-group discovery, nuanced cell subtype resolution without manual feature engineering and natural batch effect mitigation without explicit alignments.

****
COLLIE: Guiding Skill Discovery in Semantically Coherent Latent Space
Yao Luan, Ni Mu, Hanfei Ge, Yiqin Yang, Bo XU, Qing-Shan Jia
Unsupervised skill discovery (USD) aims to learn diverse behaviors without reward functions, but often results in task-irrelevant or hazardous behaviors due to uniform exploration. Guided skill discovery (GSD) addresses this issue by incorporating human intent to focus exploration on meaningful regions. However, existing GSD methods typically require training additional guidance models, and rely on pre-defined rules or expert demonstration, which can be ineffective under sparse, online-collected human feedback. To overcome this, we propose COLLIE, a GSD framework that leverages dense unsupervised data to construct a semantically coherent skill latent space. This latent space is well-structured, enabling reliable guidance with sparse online feedback. Moreover, its semantic coherence property enables training-free construction of guidance signals, eliminating the need for additional model training beyond skill learning. Theoretical analysis justifies the effectiveness of our training-free guidance signal, while experiments across diverse state-based and pixel-based tasks show that COLLIE learns diverse, human-aligned skills, avoids hazardous behaviors, and achieves superior downstream performance with minimal human feedback.
****
STABLEVAL: Disagreement-Aware and Stable Evaluation of AI Systems
Akash Bonagiri, Gerard Janno Anderias, Saee Patil, Angelina Lai, Devang Borkar, Gezheng Kang, Ishant Gandhi, Setareh Rafatirad, Houman Homayoun
Human evaluation remains the primary standard for assessing modern AI systems, yet annotator disagreement, bias, and variability make system rankings fragile under standard majority vote aggregation. Majority vote discards annotator reliability and item-level ambiguity, often yielding unstable comparisons across annotator subsets. We introduce STABLEVAL, a disagreement-aware evaluation framework that models latent item correctness and annotator-specific confusion patterns to produce posterior expected item credit and calibrated agent-level scores. Unlike label-denoising approaches such as Dawid--Skene, STABLEVAL is explicitly designed for stable and uncertainty-aware system evaluation rather than hard label recovery. We formalize ranking stability as a first-class evaluation objective and analyze how aggregation methods preserve or distort underlying annotator behavior. Across controlled synthetic experiments and multiple real-world human-annotated benchmarks, majority vote exhibits increasing score error and ranking instability under annotator heterogeneity and adversarial noise, while STABLEVAL yields more stable and statistically grounded system rankings. These results demonstrate that modeling disagreement is essential for robust and reproducible AI evaluation.

Contractive Anchor Resolvent Diffusion for Incomplete Multi-View Clustering
Tongzheng Zhao, Yangyang Wen, Yukai Shi, Xinyan Liang, Feijiang Li, Peng Zhou, Liang Du
Incomplete Multi-View Clustering (IMVC) is affected not only by missing feature values, but also by the degradation of relational structure induced by missing views. Many graph-based approaches either rely on costly data imputation or adopt first-order fusion mechanisms, which can be viewed as shallow low-pass filters with limited spectral selectivity. As a result, they may be insufficient to distinguish latent consensus structure from view-specific structural variations. To address this limitation, we reformulate IMVC from a spectral filtering perspective and propose \textbf{C}ontractive \textbf{A}nchor \textbf{R}esolvent \textbf{D}iffusion (\textbf{CARD}), a scalable framework for structural refinement without explicit view imputation. CARD constructs a unified anchor-induced hypergraph from observed sample--anchor relations and derives a high-order resolvent diffusion operator that acts as a rational spectral filter. This operator enhances the relative response of consensus-dominant modes while attenuating view-specific variations. We further derive a compact implicit solver that couples similarity learning and clustering without materializing dense matrices, and provide a conditional local refinement analysis under spectral-gap and local-stability assumpti

ons. Extensive experiments on eight benchmarks, including large-scale datasets, show that CARD achieves competitive performance while scaling linearly in \(N\) for a fixed anchor budget. The code for our method is publicly available at \url{https://github.com/Whale-Waves/CARD}.
****
Sinkhorn Normalization of Diffusion Kernels
Nathan Kessler, Robin Magnet, Jean Feydy
Smoothing a signal based on local neighborhoods is a core operation in machine learning and geometry processing. On well-structured domains such as vector spaces and manifolds, the Laplace operator derived from differential geometry offers a principled approach to smoothing via heat diffusion, with strong theoretical guarantees. However, constructing such Laplacians requires a carefully defined domain structure, which is not always available. Most practitioners thus rely on simple convolution kernels and message-passing layers, which are biased against the boundaries of the domain.

We bridge this gap by introducing a broad class of smoothing operators, derived from general similarity or adjacency matrices, and demonstrate that they can be normalized into diffusion-like operators that inherit desirable properties from Laplacians. Our approach relies on a symmetric variant of the Sinkhorn algorithm, which rescales positive smoothing operators to match the structural behavior of heat diffusion.

This construction enables Laplacian-like smoothing and processing of irregular data such as point clouds, sparse voxel grids or mixture of Gaussians. We show that the resulting operators not only approximate heat diffusion but also retain spectral information from the Laplacian itself, with applications to shape analysis and matching.
****
Conditional Clifford-Steerable CNNs for PDE Modeling
Bálint László Szarvas, Maksim Zhdanov
We introduce Conditional Clifford-Steerable CNNs (C-CSCNNs), a unified framework that incorporates equivariance to arbitrary pseudo-Euclidean groups and significantly improves the expressivity of standard CSCNNs. We show that the kernel basis of the standard formulation is incomplete, limiting model capacity. To address this, we augment the kernels with equivariant representations of the input feature field. We derive the equivariance constraint for these input-dependent kernels and show how it can be solved efficiently via implicit parameterization. We empirically validate on multiple PDE forecasting tasks, including fluid dynamics and relativistic electrodynamics, where our method consistently outperforms standard CSCNNs and performs on par with state-of-the-art baselines.
****
Mitigating Manifold Departure: Uncertainty-Aware Subspace Rectification for Trustworthy MLLM Decoding
Yingxuan Zhuang, Jingxiao Yang, Miao Pan, Cheng Tan, Yuxiang Cai, Siwei Tan, Chen Zhi, Xuhong Zhang, Jianwei Yin, Jintao Chen
MLLMs frequently hallucinate objects inconsistent with visual inputs. This issue is typically attributed to the over-reliance on language priors, which can override the visual context. Recent training-free decoding strategies address this by penalizing language priors. However, these methods overlook the dual nature of language priors, where they can be both helpful and harmful depending on the alignment with visual evidence. In particular, blindly suppressing language priors often disrupts the model’s semantic manifold, leading to performance degradation, a phenomenon we term Manifold Departure. To address this, we propose Manifold-Guided Adaptive Projection (MGAP), a geometry-aware, training-free decoding method that mitigates hallucinations while preserving representation structure. MGAP first constructs a language-prior subspace from blind hidden states via SVD. During decoding, MGAP projects each multimodal hidden state onto this subspace and applies a consistency-aware gate to adaptively attenuate only the projected prior component, yielding a subspace-selective update that largely preserves the

orthogonal semantic components. Extensive experiments on POPE and CHAIR show tha t MGAP outperforms prior decoding baselines, achieving stronger hallucination su ppression without sacrificing coherence.

Mitigating Hallucinations in Large Vision-Language Models via Causal Route Gatin g

Zhe Cheng, Wenyu Chen, Fode Zhang, Dehuan Shen

Large vision-language models (LVLMs) often hallucinate content that is fluent ye t unsupported by the image, limiting their reliability in real-world deployment. We show that a key failure mode arises from route competition: even when visual tokens receive attention, the final token decision can be dominated by the text ual pathway, causing the decoder to follow linguistic priors over visual evidenc e. To mitigate this, we propose a training-free, decision-aligned intervention t hat decomposes each attention head into a visual route and a text route, and est imates their token-level effects using an efficient one-forward/one-gradient app roximation. These estimates reveal route conflict within heads and identify prio r-dominant ones, enabling selective suppression of only the text route while kee ping the visual route intact. Across five benchmarks spanning discriminative and generative settings, our method consistently reduces hallucination-related erro rs across models with limited impact on overall multimodal performance, while in curring a modest inference-time overhead.

Parameter Decorrelation via Transition-Variance Alignment for Multivariate Time-series Forecasting

Ji-Eun Choi, Jae-Hong Lee, Joon-Hyuk Chang

Multivariate time-series forecasting (MTSF) learns from high-dimensional covaria tes with strong temporal dependence, periodic structure, and cross-variable corr elations. While modern pipelines often mitigate non-stationarity through instanc e-wise normalization and decomposition, these interventions operate at the data level and do not directly control dependence that can emerge among the parameter s during training. We study MTSF optimization from a parameter-decorrelation vie wpoint. Modeling stochastic optimization as a Markov chain in parameter space an d leveraging its stochastic differential equation interpretation, we use the per -step transition-variance induced by gradient noise as a tractable signal for op timization-induced dependence and update uncertainty. This signal can empiricall y inflate during training; we theoretically show that such inflation can degrade generalization diagnostics. Motivated by this mechanism, we propose transition-variance alignment (TVA), an architecture-agnostic procedure that regulates tran sition-variance by smoothly gating the step size based on the mismatch between a n estimated noise scale and a chosen target. TVA maintains effective transition-variance near a prescribed scale without architectural changes, incurs negligibl e overhead, and integrates seamlessly with diverse methods. Across real-world mu ltivariate benchmarks, TVA consistently improves forecasting accuracy.

Design Linear Constrained Neural Layers with Implicit Convex Optimization

Junchi Yan, Jiaxi Liu, Yihui Tu, Fangyuan Zhou, Wenzheng Pan, Zhongteng Gui, Lia ngliang Shi

One essential limitation of neural networks is how to enforce (hard) constraints on prediction. We propose a plug-in, differentiable layer, which involves a fas t implicit (convex) optimization procedure to enforce the general linear constra int. It aims to minimize a divergence between unconstrained and constrained outp uts. Connecting to and beyond existing handcrafted layers, we show that our laye r degrades to classic layers like Softmax, Sinkhorn and tanh etc. when the corre sponding constraint is enforced by KL-divergence minimization. We further show t hat by replacing the KL-div with a Euclidean distance, a closed-form solution ca n be derived for highly-efficient constraint enforcing. We evaluate the above tw o variants of layers, termed as BLCLayer and GLCLayer, with their corresponding neural solver BLCNet and GLCNet with simple MLP/GNN-like backbone. Experiments o n linear programming, as well as two real-world problems: partial graph matching and portfolio allocation which involve other discrete constraints.

HONet: Data-Efficient Learning for Exact Cover Tasks via Hypergraph Optimization
Pengyang Huang, Zirui Zhuang, Haifeng Sun, Qi Qi, Jingyu Wang, Jianxin Liao
Deep learning approaches typically require prohibitive amounts of data to approximate known-constraint Exact Cover tasks, while existing neuro-symbolic methods often face training infeasibility and scalability bottlenecks. To bridge this divide, we propose the Hypergraph Optimization Network (HONet), an end-to-end framework integrating a structure-preserving Deep Residual Hypergraph Encoder with a differentiable fixed-constraint Quadratic Programming layer. By adopting a ``Fixed Polytope'' paradigm guided by the Geometric Consistency Loss, HONet explicitly shapes the objective landscape, encouraging the valid discrete solution to align with the global energy minimum. Empirical results show that HONet rapidly achieves 100\% accuracy on 9×9 Sudoku using limited samples, exhibiting superior data efficiency over baselines while maintaining exceptional robustness in highly sparse regimes and additional tasks.
****
OpenMAG: A Comprehensive Benchmark for Multimodal-Attributed Graph
Chenxi Wan, Xunkai Li, Yilong Zuo, Haokun Deng, Sihan Li, Bowen Fan, Hongchao Qin, Rong-Hua Li, Guoren Wang
Multimodal-Attributed Graph (MAG) learning has achieved remarkable success in modeling complex real-world systems by integrating graph topology with rich attributes from multiple modalities. With the rapid proliferation of novel MAG models capable of handling intricate cross-modal semantics and structural dependencies, establishing a rigorous and unified evaluation standard has become imperative. Although existing benchmarks have facilitated initial progress, they exhibit critical limitations in *domain coverage*, *encoder flexibility*, *model diversity*, and *task scope*, presenting significant challenges to fair evaluation. To bridge this gap, we present OpenMAG, a comprehensive benchmark that integrates 19 datasets across 6 domains and incorporates 16 encoders to support both static and trainable feature encoding. OpenMAG further implements a standardized library of 24 state-of-the-art models and supports 8 downstream tasks, enabling fair comparisons within a unified framework. Through systematic assessment of necessity, data quality, effectiveness, robustness, and efficiency, we derive 14 fundamental insights into MAG learning to guide future advancements. Our code is available at https://github.com/YUKI-N810/OpenMAG.

Latent Forcing: Reordering the Diffusion Trajectory for Pixel-Space Image Generation
Alan Baade, Eric Ryan Chan, Kyle Sargent, Changan Chen, Justin Johnson, Ehsan Adeli, Li Fei-Fei
Latent diffusion models excel at generating high-quality images but lose the benefits of end-to-end modeling. They discard information during image encoding, require a separately trained decoder, and model an auxiliary distribution to the raw data. In this paper, we propose Latent Forcing, a simple modification to existing architectures that achieves the efficiency of latent diffusion while operating on raw natural images. Our approach orders the denoising trajectory by jointly processing latents and pixels with separately tuned noise schedules. This allows the latents to act as a scratchpad for intermediate computation before high-frequency pixel features are generated. We find that the order of conditioning signals is critical, and we analyze this to explain differences between REPA distillation in the tokenizer and the diffusion model, as well as conditional and unconditional generation. Applied to pixel-space diffusion on ImageNet, Latent Forcing achieves a new state of the art for diffusion transformer-based pixel generation at our compute scale. Code and checkpoints at https://github.com/AlanBaade/LatentForcing

Function-Valued Causal Influence in Nonlinear Time Series
Valentina V. Kuskova, Dmitry Zaytsev, Michael Coppedge
Causal discovery in time series is increasingly performed using nonlinear machine-learning models, yet the resulting causal relationships are almost always summ

arized by scalar edge scores. We argue that this practice obscures the true object learned by nonlinear autoregressive models: a state-dependent function whose effect varies across regimes, magnitudes, and contexts. We formalize function-valued causal influence for additive, contribution-decomposable architectures and show that scalar causal scores constitute a severe information bottleneck, conflating between-state variation with within-state residual noise. Using Neural Additive Vector Autoregression as a representative architecture, we introduce a practical framework based on Individual Conditional Expectation for estimating causal response functions directly from trained models. Through controlled synthetic experiments, we demonstrate that edges with indistinguishable scalar scores can exhibit qualitatively different functional behaviors, including monotonic, thresholded, saturating, and sign-changing effects. An applied case study on democratic development further shows that function-valued analysis reveals regime-specific and asymmetric causal structure systematically missed by score-centric approaches.

Focus and Dilution: The Multi-stage Learning Process of Attention

Zheng-An Chen, Pengxiao Lin, Zhi-Qin John Xu, Tao Luo

Transformer-based models have achieved remarkable success across a wide range of domains, yet our understanding of their training dynamics remains limited. In this work, we identify a recurrent focus–dilution cycle in attention learning and provide a rigorous explanation in a one-layer Transformer setting for Markovian data via gradient-flow analysis. Using stage-wise linearization around critical points, we show that a single focus–dilution cycle can be decomposed into a sequence of distinct stages. First, embedding and projection rapidly condense to a rank-one structure, while attention parameters remain effectively frozen. Then, the attention parameters begin to increase, inducing a frequency-driven focus toward high-frequency tokens. As attention continues to evolve, it generates next-order perturbations in embeddings, leading to a mass-redistribution mechanism that progressively dilutes this focus. Finally, small asymmetries among low-frequency tokens lift a degenerate critical point, opening new embedding directions and initiating the next cycle. Experiments on synthetic Markovian data as well as WikiText and TinyStories corroborate the predicted stages and cyclical dynamics.

****

Autoregression with Self-Token Prediction

Dengsheng Chen, Yangming Shi, Enhua Wu

Conventional autoregressive models achieve causality through next-token prediction, but suffer from prohibitive latency and typically underperform non-causal alternatives such as masked prediction and diffusion. We propose self-token prediction, which enables predicting a flexible number of tokens per step, and introduce SAR, the first spatially autoregressive image generator built on this paradigm. SAR delivers markedly faster inference speeds and consistently outperforms prior autoregressive baselines, achieving performance on par with state-of-the-art non-causal models. Our findings highlight self-token prediction as a crucial step toward a high-quality autoregressive paradigm for visual generation.

Dynamic Stratified Contrastive Learning with Upstream Augmentation for MILP Branching

Tongkai Lu, Shuai Ma, Chongyang Tao

Mixed Integer Linear Programming (MILP) is a fundamental NP-hard problem that has garnered significant attention from both academia and industry.

The Branch-and-Bound (B&B) algorithm is the dominant approach for solving MILPs, where branching decisions play a critical role and have recently been enhanced by neural methods.

However, these methods still struggle with semantic variation across depths, the scarcity of upstream nodes, and the costly collection of strong branching samples.

To address these issues, we propose SC-MILP, a Dynamic Stratified Contrastive Training Framework for MILP Branching.

Our method groups B&B nodes based on their feature distributions and learns dept

h-aware, fine-grained node representations through dynamic stratified contrastiv
e training.
To address data scarcity and imbalance at upstream nodes, we introduce an upstre
am-augmented MILP derivation procedure that generates both theoretically equival
ent and perturbed instances.
Experiments on both synthetic and real-world MILP benchmarks, including large-sc
ale instances, show that SC-MILP significantly improves branching accuracy, redu
ces solving time, with particularly strong gains at upstream nodes.

VR-Thinker: Boosting Multimodal Reward Models through Think with Image Reasoning
Qunzhong Wang, Jie Liu, Jiajun Liang, Yuanxing Zhang, Yilei Jiang, Yaozhi ZHENG,
 Xintao Wang, Pengfei Wan, Xiangyu Yue, Jiaheng Liu
Recent advancements in multimodal reward models (RMs) have substantially improve
d post-training for visual generative models. However, current RMs face inherent
 limitations: **(1)** visual inputs consume large context budgets, forcing fewer
 frames and causing a loss of details; and **(2)** all visual information is pac
ked into the initial prompt, exacerbating forgetting during chain-of-thought rea
soning. To overcome these issues, we introduce **VR-Thinker**, a thinking-with-i
mage RM equipped with visual reasoning operation and a configurable visual memor
y window. This allows the RM to actively acquire visual evidence, improving reas
oning fidelity and reliability. We activate visual reasoning via a reinforcement
 fine-tuning pipeline: **(i)** **Cold Start** with curated visual chain-of-thoug
ht data to distill basic operation formatting; **(ii)** select samples with corr
ect judgments, then conduct **Rejection sampling Fine-Tuning** on these high-qua
lity traces to further enhance reasoning; and **(iii)** apply **Group Relative P
olicy Optimization** (GRPO) to strengthen reasoning. Our approach delivers state
-of-the-art accuracy among open-source models on video preference benchmarks: a
7B **VR-Thinker** achieves 80.5\% on VideoGen Reward, 82.3\% on GenAI-Bench, and
 75.6\% on MJ-Bench-Video.

Data Difficulty and the Generalization–Extrapolation Tradeoff in LLM Fine-Tuning
Siyuan Liu, Tinghong Chen, Xinghan Li, Yifei Wang, Jingzhao Zhang
Data selection during supervised fine-tuning (SFT) can critically change the beh
avior of large language models (LLMs).
Although existing work has studied the effect of selecting data based on heurist
ics such as perplexity, difficulty, or length, the reported findings are often i
nconsistent or context-dependent. In this work, we systematically study the role
 of data difficulty in fine-tuning from both empirical and theoretical perspecti
ves, and find that there is no universally optimal difficulty level; rather, its
 effectiveness depends on the dataset size. We show that for a fixed data budget
, there exists an optimal data difficulty for SFT, and that this optimal difficu
lty shifts toward harder data as the data budget increases. To explain this phen
omenon, we conduct controlled synthetic experiments that reveal a simple underly
ing mechanism: the interplay between the (in-distribution) generalization gap an
d the extrapolation gap. We further support this mechanism through a theoretical
 analysis using PAC-Bayesian generalization bounds. Overall, our results clarify
 how data size and difficulty jointly affect the trade-off between generalizatio
n and extrapolation in SFT, providing guidance for difficulty-based data selecti
on under certain model and data conditions.

Distribution Alignment for One-Shot Federated Learning via Optimal Transport
Daniele Berardini, Vito Paolo Pastore, Vittorio Murino
One-Shot Federated Learning (OSFL) addresses extreme communication regimes in wh
ich clients interact with the server only once, amplifying the impact of heterog
eneous client data distributions. In particular, the interaction of domain shift
 and label shift across clients induces misaligned feature representations that
cannot be corrected through iterative optimization. Existing OSFL methods rely o
n distillation, server-side generation or ensemble-based aggregation, but assume
 aligned representations or address domain and label shift separately. We introd
uce SLOT-Align (Single-round, Learning-free Optimal Transport Alignment), a geom

etry-aware feature harmonization framework for OSFL. SLOT-Align uses a shared fr
ozen encoder to extract compact feature statistics, constructs a global referenc
e via Bures–Wasserstein barycenters, and aligns local representations using clos
ed-form geodesic optimal transport maps. The method is computationally efficient
 and can be combined with existing OSFL pipelines relying on frozen encoders wit
hout modifying their training procedures. Extensive experiments across multiple
benchmarks, pretrained backbones, and OSFL methods show that SLOT-Align consiste
ntly improves accuracy and robustness under joint domain and label shift.

SWING: Unlocking Implicit Graph Representations for Graph Random Features
Alessandro Manenti, Kumar Avinava Dubey, Arijit Sehanobish, Cesare Alippi, Krzys
ztof Marcin Choromanski
We propose SWING: Space Walks for Implicit Network Graphs, a new class of algori
thms for computations involving Graph Random Features on graphs given by implici
t representations (i-graphs), where edge-weights are defined as bi-variate funct
ions of feature vectors in the corresponding nodes. Those classes of graphs incl
ude several prominent examples, such as: *ϵ-neighborhood* graphs, used
on regular basis in machine learning. Rather than conducting walks on graphs' no
des, those methods rely on walks in continuous spaces, in which those graphs are
 embedded. To accurately and efficiently approximate original combinatorial calc
ulations, SWING applies customized Gumbel-softmax sampling mechanism with linear
ized kernels, obtained via random features coupled with importance sampling tech
niques. This mechanism is of its own interest. SWING relies on the deep connecti
on between implicitly defined graphs and Fourier analysis, presented in this pap
er. SWING is accelerator-friendly and does not require input graph materializati
on. We provide detailed analysis of SWING and complement it with thorough experi
ments on different classes of i-graphs.
****
PETS: A Principled Framework Towards Optimal Trajectory Allocation for Efficient
 Test-Time Self-Consistency
Zhangyi Liu, Huaizhi Qu, Xiaowei Yin, He Sun, Yanjun Han, Tianlong Chen, Zhun De
ng
Test-time scaling can improve model performance by aggregating stochastic reason
ing trajectories. However, achieving sample-efficient test-time self-consistency
 under a limited budget remains an open challenge. We introduce PETS (**P**rinci
pled and **E**fficient **T**est-Time **S**elf-Consistency), which initiates a pr
incipled study of trajectory allocation through an optimization framework. Centr
al to our approach is the *self-consistency rate*}, a new measure defined as agr
eement with the infinite-budget majority vote. This formulation makes sample-eff
icient test-time allocation theoretically grounded and amenable to rigorous anal
ysis. We study both offline and online settings. In the offline regime, where al
l questions are known in advance, we connect trajectory allocation to crowdsourc
ing, a classic and well-developed area, by modeling reasoning traces as workers.
 This perspective allows us to leverage rich existing theory, yielding theoretic
al guarantees and an efficient majority-voting-based allocation algorithm. In th
e online streaming regime, where questions arrive sequentially and allocations m
ust be made on the fly, we propose a novel method inspired by the offline framew
ork. Our approach adapts budgets to question difficulty while preserving strong
theoretical guarantees and computational efficiency. Experiments show that PETS
consistently outperforms uniform allocation. On GPQA, PETS achieves perfect self
-consistency in both settings while reducing the sampling budget by up to $75\\%
$ (offline) and $55\\%$ (online) relative to uniform allocation.

Dynamic Fractal Mamba: A Neural Renormalization Group Flow for Scale-Invariant S
equence Modeling
Shenglei Fang, Xianfang Sun, You Zhou
Sequence models typically operate at a fixed temporal or spatial scale and strug
gle to generalize to substantially longer horizons or higher resolutions without
 retraining. Existing hierarchical architectures expand receptive fields but rel
y on scale-specific parameters and lack mechanisms to enforce consistent dynamic

s across scales. We propose Dynamic Fractal Mamba (DF-Mamba), a recursive state-space model that applies a single shared operator across multiple scales. By sharing parameters across recursion depths and exponentially scaling the effective time step, DF-Mamba achieves an exponentially expanding receptive field while preserving linear computational complexity. A learned content-aware coarse-graining module aggregates representations across scales. Auxiliary reconstruction and cross-scale consistency objectives stabilize recursive training. We evaluate DF-Mamba on long-range time-series forecasting, spatial transcriptomics, and computational pathology. Across all tasks, DF-Mamba consistently outperforms Transformers and flat Mamba baselines while using fewer parameters and maintaining linear-time scalability. Importantly, models trained on short sequences or low-resolution inputs generalize in a zero-shot manner to substantially larger temporal and spatial scales unseen during training. These results demonstrate that recursive parameter sharing provides an effective inductive bias for learning scale-consistent and efficient sequence representations.

Polyphonia: Zero-Shot Timbre Transfer in Polyphonic Music with Acoustic-Informed Attention Calibration

Haowen Li, Tianxiang Li, Yi Yang, Boyu Cao, Qi Liu

The advancement of diffusion-based text-to-music generation has opened new avenues for zero-shot music editing. However, existing methods fail to achieve stem-specific timbre transfer, which requires altering specific stems while strictly preserving the background accompaniment. This limitation severely hinders practical application, since real-world production necessitates precise manipulation of components within dense mixtures. Our key finding is that, while vanilla cross-attention captures semantic features of stems, it lacks the spectral resolution to strictly localize targets in dense mixtures, leading to boundary leakage. To resolve this dilemma, we propose *Polyphonia*, a zero-shot editing framework with Acoustic-Informed Attention Calibration. Rather than relying solely on diffuse semantic attention, Polyphonia leverages a probabilistic acoustic prior to establish coarse boundaries, enabling non-target stems preserved precise semantic synthesis. For evaluation, we propose *PolyEvalPrompts*, a standardized prompt set with 1,170 timbre transfer tasks in polyphonic music. Specifically, *Polyphonia* achieves an increase of 15.5% in target alignment compared to baselines, while maintaining competitive music fidelity and non-target integrity.

Opt-Verifier: Unleashing the Power of LLMs for Optimization Modeling via Dual-Side Verification

Haoyang Liu, Jie Wang, Boxuan Niu, Xiongwei Han, Yian Xu, Mingxuan Ye, Zijie Geng, Fangzhou Zhu, Tao Zhong, Mingxuan Yuan, Jianye HAO

Building mathematical optimization models is critical in operations research (OR), while it requires substantial human expertise.

Recent advancements have utilized large language models (LLMs) to automate this modeling process.

However, existing works often struggle to verify the correctness of the generated optimization models, without checking the rationality of the constraints and variables or the validity of solutions to the generated models.

This hampers the subsequent verification and correction steps, and thus it severely hurts the modeling accuracy.

To address this challenge, we propose a novel LLM-based framework with Dual-side Verification (OptiVer) from both structure and solution perspectives, thereby improving the modeling accuracy.

The structure-side verification ensures that the modeling structure of the generated optimization models aligns with the original problem description, accurately capturing the problem's constraints and requirements.

Meanwhile, the solution-side verification interprets and evaluates the validity of the solutions, confirming that the optimization models are logically and mathematically sound.

Extensive experiments on several popular benchmarks demonstrate that our approach significantly outperforms the state-of-the-art, achieving over 20\% improvemen

t in accuracy.

Toward Calibrated Mixture-of-Experts Under Distribution Shift
Gina Wong, Drew Prinster, Suchi Saria, Rama Chellappa, Anqi Liu
Calibration aligns a model's predictive uncertainty with the frequencies of its empirical outcomes and is important for understanding and trusting reported probabilities. Recent work shows that enforcing calibration at the level of individual predictors can improve ensemble accuracy and calibration, with mixture-of-experts (MoE) models showing strong empirical improvements in particular; however, the conditions under which calibration helps MoE are not well understood. In this work, we study how MoE models behave under distribution shift, focusing on how routing mechanisms interact with expert-level calibration. We show that expert calibration is sufficient to ensure calibration of the overall model under a broad class of distribution shifts in hard-routed models, but is insufficient for calibrating soft-routed models. To address this, we propose an adversarial reweighting that penalizes calibration errors of the routed aggregate under distribution shift, and we demonstrate that it improves the accuracy-calibration tradeoff both on average and on difficult subsets of the data, across model classes, prediction tasks, and distribution shifts.

TaskLoom: Weaving Knowledge Across Tasks in World Models
Qingzhang Zeng, Peixi Peng, Hang Li, Luntong Li, Yonghong Tian
World models have significantly improved the sample efficiency of model-based reinforcement learning (MBRL) by enabling policy learning in imagination, thereby reducing the need for direct interaction with the real environment. However, most existing world model methods are trained independently for each task or perform multi-task learning using offline datasets, failing to fully exploit the latent relationships among tasks in online interactive scenarios. To address this limitation, we propose TaskLoom, a knowledge-sharing world model architecture for online RL. TaskLoom adopts a grouped two-stage training paradigm: first, the tasks are divided into several groups based on the similarity of world model gradients,
and fine-grained knowledge is shared among tasks within each group; second, coarse-grained knowledge is exchanged across groups, enabling hierarchical knowledge transfer and reuse.
Experimental results show that TaskLoom outperforms baseline methods on widely used benchmarks such as Proprio Control, Visual Control and Meta-World, validating the effectiveness of the proposed knowledge-sharing mechanism for both low-dimensional state and high-dimensional visual inputs.

Corruption-Tolerant Asynchronous Q-Learning with Near-Optimal Rates
Sreejeet Maity, Aritra Mitra
We study the problem of learning the optimal policy in a discounted, infinite-horizon reinforcement learning (RL) setting in the presence of adversarially corrupted rewards. To address this problem, we develop a novel robust variant of the Q-learning algorithm and analyze it under the challenging asynchronous sampling model with time-correlated data. Despite corruption, we prove that the finite-time guarantees of our approach match existing bounds, up to an additive term that scales with the fraction of corrupted samples. We also establish an information-theoretic lower bound, revealing that our guarantees are near-optimal. Notably, our algorithm is agnostic to the underlying reward distribution and provides the first finite-time robustness guarantees for asynchronous Q-learning. A key element of our analysis is a refined Azuma-Hoeffding inequality for almost-martingales, which may have broader applicability in the study of RL algorithms.
****
Diffusion Models Are Statistically Optimal for Learning Low-Dimensional Multi-Modal Distributions
Jingda Wu, Changxiao Cai
Score-based diffusion models have demonstrated remarkable empirical success in learning high-dimensional distributions, particularly those exhibiting low-dimens

ional and multi-modal structures. However, theoretical understanding of their st atistical efficiency remains limited. Existing theories typically rely on strong regularity assumptions, such as uniformly bounded densities or globally smooth score functions, which fail to capture such intrinsic structures.
In this work, we study the sample complexity of diffusion models for learning di stributions supported on a union of low-dimensional subspaces. Assuming that the data distribution within each subspace is subgaussian, we show that diffusion m odels require at most the order of $\widetilde{O}(\varepsilon^{-k \vee 2})$ (up to some logarithmic factor) samples to achieve ε sampling error in 1 -Wasserstein distance, where k is the intrinsic dimension.
This near-optimal convergence rate depends only on the intrinsic dimension and s ignificantly improves upon prior theoretical guarantees that suffer from the cur se of dimensionality. Notably, our analysis applies to a broad collection of dis tributions without imposing smoothness, bounded-density, or log-concavity assump tions.
Overall, our results show that diffusion models can statistically adapt to intri nsic low-dimensional structure while naturally accommodating multi-modal data, o ffering a rigorous theoretical justification for their success in complex high-d imensional learning tasks.

From Shortcuts to Reasoning: Robust Post-Training of Theory of Mind with Reinfor cement Learning
Jike Zhong, Yuxiang Lai, Ming Li, Yuheng Li, Wuao Liu, Behzad Dariush, Konstanti nos Psounis, Shao-Yuan Lo
Theory of Mind (ToM) is a must-acquire skill for modern foundation model systems to operate effectively and safely in the real world. Recent works have explored honing ToM via post-training; however, we show that such progress is confounded by a pervasive “shortcut” issue: tasks can reach up to 99% accuracy by simply e xploiting spurious causal correlations, leading to a false sense of ToM. Motivat ed by this, we first develop a framework to systematically examine ToM datasets for shortcuts and provide guidance for future development. We find that question s reducible to pure state tracking, such as “belief,” are especially shortcut-pr one compared to mind questions, such as “intention,” where reasoning beyond trac king is required. Using four shortcut-free datasets across three ToM contexts, w e then comprehensively study whether Reinforcement Fine-Tuning with verifiable r ewards and explicit reasoning chains, called Thinking-RFT, elevates ToM beyond S upervised Fine-Tuning, or SFT. Our key findings are as follows. First, Thinking-RFT effectively improves ToM in all scenarios, with a 6% improvement over SFT, p articularly in complex higher-order reasoning, with a 10% improvement over SFT, and multimodal cases, with a 7% improvement over SFT. It also generalizes notabl y better to unseen domains and higher-order queries while being more robust to c ounterfactuals. Second, ToM benefits specifically from the joint effect of reaso ning and RL: Thinking-RFT outperforms No-Thinking-RFT by 7% on average. Third, R FT works by learning to ground its reasoning on anchor cues, such as keywords an d state changes, that correspond to causal factors. We believe our study is usef ul for developing effective and robust ToM post-training datasets and advancing critical ToM capabilities. Project code is available at: https://github.com/jkz-338/Robust-ToM-RL.git

CurvZO: Adaptive Curvature-Guided Sparse Zeroth-Order Optimization for Efficient LLM Fine-Tuning
Shuo Wang, Ziyu Chen, Ming Tang
Fine-tuning large language models (LLMs) with backpropagation achieves high perf ormance but incurs substantial memory overhead, limiting scalability on resource -constrained hardware. Zeroth-order (ZO) optimization provides a memory-efficien t alternative by relying solely on forward passes, yet it typically suffers from slow or unstable convergence due to high-variance gradient estimates. Sparse ZO updates partially address this issue by perturbing only a subset of parameters, but their effectiveness hinges on selecting informative parameters, which is ch allenging in ZO optimization because each query yields only scalar feedback. We

propose Adaptive Curvature-Guided Sparse Zeroth-Order Optimization (CurvZO), whi
ch tracks curvature signals online from scalar ZO feedback and leverages these s
ignals to construct a parameter-wise sampling distribution for selecting coordin
ates at each update, reducing the variance of the sparse ZO gradient estimator.
Moreover, CurvZO dynamically adapts the perturbation budget to the evolving curv
ature signal distribution, yielding sparse ZO updates that remain both focused a
nd sufficiently exploratory. Extensive experiments on OPT and Llama across diver
se NLP tasks show that CurvZO consistently improves fine-tuning performance and
reduces training time over ZO baselines. It improves accuracy by up to 4.4 point
s and achieves up to a $2\times$ speedup, while preserving memory efficiency.

ECHO: Elastic Speculative Decoding with Sparse Gating for High-Concurrency Scena
rios

Xinyi. Hu, Yuhao Shen, Zhang Baolin, Hengxin Zhang, Jun Dai, Shuang Ge, Chen Lei
, Yue Li, Mingcheng Wan

Speculative Decodin promises to accelerate Large Language Model inference, yet i
ts efficacy often degrades in production-grade scenarios. Existing evaluations t
ypically overlook the compute-bound nature of high-concurrency regimes, where ve
rification compute becomes the dominant bottleneck. Consequently, prior methods
face a dilemma: static trees incur massive verification waste, while dynamic tre
es suffer from cumulative misjudgments and kernel incompatibility.

To bridge this gap, we introduce ECHO, a high concurrency-oriented framework int
egrated into SGLang that reformulates speculative execution as a budgeted schedu
ling problem.

Crucially, ECHO employs sparse confidence gating to manage the batch as a unifie
d super-tree, elastically pivoting budget between depth and width to co-optimize
 the trade-off between reducing global verification steps and maximizing per-ste
p efficiency.

Extensive evaluations across diverse model scales—particularly the industrial-gr
ade Qwen3-235B—demonstrate that ECHO consistently outperforms state-of-the-art b
aselines in both low-load and high-load scenarios, achieving up to 5.35$\times$
walltime speedup and delivering over 20\% relative speedup gain against the stro
ngest baselines.

Less Diverse, Less Safe: The Indirect But Pervasive Risk of Test-Time Scaling in
 Large Language Models

Shahriar Kabir Nahin, Hadi Askari, Muhao Chen, Anshuman Chhabra

Test-Time Scaling (TTS) improves LLM reasoning by exploring multiple candidate r
esponses and then operating over this set to find the best output. A tacit premi
se behind TTS is that sufficiently diverse candidate pools enhance reliability.
In this work, we show that this assumption in TTS introduces a previously unreco
gnized failure mode. When candidate diversity is curtailed, even by a modest amo
unt, TTS becomes much more likely to produce unsafe outputs. We present a refere
nce-guided diversity reduction protocol (RefDiv) that serves as a diagnostic att
ack to stress test TTS pipelines. Through extensive experiments across open-sour
ce models (e.g. Qwen3, Mistral, Llama3.1, Gemma3) and two widely used TTS strate
gies (Monte Carlo Tree Search and Best-of-N), constraining diversity consistentl
y signifies the rate at which TTS produces unsafe results. The effect is often s
tronger than that produced by prompts directly with high adversarial intent scor
es. This observed phenomenon also transfers across TTS strategies and to closed-
source models (e.g. OpenAI o3-mini and Gemini-2.5-Pro), thus indicating that thi
s is a general and extant property of TTS rather than a model-specific artifact.
 Additionally, we find that numerous widely used safety guardrail classifiers (e
.g. Llama-Guard), are unable to flag the adversarial input prompts generated by
RefDiv, demonstrating that existing defenses offer limited protection against th
is diversity-driven failure mode.

The Lie We Tell: Correcting the Euclidean Fallacy in Vision Language Action Poli
cies via Score Matching on Tangent Space

Bing-Cheng Chuang, I-Hsuan Chu, Bor-Jiun Lin, YuanFu Yang, Min Sun, Chun-Yi Lee

Diffusion-based Vision-Language-Action policies achieve remarkable success in robotic manipulation, yet commit a fundamental geometric error we term the **Euclidean Fallacy**: representing SE(3) poses as flat $\mathbb{R}^{12}$ vectors. This approximation induces (1) manifold drift violating SO(3) constraints, (2) broken equivariance under coordinate transformations, and (3) non-geodesic trajectories with excessive kinematic cost. We introduce **Lie Diffuser Actor (LDA)**, a diffusion framework operating intrinsically on SE(3). Our method injects noise through left-invariant SDEs, predicts scores in the tangent space, and retracts samples via the exponential map. This formulation eliminates manifold drift by construction while guaranteeing coordinate-frame equivariance and geodesic optimality. On CALVIN ABC$\rightarrow$D, LDA improves average task length from 3.27 to 3.51 ($+7.3\%$). We further validate our method on real robot and the results show that our methodology outperforms the baseline on majority tasks.
****

Near-Optimal Convergence of Accelerated Gradient Methods under Generalized and (L_0,L_1)-Smoothness
Alexander Tyurin
We study first■order methods for convex optimization problems with functions f satisfying the recently proposed ℓ-smoothness condition $||\nabla^{2}f(x)|| \le \ell\left(||\nabla f(x)||\right),$ which generalizes the L-smoothness and (L_{0},L_{1})-smoothness. While accelerated gradient descent (AGD) is known to reach the optimal complexity $\mathcal{O}(\sqrt{L} R / \sqrt{\varepsilon})$ under L-smoothness, where ε is an error tolerance and R is the distance between a starting and an optimal point, existing extensions to ℓ-smoothness either incur extra dependence on the initial gradient, suffer exponential factors in $L_{1} R$, or require costly auxiliary sub-routines, leaving open whether an AGD■type $\mathcal{O}(\sqrt{\ell(0)} R / \sqrt{\varepsilon})$ rate is possible for small-ε, even in the (L_{0},L_{1})-smoothness case. We resolve this open question. Developing new proof techniques, we achieve $\mathcal{O}(\sqrt{\ell(0)} R / \sqrt{\varepsilon})$ oracle complexity for small-ε and virtually any ℓ. For instance, for (L_{0},L_{1})-smoothness, our bound $\mathcal{O}(\sqrt{L_0} R / \sqrt{\varepsilon})$ is provably optimal in the small-ε regime and removes all non-constant multiplicative factors present in prior accelerated algorithms.

Exploration Hacking: Can LLMs Learn to Resist RL Training?
Eyon Jang, Damon Falck, Joschka Braun, Nathalie Maria Kirch, Achyutha Menon, Perusha Moodley, Scott Emmons, Roland S. Zimmermann, David Lindner
Reinforcement learning (RL) has become essential to the post-training of large language models (LLMs) for reasoning, agentic capabilities and alignment. Successful RL relies on sufficient exploration of diverse actions by the model during training, which creates a potential failure mode: a model could strategically alter its exploration during training to influence the subsequent training outcome. In this paper we study this behavior, called exploration hacking. First, we create model organisms of selective RL resistance by fine-tuning LLMs to follow specific underperformance strategies; these models can successfully resist our RL-based capability elicitation in agentic biosecurity and AI R&D environments while maintaining performance on related tasks. We then use our model organisms to evaluate detection and mitigation strategies, including monitoring, weight noising, and SFT-based elicitation. Finally, we show that current frontier models can exhibit explicit reasoning about suppressing their exploration when provided with sufficient information about their training context, with higher rates when this information is acquired indirectly through the environment. Together, our results suggest exploration hacking is a possible failure mode of RL on sufficiently capable LLMs.
****

VideoFlexTok: Flexible-Length Coarse-to-Fine Video Tokenization
Andrei Atanov, Jesse Allardice, Roman Bachmann, O■uzhan Fatih Kar, R Devon Hjelm, David Griffiths, Peter Fu, Afshin Dehghan, Amir Zamir
Visual tokenizers map high-dimensional raw pixels into a compressed representati

on for downstream modeling. Beyond compression, tokenizers dictate what information is preserved and how it is organized. A _de facto_ standard approach to video tokenization is to represent a video as a spatiotemporal 3D grid of tokens, each capturing local information from the original signal. This requires the downstream model, e.g., a text-to-video model, to learn to predict all low-level details "pixel-by-pixel" irrespective of the video's inherent complexity, leading to high learning complexity.
__We present _VideoFlexTok_, which represents videos with a variable-length sequence of tokens structured in a coarse-to-fine manner__, where the first tokens (emergently) capture information such as semantics and motion, and later tokens add fine-grained details. The generative flow decoder enables realistic video reconstructions from any token count. This representation structure allows adapting the token count to downstream needs and encoding videos longer than the baselines within the same budget.
We evaluate VideoFlexTok on class- and text-to-video generative tasks and show that it yields more efficient training than 3D grid tokens, _achieving comparable generation quality (gFVD and ViCLIP Score) with a 5x smaller model (1.1B vs 5.2B)._
Finally, we show how _VideoFlexTok can enable long video generation without prohibitive computational cost_ by training a text-to-video model on 10-second 81-frame videos with only 672 tokens, 8x fewer than a comparable 3D grid tokenizer.

When Preference Labels Fall Short: Aligning Diffusion Models from Real Data
Weiyan Chen, Weijian Deng, Yao Xiao, Weijie Tu, ZiYi Dong, Ibrahim Radwan, Liang Lin, Pengxu Wei
Preference alignment aims to guide generative models by learning from comparisons between preferred and non-preferred samples. In practice, most existing approaches rely on preference pairs constructed from model-generated images. Such supervision is inherently relative and can be ambiguous when both samples exhibit artifacts or limited visual quality, making it difficult to infer what constitutes a truly desirable output. In this work, we investigate whether real data can serve as an alternative source of supervision for preference alignment. We adopt a data-centric perspective and study a curation strategy that treats real images as reference points and constructs preference signals by contrasting them with generated or perturbed samples, without requiring manually annotated preference pairs. Through empirical analysis, we show that real-data-based supervision provides effective guidance for aligning diffusion models and achieves performance comparable to existing preference-based methods. Our results suggest that real data offers a practical and complementary source of supervision for preference alignment and highlight directions of label-efficient alignment strategies. Code and models are available at https://cwyxx.github.io/RealAlign.

On the Emergence of Implicit Curriculum in RLVR Learning Dynamics
Yu Huang, Zixin Wen, Yuejie Chi, Yuting Wei, Aarti Singh, Yingbin Liang, Yuxin Chen
Reinforcement learning with verifiable rewards (RLVR) has been a main driver of recent breakthroughs in large reasoning models. Yet it remains a mystery how rewards based solely on final outcomes can help overcome the long-horizon barrier to extended reasoning. To understand this, we develop a theory of the training dynamics of RLVR for transformers on compositional reasoning tasks. Our theory shows that mixed-difficulty training naturally induces an **implicit curriculum**: without any explicit schedule, easier problems become learnable first and shape the frontier for harder ones, creating a learning progression from easy to hard during optimization. The effectiveness of this curriculum is governed by the smoothness of the difficulty spectrum. When the spectrum is smooth, training dynamics enter a well-behaved *relay* regime, in which persistent gradient signals on easier problems make slightly harder ones tractable and keep training at the edge of competence. When the spectrum contains abrupt discontinuities, training undergoes grokking-type phase transitions with prolonged plateaus before progress recurs. As a technical contribution, our analysis develops and adapts techniques

from Fourier analysis on finite groups to our setting. We validate the predicted mechanisms empirically via synthetic experiments.
****
R^3DAO: Reactive Recovery and Reconstruction for Long-horizon Data Agent Orchestration
Quanxin Liu, Rui Hao, Ruida Xu, Jianwei Zhong, Changhu Chen, Yijun Mo
End-to-end data science agent workflows involve tightly coupled sub-processes with strong dynamic dependencies, posing a challenging long-horizon orchestration problem. Existing frameworks primarily rely on static, chain-like execution plans, which are prone to error propagation from early stages—often causing reasoning chain collapse and task failure, resulting in fragile inference and poor cost-effectiveness. To address these issues, we propose R^3DAO, a reactive data agent orchestration framework based on feedback-driven topology evolution, aiming to build a dynamic evolutionary closed-loop of "hierarchical exploration, iterative recovery, and empirical convergence." First, we introduce a dynamic hierarchical task network that recursively decomposes global intent into macro-logical anchors and micro-operators, enabling low-cost exploration through dimensionality reduction in the logical space. Second, we establish a reactive topology reconfiguration mechanism that leverages semantic reflection to map execution anomalies into diagnostic signals, replacing costly global resets with localized topological optimization for resilient self-healing. Finally, semantic experience distillation implements a dual-loop accumulation that compresses long-horizon trajectories into structured prior, steering execution efficiency toward the optimal regime. Evaluations on the MLE-bench show that R^3DAO achieves a 77.36\% improvement in success rate over advanced R\&D-Agent while maintaining competitive task scores. Notably, R^3DAO compresses the average execution time by 36$\times$ and limits token consumption to just 104k per task, showcasing superior reliability, efficiency, and cost-effectiveness.

LABO: LLM-Accelerated Bayesian Optimization through Broad Exploration and Selective Experimentation
Zhuo Chen, Xinzhe Yuan, Jianshu Zhang, Jinzong Dong, Ruichen Zhou, Yingchun Niu, Tianhang Zhou, Yu Yang Fredrik Liu, Yuqiang Li, Nanyang Ye, Qinying Gu
The high cost and data scarcity in scientific exploration have motivated the use of large language models (LLMs) as knowledge-driven components in Bayesian optimization (BO). However, existing approaches typically embed LLMs directly into the sampling or surrogate modeling pipeline, without fully leveraging their significantly lower evaluation cost compared to real-world experiments. To address this limitation, we propose LLM-Accelerated Bayesian Optimization (LABO), a framework that combines LLM predictions with experimental observations within a single BO loop. LABO employs a gating mechanism to dynamically balance reliance on LLM predictions versus actual experiments. By leveraging inexpensive LLM evaluations to broadly explore the search space and reserving costly real experiments only for regions with high uncertainty, LABO achieves more sample-efficient optimization. We provide a theoretical analysis with a cumulative regret bound that formalizes this efficiency gain. Empirical results across diverse scientific tasks demonstrate that LABO consistently outperforms existing methods under identical experimental budgets. Our results suggest that LABO offers a practical and theoretically grounded approach for integrating LLMs into scientific discovery workflows.

Why Tree-Style Branching Matters for Thought Advantage Estimation in GRPO
Hongcheng Wang, Yinuo Huang, Sukai Wang, Guanghui Ren, Hao Dong
Group Relative Policy Optimization (GRPO) trains Chain-of-Thought reasoning with verifiable rewards, but estimating thought-level advantages without value functions often suffers from high variance. Although tree-style branching is used in practice to reduce variance, it lacks a theoretical explanation of why it works and whether it is important or potentially necessary. We study thought-level advantage estimation in GRPO from a variance perspective under a minimal tree-style setting where multiple continuations are sampled for each thought. Using the mu

ltivariate delta method, we reveal a sampling-dimension asymmetry. Increasing sa
mpled thoughts (K) leaves a strictly positive estimation-variance floor, where
as increasing continuations per thought (M) drives the leading-order estimatio
n variance to zero at rate $1/M$. This implies that, within the fixed-temperatur
e GRPO-style estimator without value models studied here, accurate thought-level
 advantage estimation cannot be achieved by scaling thought sampling alone, maki
ng continuation-level branching a principled and potentially necessary mechanism
 rather than a heuristic. Experiments further provide empirical evidence for its
 effectiveness and potential necessity, demonstrating improved optimization stab
ility, training efficiency, and final performance not only in math but also acro
ss vision domains and under different model architectures and sizes.

Mind the State: Towards Unified, Context-Aware EEG-to-fMRI Synthesis
Yamin Li, Shiyu Wang, Chang Li, Ange Lou, Haatef Pourmotabbed, Sarah Goodale, Da
rio J. Englot, Daniel Moyer, Roza G Bayrak, Catie Chang
Functional magnetic resonance imaging (fMRI) provides dynamic measurements of hu
man brain activity at high spatial resolution and depth, but its use is constrai
ned by high cost, limited accessibility, and strict acquisition requirements. Sy
nthesizing fMRI data from more accessible, non-invasive modalities such as elect
roencephalography (EEG) offers a promising alternative, enabling inference of de
ep brain dynamics from low-cost scalp recordings in naturalistic settings. Despi
te recent progress, existing EEG-to-fMRI translation methods typically rely on r
egion-specific models and offer limited support for subject-level and dataset-le
vel heterogeneity, restricting their generalizability. We propose UniEFS, a unif
ied EEG-to-fMRI Synthesis model that enables full-brain fMRI reconstruction whil
e accommodating varying demographic and physiological contexts within a single m
odel. Our approach leverages a pretrained fMRI decoder to embed rich spatial pri
ors and introduces condition-aware prompt tokens that encode subject-level and e
xperimental metadata, enabling effective handling of heterogeneous datasets. We
extensively evaluate the model performance on eyes-closed resting-state data and
 demonstrate that it can reliably reconstruct temporally-resolved whole-brain fM
RI activity, with potential to generalize to task-based fMRI and clinical popula
tions in a zero-shot manner. Project page: https://soupeeli.github.io/UniEFS

Flatness-Aware Stochastic Gradient Langevin Dynamics
Stefano Bruno, Youngsik Hwang, JaeHyeon An, Sotirios Sabanis, Dongyoung Lim
Flatness of the loss landscape has been widely studied as an important perspecti
ve for understanding the behavior and generalization of deep learning algorithms
. Motivated by this view, we propose Flatness-Aware Stochastic Gradient Langevin
 Dynamics (fSGLD), a first-order optimization method that biases learning its d
ynamics toward flat basins while retaining the computational and memory efficien
cy of SGD and SGLD. We provide a non-asymptotic theoretical analysis showing tha
t fSGLD converges to a flatness-biased Gibbs distribution under a theoretically
prescribed coupling between the noise scale σ and the inverse temperature
 β, together with explicit excess risk guarantees. We empirically evaluate
 fSGLD across standard optimizer benchmarks, Bayesian image classification, unce
rtainty quantification, and out-of-distribution detection, demonstrating consist
ently strong performance and reliable uncertainty estimates. Additional experime
nts confirm the effectiveness of the theoretically prescribed β–σ c
oupling compared to decoupled choices.

From Weak Cues to Real Identities: Evaluating Inference-Driven De-Anonymization
in LLM Agents
Myeongseob Ko, Jihyun Jeong, Sumiran Singh Thakur, Gyuhak Kim, Ruoxi Jia
Anonymization is often assumed to protect privacy once explicit identifiers are
removed, because re-identification has historically required specialized experti
se, tailored algorithms, and manual corroboration. We show that LLM-based agents
 weaken this barrier: by combining scattered, individually non-identifying cues
with public evidence, they reconstruct real-world identities, sometimes even dur
ing benign tasks. We evaluate this risk across three settings---classical linkag

e incidents, a controlled benchmark (\emph{InferLink}) that varies fingerprint t ype, task framing, and attacker knowledge, and open-ended human--AI interaction traces. In the sparsest regime of the Netflix Prize deanonymization setting, age nts reconstruct 79.2\% of identities, against 56.0\% for a classical matching ba seline; on \emph{InferLink}, they link individuals even without an explicit re-i dentification request, and more often once one is given. In redacted human--AI i nteraction traces, agents further resolve anonymized profiles to specific indivi duals by corroborating contextual cues with public evidence. These findings sugg est that privacy evaluations for agentic systems should measure not only what in formation is accessed or disclosed, but also what identities can be inferred.

ReaForest: Fostering Generative Video Reasoning for Spatial Planning
Kun Ouyang, Yuanxin Liu, Xinhao Li, Linli Yao, Xiangyu Zeng, Haoning Wu, Hao Zho u, Fandong Meng, Jie Zhou, Xu Sun
Verbal logic and visual mental simulation are two essential components of human intelligence. Modern Large Language Models (LLMs) have demonstrated strong verba l reasoning capabilities through textual Chain-of-Thought (CoT) reasoning. In co ntrast, current Video Generation Models (VGMs) struggle with visual reasoning ta sks such as spatial planning. We attribute this limitation to two fundamental ga ps:
(i) VGMs are predominantly trained on general-purpose video corpora
emphasizing perceptual fidelity over visual reasoning, leaving
reasoning abilities underdeveloped;
(ii) most VGMs generate videos in a single pass without
mechanisms to explore alternative reasoning trajectories and to revise intermedi ate errors.
Motivated by these limitations, we introduce **ReaForest**, a framework that fos ters the reasoning capacity of VGMs in spatial planning through both training-ti me activation and inference-time scaling.
ReaForest comprises three key components:
(1) ReaGen-27k, a dataset covering diverse spatial planning tasks that requi re multi-step reasoning, which activates basic reasoning capabilities of VGMs fo r spatial planning;
(2) Reflective Entropy-Aware Test-Time Scaling (ReaTTS),
an inference framework that evolves multiple reasoning
branches while enabling failure recovery;
(3) Hierarchical constraint verification, which provides actionable feedback for ReaTTS based on decomposed constraints.
Extensive experiments demonstrate that ReaForest substantially surpasses advance d textual reasoning models (e.g., Gemini-2.5-Pro) and video generation models (e .g., Sora-2). ReaForest exhibits emergent properties including self-correction, parallel thinking, and scalable reasoning, advancing VGMs toward human-like visu al mental simulation.

Towards Fine-Grained Robustness: Attention-Guided Test-Time Prompt Tuning for Vi sion-Language Models
Jia-Wei Hai, Yijun Wang, Xiu-Shen Wei
Vision-Language Models (VLMs), such as CLIP, have achieved significant zero-shot performance on downstream tasks with various fine-tuning adaptation methods. Ho wever, recent studies have proven that adversarial attacks can significantly deg rade the inference ability of VLMs, posing substantial risks to their practical applications. Prevalent test-time adaptation methods typically rely on multi-vie w augmentation to implement various fine-tuning strategies, which struggle to id entify semantic information and are prone to destroying discriminative regions i n fine-grained scenarios. To address these limitations, we propose Attention-Gui ded Test-Time Prompt Tuning (A-TPT), a semantics-preserving method designed for test-time adaptation. We first refine the gradient attention rollout mechanism t o identify semantically meaningful regions surviving under adversarial attacks. Furthermore, we leverage them to guide the spatially varying augmentation intens ities and multi-view ensemble for prompt tuning and inference. Extensive experim

ents demonstrate that A-TPT outperforms existing test-time adaptation methods on both adversarial and clean data. Codes are available at https://github.com/SEU-VIPGroup/A-TPT.

WS-GRPO: Weakly-Supervised Group-Relative Policy Optimization for Rollout-Efficient Reasoning
Gagan Mundada, Zihan Huang, Rohan Surana, Sheldon Yu, Jennifer Yuntong Zhang, Xintong Li, Tong Yu, Lina Yao, Jingbo Shang, Julian McAuley, Junda Wu
Group Relative Policy Optimization (GRPO) is effective for training language models on complex reasoning.
However, since the objective is defined relative to a group of sampled trajectories,
extended deliberation can create more chances to realize relative gains,
leading to inefficient reasoning and overthinking, and complicating the trade-off between correctness and rollout efficiency. Controlling this behavior is difficult in practice, considering
(i) Length penalties are hard to calibrate because longer rollouts may reflect harder problems that require longer reasoning,
penalizing tokens risks truncating useful reasoning along with redundant continuation;
and (ii) supervision that directly indicates when to continue or stop is typically unavailable beyond final answer correctness.
We propose Weakly Supervised GRPO (WS-GRPO), which improves rollout efficiency by converting terminal rewards into correctness-aware guidance over partial trajectories.
Unlike global length penalties that are hard to calibrate, WS-GRPO trains a preference model from outcome-only correctness to produce prefix-level signals
that indicate when additional continuation is beneficial.
Thus, WS-GRPO supplies outcome-derived continue/stop guidance, reducing redundant deliberation while maintaining accuracy.
We provide theoretical results and empirically show on reasoning benchmarks that WS-GRPO substantially reduces rollout length while remaining competitive with GRPO baselines.

Compact Conformal Subgraphs
Sreenivas Gollapudi, Kostas Kollias, Kamesh Munagala, Aravindan Vijayaraghavan
Conformal prediction provides rigorous, distribution-free uncertainty guarantees, but often yields prohibitively large prediction sets in structured domains such as routing, planning, or sequential recommendation. We introduce graph-based conformal compression, a framework for constructing compact subgraphs that preserve statistical validity while reducing structural complexity. We formulate compression as selecting a smallest subgraph capturing a prescribed fraction of the probability mass, and reduce to a weighted version of densest-k-subgraphs in hypergraphs, in the regime where the subgraph has a large fraction of edges. We design efficient approximation algorithms that achieve constant factor coverage and size trade-offs. Crucially, we prove that our relaxation satisfies a monotonicity property, derived from a connection to parametric minimum cuts, which guarantees the nestedness required for valid conformal calibration. Our results therefore not only highlight an algorithmic regime, distinct from classical densest-k-subgraph hardness settings, where the problem can be approximated efficiently, but also bridge conformal prediction with combinatorial graph compression via monotonicity. We finally validate our algorithmic approach via simulations for trip planning and navigation, and compare to natural baselines.

One-step Optimal Transport via Regularized Distribution Matching Distillation
Denis Rakitin, Ivan Shchekotov, Viacheslav Meshchaninov, Dmitry Vetrov
Unpaired domain translation remains a challenging task due to the need of finding a balance between faithfulness and realism. In this paper, we propose a method called Regularized Distribution Matching Distillation (RDMD) that combines the best properties of Optimal Transport (OT) and diffusion-based domain translation

methods. Instead of the conventional adversarial training, RDMD utilizes diffus
ion-based distribution matching, addressing the common shortcomings of OT method
s and providing a strong initialization for the trained models. RDMD provides ef
ficient one-step inference, explicitly controls the input-output alignment via r
egularization of the transport cost and maintains high faithfulness similar to t
he OT methods. We prove that in theory RDMD approximates the OT map and demonstr
ate its empirical performance on several tasks, including unpaired image-to-imag
e translation in pixel and latent space and unpaired text detoxification. Empiri
cal results show that RDMD achieves a comparable or better faithfulness-realism
trade-off compared to the diffusion and OT baselines.

Test-Time Learning of Causal Structure from Interventional Data
Wei Chen, Rui Ding, Huang Bojun, Yang Zhang, Qiang Fu, Yuxuan Liang, Shi Han, Do
ngmei Zhang
Supervised Causal Learning has shown promise in causal discovery, yet it often s
truggles with generalization across diverse interventional settings, particularl
y when intervention targets are unknown. To address this, we propose TICL (Test-
time Interventional Causal Learning), a novel method that synergizes Test-Time
Training with Joint Causal Inference (JCI). Specifically, we design a self-augme
ntation strategy to generate instance-specific training data at test time, effec
tively avoiding distribution shifts. Furthermore, by integrating JCI, we develop
ed a PC-inspired two-phase supervised learning scheme, which effectively leverag
es self-augmented data while ensuring theoretical identifiability. Extensive exp
eriments on bnlearn benchmarks demonstrate TICL's superiority in multiple aspect
s of causal discovery and intervention target detection.

BroRL: Scaling Reinforcement Learning via Broadened Exploration
Jian Hu, Mingjie Liu, Ximing Lu, Fang Wu, Zaid Harchaoui, Shizhe Diao, Yejin Cho
i, Pavlo Molchanov, Jun Yang, Jan Kautz, Yi Dong
Reinforcement Learning with Verifiable Rewards (RLVR) has emerged as a key ingre
dient for unlocking complex reasoning capabilities in large language models. Rec
ent work ProRL has shown promise in scaling RL by increasing the number of train
ing steps. However, performance plateaus after thousands of steps, with clear di
minishing returns from allocating more computation to additional training.
In this work, we investigate a complementary paradigm for scaling RL: \textbf{Br
oRL}—increasing the number of rollouts per example to hundreds to exhaustively \
textbf{Bro}aden exploration, which yields continuous performance gains beyond th
e saturation point observed in ProRL when scaling the number of training steps.
Our approach is motivated by a mass balance equation analysis allowing us to cha
racterize the rate of change in probability mass for correct and incorrect token
s during the reinforcement process. We show that under a one-step RL assumption,
 sampled rollout tokens contribute to correct-mass expansion, while unsampled to
kens outside rollouts may lead to gains or losses depending on their distributio
n and the net reward balance. Importantly, as the number of rollouts per example
 N increases, the effect of unsampled terms diminishes, making overall correct
-mass expansion more likely.
To validate our theoretical analysis, we conduct simulations under more relaxed
conditions and find that a sufficiently large rollout size N—corresponding to
ample exploration—can increase the probability mass of correct tokens broadly, a
nd in our simulator it increases all correct-token probabilities and eliminates
knowledge shrinkage.
Empirically, BroRL revives models saturated after 3K ProRL training steps and de
monstrates robust, continuous improvement, achieving strong results for the 1.5B
 model across diverse benchmarks.
Notably, under the same training time, BroRL is both more data- and compute-effi
cient: large-N rollouts reduce the number of filtered samples during dynamic s
ampling at the algorithmic level and nearly double generation throughput compare
d to ProRL in our hardware setup; this throughput increase is consistent with sh
ifting generation from a more memory-bound regime toward a more compute-bound on
e.

SIMPC: Learning Self-Induced Mirror-Point Consistency for Unsupervised Point Cloud Denoising
Chengwei Zhang, Xueyi Zhang, Tao Jiang, Xinhao Xu, Wenjie Li, Fubo Zhang, Longyong Chen
In point clouds, noise directly perturbs point coordinates that encode both spatial location and geometry, making one-to-one correspondence construction more challenging than in images.
Existing methods impose statistical mappings across noisy variants via noise or optimal transport, but suffer from correspondence ambiguity.
In this work, we propose Self-Induced Mirror-Point Consistency (SIMPC) to learn deterministic correspondences between points and the underlying surface in an unsupervised manner.
For each noisy point, SIMPC generates a mirror-point on the opposite side of the underlying surface, guided by geometric priors during the denoising process.
By encouraging consistency between the denoising targets of the original point and its mirror counterpart, SIMPC effectively localizes the position of underlying surface.
Extensive experiments on synthetic and real-world datasets demonstrate that SIMPC significantly outperforms state-of-the-art unsupervised methods and surpasses several strong supervised counterparts.

On the Ability of Transformers to Verify Plans
Yash Sarrof, Yupei Du, Katharina Stein, Alexander Koller, Sylvie Thiebaux, Michael Hahn
Transformers have shown inconsistent success in AI planning tasks, and theoretical understanding of when generalization should be expected has been limited. We take important steps towards addressing this gap by analyzing the ability of decoder-only models to verify whether a given plan correctly solves a given planning instance. To analyse the general setting where the number of objects -- and thus the effective input alphabet -- grows at test time, we introduce C*-RASP, an extension of C-RASP designed to establish length generalization guarantees for transformers under the simultaneous growth in sequence length and vocabulary size. Our results identify a large class of classical planning domains for which transformers can provably learn to verify long plans, and structural properties that significantly affects the learnability of length generalizable solutions. Empirical experiments corroborate our theory.

Cert-LAS: Toward Certified Model Ownership Verification for Text-to-Image Diffusion Models via Layer-Adaptive Smoothing
Leyi Qi, Yiming Li, Siyuan Liang, Zhengzhong Tu, Dacheng Tao
Large-scale text-to-image (T2I) diffusion models have enabled unprecedented creative applications, but their unauthorized use has raised serious intellectual property concerns, making model ownership verification (MOV) increasingly critical. We find that existing backdoor-based diffusion watermarking methods often (implicitly) assume a "faithful" verification process, namely, that the verifier can query a suspicious model and obtain the faithful watermark response to complete MOV. However, in practice, adversaries may intentionally or unintentionally damage potential watermark signals, significantly degrading verification reliability. To address this issue, we propose Cert-LAS, the first certified MOV method for T2I models based on layer-adaptive smoothing. In general, Cert-LAS embeds specified watermarks using diffusion classifiers and an LFS-guided layer-adaptive noise, and verifies ownership by examining whether the suspected model exhibits significantly stronger watermark responses compared to unwatermarked references through hypothesis testing. We further prove that, under certain conditions, our Cert-LAS can still achieve reliable verification even in the presence of malicious removal attacks. Extensive experiments validate the effectiveness of Cert-LAS and its resistance to adaptive attacks. Our code is available at https://github.com/Leyi-Qi/Cert-LAS.

Inference-Aware Meta-Alignment of LLMs via Non-Linear GRPO
Shokichi Takakura, Akifumi Wachi, Rei Higuchi, Kohei Miyaguchi, Taiji Suzuki
Aligning large language models (LLMs) to diverse human preferences is fundamenta lly challenging since criteria can often conflict with each other. Inference-tim e alignment methods have recently gained popularity as they allow LLMs to be ali gned to multiple criteria via different alignment algorithms at inference time. However, inference-time alignment is computationally expensive since it often re quires multiple forward passes of the base model. In this work, we propose *infe rence-aware meta-alignment* (IAMA), a novel approach that enables LLMs to be ali gned to multiple criteria with minimal computational overhead at inference time. IAMA trains a base model such that it can be effectively aligned to multiple ta sk optima via different inference-time alignment algorithms. To solve the non-li near optimization problems involved in IAMA, we propose *non-linear GRPO*, which provably converges to the optimal solution in the space of probability measures .

Probing RLVR Training Instability through the Lens of Objective-Level Hacking
Yiming Dong, Kun Fu, Haoyu Li, Xinyuan Zhu, Yurou Liu, Lijing Shao, Jieping Ye, Zheng Wang
Prolonged reinforcement learning with verifiable rewards (RLVR) has been shown t o drive continuous improvements in the reasoning capabilities of large language models, but the training is often prone to instabilities, especially in Mixture- of-Experts (MoE) architectures. Training instability severely undermines model c apability improvement, yet its underlying causes and mechanisms remain poorly un derstood. In this work, we introduce a principled framework for understanding RL VR instability through the lens of *objective-level hacking*. Unlike reward hack ing, which arises from exploitable verifiers, objective-level hacking emerges fr om *token-level credit misalignment* and is manifested as system-level spurious signals in the optimization objective. Grounded in our framework, together with extensive experiments on a 30B MoE model, we trace the origin and formalize the mechanism behind a key pathological training dynamic in MoE models: the abnormal growth of the training-inference discrepancy, a phenomenon widely associated wi th instability but previously lacking a mechanistic explanation. These findings provide a concrete and causal account of the training dynamics underlying instab ilities in MoE models, offering guidance for the design of stable RLVR algorithm s.
****
Combinatorial Sparse PCA Beyond the Spiked Identity Model
Syamantak Kumar, Purnamrita Sarkar, Kevin Tian, Peiyuan Zhang
Sparse PCA is one of the most well-studied problems in high-dimensional statisti cs. In this problem, we are given samples from a distribution with covariance $\ \mathbf{\Sigma}$, whose top eigenvector $\\mathbf{v} \in \\mathbb{R}^d$ is s-s parse. Existing sparse PCA algorithms can be broadly categorized into (1) combin atorial algorithms (e.g., diagonal or elementwise covariance thresholding) and (2) SDP-based algorithms. While combinatorial algorithms are much simpler, they a re typically only analyzed under the spiked identity model (where $\\mathbf{\Sig ma} \propto \\mathbf{I}_d + \gamma \\mathbf{v}\\mathbf{v}^\top$ for some $\gamma > 0$), whereas SDP-based algorithms require no additional assumptions on $\\mat hbf{\Sigma}$. We demonstrate explicit counterexample covariances $\\mathbf{\Sig ma}$ against the success of standard combinatorial algorithms for sparse PCA, wh en moving beyond the spiked identity model.
In light of this discrepancy, we give the first combinatorial method for sparse PCA that provably succeeds for general $\\mathbf{\Sigma}$ using $\\mathsf{poly}(s, \log(d))$ samples and $d^2 \cdot \\mathsf{poly}(s, \log(d))$ time, by providi ng a global convergence guarantee on the truncated power method of Yuan and Zhan g (JMLR, 2013). We provide a natural generalization of our method to recovering k sparse principal components. Finally, we evaluate our method on synthetic an d real-world sparse PCA datasets.

Fully Zero-Shot Image Dehazing

Shuocheng Wang, Ruoxi Zhu, Jiaming Liu, Zhengyang Cao, Kun Wang, Chengkang Huang, Lizhuo Liu, Shichen Peng, Minge Jing, Yibo Fan

Image dehazing, an important image restoration problem, aims to recover clear scene content from images degraded by atmospheric haze. Existing dehazing methods rely on observing the distribution of hazy images during training: supervised approaches typically depend on synthetic datasets, leading to poor generalization in real-world scenarios; unsupervised methods are constrained by the limited diversity of observed haze conditions due to the difficulty of collecting real hazy images, and fail to generalize to unseen haze types. To address these challenges, we propose the first fully zero-shot dehazing framework that is trained without any hazy images. The framework is built upon a set of representations that remain invariant across clean and hazy images to bridge the two domains, which is both theoretically derived and experimentally validated. Consequently, we formulate dehazing as a conditional generative modeling problem and train a diffusion model solely with the invariant representations of the abundant and readily available clean images. During testing, the same representations extracted from hazy images serve as the conditional input to guide the diffusion process toward the clean image distribution. Quantitative analyses verify the effectiveness of the proposed representations, and extensive experiments across various real-world hazy datasets demonstrate our framework’s remarkable generalization ability, significantly outperforming existing methods. Our code will be available after the review process.

FOCUS: Forcing In-Context Object Localization through Visual Support Constraints and Policy Optimization

Mohammed Asad Karim, Vinay Kumar Verma

In-context localization (ICL) seeks to localize a target object specified by a small set of support examples in a query image, operating on the fly without training or parameter updates. Despite rapid advances in vision–language models (VLMs), achieving category-agnostic and visually grounded ICL remains an open problem, even though it is essential for applications such as image editing, personalized visual search, and retrieval. Existing methods are fragile and rely on explicit category supervision, which not only limits applicability in realistic settings with unnamed or instance-specific objects but also introduces category bias that steers predictions toward semantic priors rather than visual evidence. We introduce a two-stage training framework that explicitly optimizes in-context attention between support bounding boxes and query images without category supervision. We further refine localization via reinforcement learning using Group Relative Policy Optimization (GRPO) to directly minimize localization error. This formulation enforces visual correspondence over semantic priors, yielding robust instance-level localization. Empirically, a 7B-parameter model trained with our objectives outperforms models up to 72B parameters, demonstrating that context-aware localization objectives can surpass scaling alone. Comprehensive ablations validate the contribution of each component.

Spectral Bridge Variational Inference: Dynamic LoRA via Bures-Wasserstein Gradient Flows

Yuhang Xi, Yu-Feng Yu, Chuan-Xian Ren, Zhao-Rong Lai

Parameter-Efficient Fine-Tuning (PEFT) is essential for adapting Large Language Models, yet existing methods struggle to balance capacity with computational efficiency. Standard approaches enforce rigid low-rank constraints, while dynamic alternatives incur significant memory overheads. To resolve this, we propose Spectral Bridge Variational Inference (SBVI), a geometric framework reformulating LoRA as a continuous Wasserstein gradient flow on the manifold of Gaussian measures. Instead of fixing ranks at initialization, SBVI governs singular value evolution via a stochastic differential equation driven by thermodynamic competition between task gradients and adaptive entropic friction. This induces a spectral bifurcation that automatically prunes noise modes while amplifying signal-rich components, discovering an optimal layer-wise rank distribution. We derive a scalable algorithm with linear complexity using factorized Riemannian retractions and

Empirical Bayes friction updates. Experiments on reasoning and coding benchmarks show SBVI achieves state-of-the-art performance, offering superior accuracy and memory efficiency over existing static and dynamic methods.

Exploring Accurate and Transparent Domain Adaptation in Predictive Healthcare via a Concept-Grounded Orthogonal Inference

Pengfei Hu, Chang Lu, Feifan Liu, Yue Ning

Deep learning models for clinical event prediction on electronic health records (EHR) often suffer performance degradation when deployed under different data distributions.

While domain adaptation (DA) methods can mitigate such shifts, their "black-box" nature prevents widespread adoption in clinical practice where transparency is essential for trust and safety.

We propose ExtraCare to decompose patient representations into invariant and covariant components.

By supervising these two components and enforcing their orthogonality during training, our model preserves label information while exposing domain-specific variation at the same time for more accurate predictions than most feature alignment models.

More importantly, it offers human-understandable explanations by mapping sparse latent dimensions to medical concepts and quantifying their contributions via targeted ablations.

ExtraCare is evaluated on two real-world EHR datasets across multiple domain partition settings, demonstrating superior performance along with enhanced transparency, as evidenced by its accurate predictions and explanations from extensive case studies.

Recovering Hidden Reward in Diffusion-Based Policies

Yanbiao Ji, Qiuchang Li, Yuting Hu, Shaokai Wu, Wenyuan XIE, Guodong ZHANG, Qichen He, Deyi Ji, Yue Ding, Hongtao Lu

This paper introduces EnergyFlow, a framework that unifies generative action modeling with inverse reinforcement learning by parameterizing a scalar energy function whose gradient is the denoising field. We establish that under maximum-entropy optimality, the score function learned via denoising score matching recovers the gradient of the expert's soft Q-function, enabling reward extraction without adversarial training. Formally, we prove that constraining the learned field to be conservative reduces hypothesis complexity and tightens out-of-distribution generalization bounds. We further characterize the identifiability of recovered rewards and bound how score estimation errors propagate to action preferences.

Empirically, EnergyFlow achieves state-of-the-art imitation performance on various manipulation tasks while providing an effective reward signal for downstream reinforcement learning that outperforms both adversarial IRL methods and likelihood-based alternatives. These results show that the structural constraints required for valid reward extraction simultaneously serve as beneficial inductive biases for policy generalization. The code is available at https://github.com/sotaagi/EnergyFlow.

Protein Circuit Tracing via Cross-layer Transcoders

Darin Tsui, Kunal Talreja, Daniel Saeedi, Amirali Aghazadeh

Protein language models (pLMs) have emerged as powerful predictors of protein structure and function. However, the computational circuits underlying their predictions remain poorly understood. Recent mechanistic interpretability methods decompose pLM representations into interpretable features, but they treat each layer independently and thus fail to capture cross-layer computation, limiting their ability to approximate the full model. We introduce ProtoMech, a framework for discovering computational circuits in pLMs using cross-layer transcoders that learn sparse latent representations jointly across layers to capture the model’s full computational circuitry. Applied to the pLM ESM2, ProtoMech recovers 82–89\% of the original performance on protein family classification and function prediction tasks. ProtoMech then identifies compressed circuits that use <1\% of the

latent space while retaining up to 79\% of model accuracy, revealing corresponde nce with structural and functional motifs, including binding, signaling, and sta bility. Steering along these circuits enables high-fitness protein design, surpa ssing baseline methods in more than 70\% of cases. These results establish Proto Mech as a principled framework for protein circuit tracing.

Trustworthy Federated Label Distribution Learning under Annotation Quality Dispa rity

Junxiang Wu, Zhiqiang Kou, Hongwei Zeng, Wenke Huang, Biao Liu, Hanlin Gu, Yuhen g Jia, Di Jiang, Yang Liu, Xin Geng

Label Distribution Learning (LDL) models supervision as an instance-wise probabi lity distribution, enabling fine-grained learning under inherent ambiguity, but its success relies on high-fidelity label distributions that are costly to obtai n and thus often noisy.

Motivated by privacy-sensitive applications, we study Federated Label Distributi on Learning (Fed-LDL), where data isolation further induces heterogeneous annota tion quality across clients, making local updates unevenly reliable and breaking sample-size-based aggregation (e.g., FedAvg).

To address this trust dilemma, we propose FedQual, a quality-aware Fed-LDL frame work with two coupled mechanisms: (i) quality-adaptive client training guided by a global semantic anchor that calibrates low-quality clients while preserving h igh-quality autonomy, and (ii) reliability-aware server aggregation that reweigh ts client contributions by effective reliable information rather than raw sample size.

To enable rigorous evaluation, we construct four new Fed-LDL benchmarks (FER-LDL , FI-LDL, PIPAL-LDL, and KADID-LDL) with controlled annotation quality disparity .

We further provide a theoretical guarantee showing that under heterogeneous supe rvision quality, client-specific calibration is strictly better than any uniform calibration.

Experiments on the proposed benchmarks demonstrate the effectiveness of FedQual.
****

Adaptive Policy Backbone via Shared Network

Bumgeun Park, Donghwan Lee

Reinforcement learning (RL) has achieved impressive results across various domai ns, yet the resulting policies often fail to generalize beyond the specific task s encountered during training. This lack of robustness limits their deployment i n real-world scenarios where diverse and unpredictable task demands exist. In th is work, we provide a theoretical analysis of policy networks under Markov Decis ion Processes (MDPs) and demonstrate that adapting only the linear layers placed before and after a policy backbone is sufficient for task adaptation. Based on this insight, we propose the Adaptive Policy Backbone (APB), which consists of a frozen backbone paired with lightweight, task-specific pre- and post-backbone l inear layers. Our results demonstrate that learning only these lightweight task- specific linear layers is sufficient to achieve performance on par with standard RL, even when the backbone is randomly initialized. Furthermore, we find that t his structural constraint can enhance the generalization capability of the resul ting policies. This advantage extends to out-of-distribution tasks, where repres entative meta-RL baselines often struggle.

DRIVE: Distributional and Retrieval-Augmented Bidding with Value Evaluation

Miduo Cui, Haochen Wang, Shangqin Mao, Xun Yang, Qianlong Xie, Xingxing Wang, Xu ri Ge, Ying Zhou, Zhiwei Xu

Auto-bidding is a core component of real-time advertising systems, where decisio ns must optimize long-term performance under budget and cost constraints, while online exploration is prohibitively risky. Offline reinforcement learning and, m ore recently, Transformer-based sequence modeling have shown promise for learnin g bidding policies from logged data, but their unimodal and purely parametric fo rmulations often collapse multiple effective bidding strategies into suboptimal averaged actions and perform unreliably under sparse or long-tail traffic. To mi

tigate these limitations, we propose **DRIVE** (Distributional and Retrieval-Augmented Bidding with Value Evaluation), a unified Transformer-based framework that decouples candidate action generation from decision making for offline auto-bidding. DRIVE combines distributional action modeling, retrieval-augmented candidate generation from high-quality historical decisions, and value-based evaluation to select the most promising bid at inference time. Extensive experiments on AuctionNet and additional offline reinforcement learning benchmarks demonstrate that DRIVE consistently improves bidding performance and generalizes well across multiple Transformer–based methods.

****

Geometry-Aware Tabular Diffusion

David Turtora Zagardo

Tabular synthesis is critical for privacy-preserving sharing and augmentation, yet diffusion models rely on implicit mechanisms to capture inter-column relationships. We introduce Geometry-Aware Tabular Diffusion (GATD), which augments tabular diffusion denoisers with pairwise angles and lengths computed from column value differences and used as inputs and auxiliary targets. Our MLP instantiation achieves state-of-the-art benchmark performance while using $3.5\times$ fewer parameters on average (up to $25\times$ for classification tasks): on ten datasets, it wins 8/10 Shape, 7/10 Trend, and 9/10 downstream utility (F1/RMSE), reducing Shape and Trend error by 27\% and 20\%. Default loss weights transfer to GNN and Transformer denoisers, improving Shape on 27/30 and Trend on 25/30 architecture-dataset cells. A matched ablation shows supervision (not extra inputs or capacity) drives the gain. This shows explicit relational supervision is a portable inductive bias for tabular diffusion.

$\texttt{FHAIM}$: Fully Homomorphic AIM for Private Tabular Synthetic Data Generation

Mayank Kumar, Qian Lou, Paulo L. Barreto, Martine De Cock, Sikha Pentyala

Data is the lifeblood of AI, yet much of the most valuable data remains locked in silos due to privacy and regulations. As a result, AI remains heavily underutilized in many of the most important domains, including healthcare, education, and finance. Synthetic data generation (SDG), i.e. the generation of artificial datawith a synthesizer trained on real data, offers an appealing solution to make data available while mitigating p rivacy concerns, however existing SDG-as-a-service workflow require data holders to trust providers with access to private data. We propose FHAIM, the first fully homomorphic encryption (FHE) framework for training a marginal-based synthetic data generator on encrypted tabular data. FHAIM adapts the widely used AIM algorithm to the FHE setting using novel FHE protocols, ensuring that the private data remains encrypted throughout and is released only with differential privacy guarantees. Our empirical analysis show that FHAIM preserves the performance of AIM while maintaining feasible runtimes.

Stochastic Linear Bandits with Parameter Noise

Daniel Ezer, Alon Cohen, Yishay Mansour

We study the stochastic linear bandits with parameter noise model, in which the reward of action a is $a^\top \theta$ where θ is sampled i.i.d.

We show a regret upper bound of $\widetilde{O} (\sqrt{d T \log(K/\delta) \sigma^2_{\max}})$ for a horizon T, general action set of size K of dimension d, and where $\sigma^2_{\max}$ is the maximal variance of the reward for any action.

We further provide a lower bound of $\widetilde{\Omega} (d \sqrt{T \sigma_{\max}^2})$ which is tight (up to logarithmic factors) whenever $\log K \approx d$.

For more specific action sets, ℓ_p unit balls with $p \leq 2$ and dual norm q, we show that the minimax regret is $\widetilde{\Theta} (\sqrt{dT \sigma_q^2})$, where σ_q^2 is a variance-dependent quantity that is always at most 4.

This is in contrast to the minimax regret attainable for such sets in the classic additive noise model where the regret is of order $d \sqrt{T}$.

Surprisingly, we show that this optimal (up to logarithmic factors) regret bound

is attainable using a very simple explore-exploit algorithm.
****
Motion-Aware Caching for Efficient Autoregressive Video Generation
Jing Xu, Yuexiao Ma, Xuzhe Zheng, XING WANG, Shiwei Liu, Chenqian Yan, Xiawu Zheng, Rongrong Ji, Fei Chao, Songwei Liu
Autoregressive video generation paradigms offer theoretical promise for long video synthesis, yet their practical deployment is hindered by the computational burden of sequential iterative denoising.
While cache reuse strategies can accelerate generation by skipping redundant denoising steps, existing methods rely on coarse-grained chunk-level skipping that fails to capture fine-grained pixel dynamics.
This oversight is critical: pixels with high motion require more denoising steps to prevent error accumulation, while static pixels tolerate aggressive skipping.
We formalize this insight theoretically by linking cache errors to residual instability, and propose $\textbf{MotionCache}$, a motion-aware cache framework that exploits inter-frame differences as a lightweight proxy for pixel-level motion characteristics.
MotionCache employs a coarse-to-fine strategy: an initial warm-up phase establishes semantic coherence, followed by motion-weighted cache reuse that dynamically adjusts update frequencies per token.
Extensive experiments on state-of-the-art models like SkyReels-V2 and MAGI-1 demonstrate that MotionCache achieves significant speedups of $\textbf{6.28}\times$ and $\textbf{1.64}\times$ respectively, while effectively preserving generation quality (VBench: 1%$\downarrow$ and 0.01%$\downarrow$ respectively).
The code is available at https://github.com/ywlq/MotionCache.
****
Flow Matching Calibration for Simulation-Based Inference under Model Misspecification
Pierre-Louis Ruhlmann, Michael Arbel, Florence Forbes, Pedro L. C. Rodrigues
Simulation-based inference (SBI) is transforming experimental sciences by enabling parameter estimation in complex non-linear models from simulated data. A persistent challenge, however, is model misspecification.
In a Bayesian setting, targeting posterior distributions, errors may arise from the simulator, the noise or prior modelling. These model components are only approximations of reality, and severe mismatches can yield biased or overconfident posteriors. We address this issue by introducing Flow Matching Corrected Posterior Estimation (FMCPE), a framework that leverages the flow matching paradigm to refine simulation-trained posterior estimators using a small set of calibration samples. Our approach proceeds in two stages: first, a posterior approximator is trained on abundant simulated data; second, flow matching transports its predictions toward the true posterior supported by calibration observations.
We rely on the later to guide the correction, without requiring explicit knowledge of the misspecification form or of which model components are affected. This design enables FMCPE to combine the scalability of SBI with robustness to distributional shift. Across synthetic benchmarks and real-world datasets, we show that our proposal consistently mitigates the effects of misspecification, delivering improved inference accuracy and uncertainty quantification compared to standard SBI baselines, while remaining computationally efficient.
****
RA-Det: Towards Universal Detection of AI-Generated Images via Robustness Asymmetry
Xinchang Wang, Yunhao Chen, Yuechen Zhang, Congcong Bian, Zihao Guo, Xingjun Ma, Hui Li
Recent image generators produce photo-realistic content that undermines the reliability of downstream recognition systems. As visual appearance cues become less pronounced, appearance-driven detectors that rely on forensic cues or high-level representations lose stability. This motivates a shift from appearance to behavior, focusing on how images respond to controlled perturbations rather than how they look. In this work, we identify a simple and universal behavioral signal.

Natural images preserve stable semantic representations under small, structured perturbations, whereas generated images exhibit markedly larger feature drift. We refer to this phenomenon as \textbf{robustness asymmetry} and provide a theoretical analysis that establishes a lower bound connecting this asymmetry to memorization tendencies in generative models, explaining its prevalence across architectures. Building on this insight, we introduce Robustness Asymmetry Detection (RA-Det), a behavior-driven detection framework that converts robustness asymmetry into a reliable decision signal. Evaluated across 14 diverse generative models and against more than 10 strong detectors, RA-Det achieves superior performance, improving the average performance by 12.92\%. The method is data- and model-agnostic, requires no generator fingerprints, and transfers across unseen generators. Together, these results indicate that robustness asymmetry is a stable, general cue for synthetic-image detection and that carefully designed probing can turn this cue into a practical, universal detector.

CARD: Coarse-to-fine Autoregressive Modeling with Radix-based Decomposition for Transferable Free Energy Estimation

Ziyang Yu, Yi He, Wenbing Huang, Wen Yan, Yang Liu

Estimating free energy differences quantifies thermodynamic preferences in molecular interactions, which is central to chemistry and drug discovery. Despite fruitful progress, existing methods still face key limitations: classical computational approaches remain prohibitively expensive due to their reliance on extensive molecular dynamics simulations, while deep learning-based methods are constrained by either less-expressive generative models or input dimensions tied to a specific system, resulting in negligible generalization. To address these challenges, we propose CARD, a generative framework that employs a novel radix-based decomposition to bijectively convert 3D coordinates into mixed discrete-continuous sequences, enabling coarse-to-fine autoregressive modeling with enhanced expressiveness. Notably, the model corresponds to a distribution with zero free energy, serving as a proposal for absolute free energy computation of arbitrary systems without relying on alchemical pathways. Experiments across diverse tasks demonstrate that CARD matches the accuracy of classical computational methods on unseen systems with diverse topologies, while achieving an approximately 40-fold speedup in inference.

MVI-Bench: A Comprehensive Benchmark for Evaluating Robustness to Misleading Visual Inputs in LVLMs

Huiyi Chen, Jiawei Peng, Dehai Min, Changchang Sun, Kaijie Chen, Yan Yan, Xu Yang, Lu Cheng

Evaluating the robustness of Large Vision-Language Models (LVLMs) is essential for their continued development and responsible deployment. However, existing robustness benchmarks largely focus on hallucination or misleading textual inputs, overlooking the critical challenge posed by misleading visual inputs in assessing visual understanding. To fill this gap, we introduce MVI-Bench, the first comprehensive benchmark specially designed for evaluating how Misleading Visual Inputs undermine the robustness of LVLMs. Grounded in fundamental visual primitives, the design of MVI-Bench centers on three hierarchical levels of misleading visual inputs: Visual Concept, Visual Attribute, and Visual Relationship. Using this taxonomy, we curate six representative categories and compile 1,248 expertly annotated VQA instances. To facilitate fine-grained robustness evaluation, we further introduce MVI-Sensitivity, a novel metric that characterizes LVLM robustness. Empirical results across 18 state-of-the-art LVLMs uncover pronounced vulnerabilities to misleading visual inputs, and our in-depth analyses on MVI-Bench provide actionable insights that can guide the development of more reliable and robust LVLMs.

Causal Detection of Multi-Step LLM Agent Attacks

Viraaji Mothukuri, Reza M. Parizi

Multi-step prompt injection attacks on LLM agents present a fundamental detection challenge because malicious intent emerges only after the workflow completes,

while individual actions remain legitimate in isolation. Existing defenses, including input sanitization, output validation, and instruction hierarchy, operate on individual actions or content patterns and cannot capture this sequential structure. We present **CausalTrace**, a detection system that reframes prompt-injection defense as causal inference. It constructs Structural Causal Models from agent trajectories with typed edges capturing data dependency, trust transfer, and state enablement, then applies Pearl’s do-calculus to answer a counterfactual question, namely, whether the harmful outcome would have occurred if the injection had been blocked. This formalization enables a principled distinction between attacks that depend on injections and benign workflows that share surface-level features. Evaluation on a dataset spanning crowdsourced traces, LLM agent benchmarks, and semi-real and real scenarios demonstrates strong detection performance, outperforming content-based baselines while requiring minimal LLM inference cost; bidirectional slicing recovers complete attack chains with high edge recall, providing interpretable explanations that trace exploitation to its causal origins.

SFedPO: Streaming Federated Learning with a Prediction Oracle under Temporal Shifts

Jinrui Zhou, Haotian Xu, Xichong zhang, He Sun, Mingjun Xiao

Federated Learning (FL) enables decentralized clients to collaboratively train a global model without sharing raw data. However, most existing FL frameworks assume that clients train on static local datasets collected in advance or that the data follows a fixed underlying distribution, which limits their applicability in dynamic environments where data evolves over time. A parallel line of research, online FL, removes all assumptions and adopts an adversarial perspective, but this approach is often overly pessimistic and neglects the structured, partially predictable nature of real-world data dynamics. To bridge this gap, we propose SFedPO, a streaming federated learning framework that incorporates a prediction oracle to capture the temporal evolution of client-side data distributions. We theoretically analyze the convergence bounds of SFedPO and develop two practical sampling strategies: a Distribution-guided Data Sampling (DDS) strategy that dynamically selects training data under limited storage by balancing historical reuse and distribution adaptation, and a Shift-aware Aggregation Weights (SAW) mechanism that modulates global aggregation based on client-specific sampling behaviors. We further establish robustness guarantees under prediction errors. Extensive experiments demonstrate that SFedPO effectively adapts to streaming scenarios with distribution shifts and significantly outperforms existing methods.

3DGS^2-TR: A Scalable Second-Order Trust-Region Method for 3D Gaussian Splatting

Roger Hsiao, Yuchen Fang, Xiangru Huang, Ruilong Li, Hesam Rabeti, Zan Gojcic, Javad Lavaei, James Demmel, Sophia Shao

We propose 3DGS^2-TR, a second-order optimizer for accelerating the scene training problem in 3D Gaussian Splatting (3DGS). Unlike existing second-order approaches that rely on explicit or dense curvature representations, such as 3DGS-LM (Höllein et al., 2025) or 3DGS2 (Lan et al., 2025),

our method approximates curvature using only the diagonal of the Hessian matrix, estimated efficiently via Hutchinson’s method.

Our approach is fully matrix-free and has the same complexity as ADAM (Kingma, 2024), $O(n)$ in both computation and memory costs.

To ensure stable optimization in the presence of strong nonlinearity in the 3DGS rasterization process, we introduce a parameter-wise trust-region technique based on the squared Hellinger distance, regularizing updates to Gaussian parameters.

Under identical parameter initialization and without densification, 3DGS^2-TR is able to achieve better reconstruction quality on standard datasets, using 50\% fewer training iterations compared to ADAM, while incurring less than 1GB of peak GPU memory overhead (17\% more than ADAM and 85\% less than 3DGS-LM),

enabling scalability to very large scenes and potentially to distributed tra

ining settings.

Student-Centered Distillation Narrows the Agentic Gap Between Small and Large LLMs
Yuanjie Lyu, Chengyu Wang, Jun Huang, Tong Xu
Large Language Model agents achieve strong performance on multi-step reasoning and tool-use tasks, but their impressive capabilities typically rely on extremely large backbones. Existing distillation approaches train smaller students to imitate full teacher trajectories, yet reasoning and knowledge gaps between the teacher and student can cause compounding errors. We propose SCoRe, a student-centered framework in which the student generates training trajectories and the teacher corrects only the earliest error, producing training data matched to the student's abilities and exposing specific weaknesses. The student is first fine-tuned on corrected trajectories. Subsequently, short-horizon reinforcement learning starts from the verified prefix preceding the earliest error, with target rewards assigned at that step. This design enables the student to solve problems through unconstrained RL exploration rather than teacher imitation, while the short-horizon setup improves training stability. On 12 challenging benchmarks, a 7B-parameter student distilled with SCoRe closes the agentic performance gap with a 72B-parameter teacher.
****
Towards Long-Horizon Interpretability: Efficient and Faithful Multi-Token Attribution for Reasoning LLMs
Wenbo Pan, Zhichao Liu, Xianlong Wang, Yu Haining, Xiaohua Jia
Token attribution methods provide intuitive explanations for language model outputs by identifying causally important input tokens. However, as modern LLMs increasingly rely on extended reasoning chains, existing schemes face two critical challenges: (1) efficiency bottleneck, where attributing a target span of M tokens within a context of length N requires $\mathcal{O}(M \cdot N)$ operations, making long-context attribution prohibitively slow; and (2) faithfulness drop, where intermediate reasoning tokens absorb attribution mass, preventing importance from propagating back to the original input. To address these, we introduce FlashTrace, an efficient multi-token attribution method that employs span-wise aggregation to compute attribution over multi-token targets in a single pass, while maintaining faithfulness. Moreover, we design a recursive attribution mechanism that traces importance through intermediate reasoning chains back to source inputs. Extensive experiments on long-context retrieval (RULER) and multi-step reasoning (MATH, MorehopQA) tasks demonstrate that FlashTrace achieves over $130\times$ speedup over existing baselines while maintaining superior faithfulness. We further analyze the dynamics of recursive attribution, showing that even a single recursive hop improves faithfulness by tracing importance through the reasoning chain.
****
MidSteer: Optimal Affine Framework for Steering Generative Models
Tatiana Gaintseva, Andrew Stepanov, Ziquan Liu, Martin Benning, Gregory Slabaugh, Jiankang Deng, Ismail Elezi
Steering intermediate representations has emerged as a powerful strategy for controlling generative models. However, despite its empirical success, it currently lacks a comprehensive theoretical framework. In this paper, we bridge this gap by formalizing the theory of concept steering. First, we establish a link between steering and affine concept erasure, proving that the standard approach for removing unwanted behaviors is a special case of LEACE (a closed-form method for affine erasure). Next, we formulate a principled theoretical framework for concept switching, LEACE-Switch, and characterize the assumptions under which it provides an optimal affine solution. Building on this analysis, we then introduce MidSteer (Minimal Disturbance concept Steering), a more general affine framework for concept manipulation that relaxes these assumptions and enables directed, minimal-disturbance transformations. We empirically demonstrate that MidSteer performs favorably across a range of tasks, modalities, and architectures, including vision diffusion models and large language models.

Functional Attention: From Pairwise Affinities to Functional Correspondences
Jiefang Xiao, Maolin Gao, Simon Weber, Guandao Yang, Daniel Cremers
Learning mappings between infinite-dimensional function spaces, or operator lear
ning, is essential for many machine learning applications.
Although transformer-based operators are popular, they often rely on token-wise
attention.
These methods treat continuous fields as discrete tokens and usually ignore the
global functional structure.
We introduce *Functional Attention*, which reinterprets attention as a functiona
l correspondence between adaptive bases.
Inspired by geometric functional maps, our method replaces softmax affinities wi
th structured linear operators. This yields a compact, generalizable, resolution
-invariant representation that explicitly captures global dependencies.
Experiments demonstrate that *Functional Attention* can match state-of-the-art p
erformance in many operator learning tasks, including solving PDEs, 3D segmentat
ion, and regression, while remaining robust to varying discretizations. Project
page is available at https://github.com/xjffff/FUNCATTN.

Riemannian Metric Matching for Scalable Geometric Modeling of Distributions
Jacob Bamberger, Adam Gosztolai, Pierre Vandergheynst, Michael M. Bronstein, Iol
o Jones
High-dimensional datasets often concentrate near low-dimensional structures, but
 estimating their geometry from samples typically relies on graphs and kernels t
hat scale poorly with dataset size and dimension.
We propose **Riemannian metric matching**: a denoising probabilistic framework f
or learning the Riemannian geometry of data using neural networks.
Specifically, we learn the *carré du champ* operator, which, using diffusion geo
metry, gives us access to the Riemannian geometry toolkit for downstream machine
 learning and statistical tasks.
Our key observation is that the carré du champ operator can be formulated as a c
onditional expectation over random perturbations of the data,
which can be exploited for sample-wise training and constant cost, amortized inf
erence without explicit kernel construction.
Empirically, metric matching rivals or improves the accuracy of k-NN-based dif
fusion geometry estimators, while enabling amortized inference that is up to $40
0\times$ faster, and supports graph-free geometric analysis on high-dimensional
images where nearest neighbors break down.

Decision-focused Sparse Tangent Portfolio Optimization
Haeun Jeon, Seunghoon Choi, Hyunglip Bae, Yongjae Lee, Woo Chang Kim
Sparse tangent portfolio optimization aims to learn an interpretable, low-cardin
ality portfolio in the tangency direction of the mean-variance frontier. However
, the associated cardinality-constrained formulation is NP-hard, and standard pr
edict-then-optimize pipelines often misalign forecasting accuracy with downstrea
m portfolio quality. We propose an end-to-end decision-focused learning framewor
k that reformulates Sharpe ratio maximization as a Disciplined Parametrized Prog
ramming (DPP)-compliant convex programming layer and replaces discrete selection
 with a smooth top-k operator enforcing an exact cardinality k. This enables
 gradient flow through prediction, asset selection, and re-optimization, allowin
g the predictive model to directly optimize portfolio performance. Across four m
ajor equity markets, our method achieves competitive and often superior out-of-s
ample Sharpe ratios compared with historical and prediction-focused baselines, w
ith particularly strong gains in larger asset universes. Our code is publicly av
ailable.

Action Manifold Smoothing: A Lipschitz Pathway Perspective on High-Dimensional R
einforcement Learning
Zhihao Lin
High-dimensional continuous control remains challenging in deep reinforcement

learning, where algorithms like TD3 and SAC often collapse.
We propose a unifying \textbf{Lipschitz Pathway} framework that decomposes instability into four amplification stages,
namely action parameterization (L_1),
dynamics sensitivity (L_2),
Q-network curvature (L_3),
and temporal-difference (TD) target stability (L_4),
where errors compound multiplicatively along the learning pipeline. Our analysis identifies a \textit{discrete-continuous mismatch} as the root cause:
value functions trained from sparse point samples must generalize over continuous
manifolds, leading to multiplicative error amplification along the pathway. To address this, we introduce \textbf{Action Manifold Smoothing (AMS)}, which
replaces point-wise TD targets with orthogonally-sampled neighborhood averages, jointly regularizing L_3 (via implicit Laplacian smoothing) and L_4
(via local manifold supervision). We further characterize when Lipschitz-constrained
Q-networks and geometric action priors are beneficial based on task structure. Empirically, AMS enables both TD3 and SAC to achieve over 400 reward on the 38-D Dog Run task within 1M steps, where baselines fail.
These results validate the Lipschitz pathway as a principled framework for diagnosing and solving stability bottlenecks in high-dimensional control.

Unveiling the Structure of Do-Calculus Reasoning via Derivation Graphs
Clément Yvernes, Emilie Devijver, Marianne Clausel, Eric Gaussier
The do-calculus defines a general system of inference for interventional queries, allowing causal quantities to be transformed through successive applications of its rules. This process induces a rich space of equivalent interventional expressions, but combining and ordering these rules remains challenging.
In this work, we introduce derivation graphs, which represent how do-calculus rules are applied and combined, and characterize the full space of observational and interventional probabilities which are equivalent under the do-calculus. The structure of these graphs yields a simple procedure that uses at most four applications of do-calculus rules.
Finally, we show how applying identification algorithms to equivalent causal queries produces multiple valid estimands for the same causal quantity, eventually yielding more efficient estimators.
****

Edge-colored Clustering in Hypergraphs: A MaxECC Approximation
Aravind Srinivasan, Arushi Srinivasan, Jiayi Wu
We study the MaxECC problem, where given an edge-colored hypergraph with k colors and edge size r, we seek to color the vertices of the graph in order to maximize the number of satisfied edges (edges having the same color as their extremities): this is an effective mechanism for clustering (coloring) objects based on their multi-way interactions with one another in a system, providing significant applications in machine learning, clustering, and data mining. We exponentially improve upon the approximation ratio of an existing algorithm to $\frac{1}{r+1}$, present another novel dependent-rounding algorithm with an approximation ratio of $1/ \lceil \frac{k}{2}\rceil$, and modify the initial algorithm via analytical scaling techniques in order to achieve an approximation factor of $(1-e^{-r})/r$. We then apply our scaling algorithm to graph MaxECC and improve the best-known approximation factor for all hypergraphs: in particular, our algorithm provides an approximation factor of 0.43 as opposed to the previously-known 0.38 factor for graphs.

TimeGuard: Channel-wise Pool Training for Backdoor Defense in Time Series Forecasting
Quang Duc Nguyen, Siyuan Liang, Yiming Li, Fushuo Huo, Dacheng Tao
Time Series Forecasting (TSF) is highly vulnerable to backdoor attacks, yet effective defenses remain underexplored due to challenges arising from data entangle

ment and shifts in task formulation. To fill this gap, we conduct a systematic evaluation of thirteen representative backdoor defenses across the TSF life cycle and analyze their failure modes. Our results reveal two fundamental issues: (1) data entanglement induces *channel-level signal dilution*, rendering sample-filtering and trigger-synthesis defenses ineffective at localizing backdoors; and (2) task-formulation shift leads to *training-loss degeneration*, causing poisoned and clean windows to become indistinguishable at training stages. Based on these findings, we propose a training-time backdoor defense for TSF, termed TimeGuard. Our method adopts channel-wise pool training as the core paradigm and initializes a high-confidence pool using time-aware criteria to mitigate signal dilution. Moreover, we introduce distance-regularized loss selection to progressively expand the reliable pool during training and ease loss degeneration. Extensive experiments across multiple datasets, forecasting architectures, and TSF backdoor attacks demonstrate that TimeGuard substantially improves robustness, boosting $\mathrm{MAE}_ \mathrm{P}$ by $1.96\times$ over the leading baseline, while preserving clean performance within 5% $\mathrm{MAE}_ \mathrm{C}$.

Complexity of Decentralized Optimization with Mixed Affine Constraints
Demyan Yarmoshik, Nhat Trung Nguyen, Alexander Rogozin, Alexander Gasnikov
This paper considers decentralized optimization of convex functions with mixed affine equality constraints involving both local and global variables. Constraints on global variables may vary across different nodes in the network, while local variables are subject to coupled and node-specific constraints. Such problem formulations arise in machine learning applications, including federated learning and multi-task learning, as well as in resource allocation and distributed control. We analyze this problem under smooth and non-smooth assumptions, considering both strongly convex and general convex objective functions. Our main contribution is an optimal algorithm for the smooth, strongly convex regime, whose convergence rate matches established lower complexity bounds. We further provide optimal and near-optimal methods for the remaining cases.

LiME: Lightweight Mixture of Experts for Efficient Multimodal Multi-task Learning
Md Kowsher, Haris Mansoor, Nusrat Jahan Prottasha, Ozlem Garibay, Victor Zhu, Zhengping Ji, Chen Chen
MoE-PEFT methods combine Mixture of Experts with parameter-efficient fine-tuning for multi-task adaptation, but require separate adapters per expert—causing trainable parameters to scale linearly with expert count and limiting applicability to adapter-based architectures. We propose LiME (Lightweight Mixture of Experts), which achieves expert specialization through lightweight modulation rather than adapter replication. Instead of separate adapters, LiME uses a single shared PEFT module and modulates its output with lightweight expert vectors, reducing expert parameters while generalizing to any PEFT method. Notably, LiME introduces zero-parameter routing by leveraging existing frozen and adapted representations—eliminating learned router parameters typically required per layer. Theoretically, we prove that (i) more experts preserve more task-relevant information and (ii) modulation approximates full expert-specific PEFT with bounded error. LiME further incorporates n-gram windowed routing and adaptive expert selection (Auto Top-K) based on routing confidence. Experiments on MMT-47, a multimodal multi-task benchmark with 47 tasks spanning text, image, and video, demonstrate that LiME achieves competitive or superior performance while using up to 4× fewer trainable parameters and up to 29% faster training compared to corresponding MoE-PEFT baselines.

MaMa: A Game-Theoretic Approach for Designing Safe Agentic Systems
Jonathan Nöther, Adish Singla, Goran Radanovic
LLM-based multi-agent systems have demonstrated impressive capabilities, but they also introduce significant safety risks when individual agents fail or behave adversarially. In this work, we study the automated design of agentic systems that remain safe even when a subset of agents is compromised. Inspired by Stackelb

erg security games, we formalize this problem as a game between a system designe r (the Meta-Agent) and a best-responding Meta-Adversary that selects and comprom ises a subset of agents to minimize safety. We propose Meta-Adversary–Meta-Agent (MaMa), a novel algorithm inspired by this formalization for automatically desi gning safe agentic systems. Our approach uses LLM-based adversarial search, wher e the Meta-Agent iteratively proposes system designs and receives feedback based on the strongest attacks discovered by the Meta-Adversary. Empirical evaluation s across diverse environments show that systems designed with MaMa consistently defend against worst-case attacks while maintaining performance comparable to sy stems optimized solely for task success. Moreover, the resulting systems general ize to stronger adversaries, as well as ones with different attack objectives or underlying LLMs, demonstrating robust safety beyond the training setting. Code is available at https://github.com/JNoether/MaMa

Learning to Move Before Learning to Do: Task-Agnostic pretraining for VLAs
Junhao Shi, Siyin Wang, Xiaopeng Yu, Li Ji, Jingjing Gong, Xipeng Qiu
Vision-Language-Action (VLA) models are bottlenecked by the scarcity of expert d emonstrations—expensive triplets of observations, language instructions, and act ions. We propose that learning ''how to move'' can be decoupled from learning '' what to do,'' and that the former requires no task labels at all. Our two-stage framework, **Task-Agnostic Pretraining (TAP)** first pre-trains on abundant, che ap *task-agnostic* data (discarded off-task trajectories or autonomous robot pla y) using an Inverse Dynamics objective that predicts actions from consecutive ob servations. This self-supervised phase instills physical affordances—grasping, c ontact dynamics, end-effector control—without human annotation. A lightweight se cond stage then aligns these physical priors with language instructions using mi nimal expert data. On the SIMPLER benchmark, our approach matches models trained on 1M+ expert trajectories while using orders of magnitude less labeled data, a chieving a 10\% absolute gain over standard behavior cloning. In real-world Wido wX experiments, it surpasses internet-scale baselines under visual distribution shifts (e.g., 25\% vs. 0\% under camera perturbations), demonstrating that task-agnostic pretraining yields robust, transferable physical representations for Em bodied AI.

JADE: Bridging the Strategic-Operational Gap in Dynamic Agentic RAG
Yiqun Chen, Erhan Zhang, Tianyi Hu, Shijie Wang, Zixuan Yang, Meizhi Zhong, Xiao chi Wei, Yan Gao, Yi Wu, Yao Hu, Jiaxin Mao
The evolution of Retrieval-Augmented Generation (RAG) has shifted from static re trieval pipelines to dynamic, agentic workflows where a central planner orchestr ates multi-turn reasoning. However, existing paradigms face a critical dichotomy : they either jointly optimize modules within rigid, fixed-graph architectures, or enable dynamic planning while treating executors as frozen, black-box tools. We identify that this \textit{decoupled optimization} creates a ``strategic-oper ational mismatch,'' where sophisticated planning strategies fail to materialize due to unadapted local executors, often causing negative gains despite increased system complexity. In this paper, we propose \textbf{JADE} (\textbf{J}oint \tex tbf{A}gentic \textbf{D}ynamic \textbf{E}xecution), a unified framework for joint optimization of planning and execution within dynamic, multi-turn workflows. By modeling the system as a cooperative multi-agent team with a shared backbone, J ADE enables end-to-end learning driven by outcome-based rewards. This approach f acilitates \textit{co-adaptation}: the planner learns to operate within executor capability boundaries, while executors evolve to align with strategic intent. Empirical results demonstrate that JADE transforms disjoint modules into a syner gistic system, yielding strong performance improvements via joint optimization a nd enabling a flexible balance between efficiency and effectiveness through dyna mic workflow orchestration.

Salus: Strategic Diagnostic Testing for Complex Diagnosis via Multi-Agent Reinfo rcement Learning
Shuohao Gao, Xuanzhong Chen, Lingxiao Luo, Zilin Ding, Rong Han, Rui Jiang, Ting

Chen
Diagnosing complex diseases is inherently a sequential and iterative medical investigation process, in which a clinician strategically requests multiple rounds of diagnostic tests to differentiate among similar diseases until reaching a definitive diagnosis.
Although large language models show great potential as clinical assistants, they often struggle to navigate this complex interactive process, suffering from premature diagnostic closure. Furthermore, optimizing LLMs for such multi-round environments is frequently hindered by the challenge of reward sparsity and hacking.
In this paper, we introduce $\textbf{CompDiag-Bench}$, a benchmark that formalizes diagnosis as a sequential decision-making process where a clinician must strategically request diagnostic tests from a dynamic environment in order to reach a definitive diagnosis.
To address this task, we propose $\texttt{Salus}$, a multi-agent framework that decouples diagnostic reasoning into three specialized functional roles: a Differential Reasoner, a Strategic Controller, and a Workup Proposer.
$\texttt{Salus}$ is optimized via multi-agent reinforcement learning employing structured rewards to calibrate strategic diagnostic behavior.
Specifically, we leverage an LLM-as-a-Judge reward mechanism to provide dense, semantically-grounded feedback, designed to penalize premature closure and incentivize accurate differential diagnoses.
Experimental results show that our model, $\texttt{Salus-7B}$, attains state-of-the-art Top-1 accuracy of 83.64% on complex cases, outperforming DeepSeek-V3.2 (71.38%) and achieving performance on par with GPT-5.2 (80.30%).
****
Accelerated Dual Method for Distributed Optimization: An Inexact-Gradient View of Local Updates
Junchi YANG, Ziyang Zeng, Pan Linxuan, Murat Yildirim, Feng Qiu
In distributed machine learning, efficiently training across multiple agents with heterogeneous data distributions remains a central challenge. We address the problem of stochastic, strongly convex distributed optimization by applying accelerated gradient ascent to the dual variables and multi-step stochastic gradient descent (SGD) to the primal variables in the Lagrangian formulation. This approach naturally enables local computation, as the inner SGD loops require no inter-agent communication. We prove that the method converges for any number of local updates, attaining the optimal communication complexity when local computation is sufficient. Our analysis builds on an inexact accelerated gradient framework, where the partial gradient of the Lagrangian with respect to the dual variables is treated as an inexact gradient of the dual function. A notable byproduct of this framework is an algorithm that achieves optimal reproducibility guarantees under biased gradient estimates.
****
Amortized Variational Inference for Partial-Label Learning: A Probabilistic Approach to Label Disambiguation
Tobias Fuchs, Nadja Klein
Real-world data is frequently noisy and ambiguous. In crowdsourcing, for example, human annotators may assign conflicting class labels to the same instances. Partial-label learning (PLL) addresses this challenge by training classifiers when each instance is associated with a set of candidate labels, only one of which is correct. While early PLL methods approximate the true label posterior, they are often computationally intensive. Recent deep learning approaches improve scalability but rely on surrogate losses and heuristic label refinement. We introduce a novel probabilistic framework that directly approximates the posterior distribution over true labels using amortized variational inference. Our method employs neural networks to predict variational parameters from input data, enabling efficient inference. This approach combines the expressiveness of deep learning with the rigor of probabilistic modeling, while remaining architecture-agnostic. Theoretical analysis and extensive experiments on synthetic and real-world datasets demonstrate that our method achieves state-of-the-art performance in both acc

uracy and efficiency.
****
You Don't Protect if You Don't Expect: Breaking the Key Assumption behind CLIP's Test-Time Defenses
Ruize Zhang, Yu Li, Zhang Wan, Juan Cao, Jie Zhang, Sheng Tang
Recent test-time defenses for CLIP claim to preserve zero-shot clean accuracy while improving adversarial robustness. However, we find the reported robustness of six recent proposed state-of-the-art methods substantially overestimated: they fail under basic adaptive attacks. We further observe that these defenses share a common reliance on an indicative measurement that is assumed to capture the distributional difference between clean and adversarial samples and to determine whether the defense should preserve or alter the static model's prediction. We argue that this assumption is the fundamental weakness, and we propose CLIP-MAD (Manipulating Assumed Difference), an adaptive attack strategy designed to break it. CLIP-MAD efficiently expands the adversarial distribution without costly full gradient calculations and can be flexibly combined with existing attack baselines to further boost attack strength. Experiments across 13 datasets demonstrate that CLIP-MAD produces strong adversarial samples that markedly reduce the robustness of diverse test-time defenses, revealing a false sense of security in CLIP’s zero-shot robustness. Code will be available at https://github.com/rzzhang222/CLIP-MAD.

TadA-Bench: A Million-Variant Benchmark for Future-Round Discovery Toward Agentic Protein Engineering
Jin Gao, Juntu Zhao, Zirui Zeng, Jiaqi Shen, Junhao Shi, Dukun Zhao, Yuming Lu, Dequan Wang
AI for scientific discovery is entering an agentic era, where protein-engineering systems are expected to prioritize future wet-lab experiments rather than merely fit static measurements.
We introduce TadA-Bench, a million-variant wet-lab replay benchmark from 31 TadA directed-evolution rounds for future-round discovery toward agentic protein engineering.
TadA-Bench preserves the campaign chronology and defines a fixed-data replay task: given earlier experimental rounds, models rank variants that appear only in later rounds.
It provides aligned DNA, RNA, and protein views, and uses Seq2Graph, a graph-based label-unification pipeline, to reconcile noisy enrichment measurements into consistent cross-round activity labels.
Random-split controls show strong interpolation, but future-round ranking and finite-budget candidate selection are much weaker.
Controlled analyses suggest that evolutionary coverage is more informative than local data density, positioning TadA-Bench as a reproducible wet-lab replay substrate for future-round discovery toward agentic protein engineering; the data and code are released on Hugging Face and GitHub.

Speech-Audio Compositional Attacks on Multimodal LLMs and Their Defense with SALMONN-Guard
Yudong Yang, Xuezhen Zhang, Zhifeng Han, Siyin Wang, Jimin Zhuang, Zengrui Jin, Jing Shao, Guangzhi Sun, Chao Zhang
Recent progress in large language models (LLMs) has enabled understanding of both speech and non-speech audio, but has also exposed new safety risks arising from complex audio inputs that are inadequately handled by current safeguards. We introduce SACRED-Bench (Speech–Audio Composition for RED-teaming) to evaluate the robustness of LLMs under complex audio-based attacks. Unlike existing perturbation-based methods that rely on noise optimization or white-box access, SACRED-Bench exploits speech–audio composition to enable effective black-box attacks. SACRED-Bench adopts three composition mechanisms: (a) speech overlap, (b) multi-speaker dialogue, and (c) mixtures of speech and non-speech audio. These mechanisms focus on evaluating safety in settings where benign and harmful intents co-occur within a single auditory scene. Moreover, questions in SACRED-Bench are design

ed to implicitly refer to content in the audio, such that no explicit harmful in
formation appears in the text prompt alone.
Experiments demonstrate that even Gemini 2.5 Pro, a state-of-the-art proprietary
 LLM with safety guardrails fully enabled, still exhibits a 66% attack success r
ate. To bridge this gap, we propose SALMONN-Guard, the first guard model that jo
intly inspects speech, audio, and text for safety judgments, reducing the attack
 success rate to 20\%. Our results highlight the need for audio-aware defenses t
o ensure the safety of multimodal LLMs.

The Geometry of Sequential Learning: Lie-Bracket Prediction of Transfer Order
John Sweeney
Sequential learning is order-dependent: from Pile-style next-token domain adapta
tion to instruction-SFT and DPO, N candidate sources induce $N!$ possible curr
icula. We show that the local order effect is governed by a computable geometric
 quantity, the Lie-bracket commutator of gradient update fields, yielding a pair
wise score for whether $A \to B$ or $B \to A$ is better for a target domain. The
 pairwise bracket primitive also defines a *Lie-Bracket Tournament*: with a shar
ed θ_0 target-gradient reference, Hessian symmetry gives Borda/row-sum sc
ores from one Hessian-vector product per source, $O(N)$ dot products, and an $O(
N\log N)$ sort, without materializing the $O(N^2)$ edge matrix. Empirically, the
 planner reaches 98.1%/98.9% pairwise accuracy at $k=1$ for instruction-SFT/DPO,
 remains at 73.1%/72.2% at $k=20$, and preserves the original pretraining-domain
 evidence with 82.4–92.0% accuracy across four LLMs and 91.1% on diffusion. At c
urriculum scale, it recovers the best of all $3!$ schedules in 87.5% of trials,
ranks 85 Stack programming-language source domains for a Python target in the 99
th sampled percentile, and reaches the 99.0–99.6th sampled percentile on 56 MMLU
 subjects, sharply above the reported descending gradient-norm baseline. These r
esults reframe sequential learning as a geometric tournament problem: commutator
s provide both local pairwise order information and a scalable primitive for man
y-domain schedules.

DiffCrossGait: Trajectory-Level Alignment for 2D-3D Cross-Modal Gait Recognition
 via Latent Diffusion
Zhiyang Lu, Ming Cheng
Cross-modal 2D–3D gait recognition is impeded by inherent domain discrepancies b
etween 2D silhouette and 3D point cloud distributions. While prior methods align
 only final embeddings, we propose DiffCrossGait, which enforces trajectory-leve
l alignment by driving both modalities with shared noise in a unified latent dif
fusion process. By driving both modalities with shared Gaussian noise within a l
atent space, we enable continuous alignment throughout the generative evolution.
 We introduce a Tri-Phase Alignment Strategy that exploits varying noise intensi
ties to enforce identity anchoring, dynamics consistency, and cross-modal struct
ural recoverability, thereby constraining both modalities to share denoising dyn
amics and bottleneck structure, which promotes modality-invariant gait features.
 Crucially, our framework decouples generative alignment from the discriminative
 backbone; the diffusion mechanism serves exclusively as a training objective, e
nsuring high inference efficiency by eliminating the computational overhead of i
terative denoising. Extensive experiments on the SUSTech1K and FreeGait benchmar
ks demonstrate that DiffCrossGait achieves state-of-the-art performance.

Let the Prototype Guide You: Robust Aggregation of Sparse Multi-Class Annotation
s via Annotator Prototype Learning
Ju Chen, Jun Feng, Shenyu Zhang
Truth inference is a critical technique for aggregating noisy and biased multi-c
lass classification annotations. State-of-the-art approaches model each annotato
r using an individual confusion matrix. While well-grounded, they suffer from tw
o fundamental bottlenecks: 1) confusion matrices are underfit when annotators la
bel only a small subset of tasks or when classes are imbalanced, and 2) a single
 confusion matrix per annotator is inadequate for capturing complex annotator be
haviors, leading to class-level collapse when tasks are extremely difficult. Sim

ultaneously addressing these challenges is non-trivial, as it demands both robustness to data sparsity and sufficient expressiveness for complex annotator patterns. In this paper, we propose \textbf{CPBCC} (\textbf{C}lass-specific \textbf{P}rototype-driven \textbf{B}ayesian \textbf{C}lassifier \textbf{C}ombination), which creatively models annotators through a dual-pathway architecture: (i) learning class-specific prototype annotation patterns across all annotators, and (ii) learning annotator-specific weights over prototypes. This framework addresses the bottlenecks and achieves a robust yet rich annotator characterization. Experiments across 10 real-world datasets spanning five domains demonstrate that CPBCC yields a 26\% accuracy improvement in the best case, and boosts average accuracy from 68.73\% to 74.11\%. Our source code is available at \url{https://github.com/JuJuCHEN-HHU/CPBCC_PTBCC}.

X-MoGe: A Cross-Modal Adaptation Framework with Mixture-of-Experts and Geometry Guidance for Heterogeneous Collaborative Perception
Wenkai Lin, Zhihong Liu, Chenglu Wen
Multi-agent collaborative perception improves perception range and robustness in autonomous driving. However, most existing methods assume homogeneous sensors and perception networks, which is unrealistic in real-world heterogeneous systems. Differences in sensing modalities and independently trained models lead to significant semantic and geometric inconsistencies, limiting effective collaboration. To solve these problems, we propose a novel cross-modal adaptation framework with Mixture-of-Experts and geometry-guided fusion for heterogeneous collaborative perception, named X-MoGe. Specifically, we propose a Pixel-level Mixture-of-Experts (P-MoE) module, which adaptively models modality-specific semantic characteristics under heterogeneous sensing conditions. In addition, a geometry-guided feature fusion module incorporates explicit geometric priors to enforce spatial alignment and consistency in the BEV space. Extensive experiments on OPV2V and DAIR-V2X datasets demonstrate that the proposed method achieves state-of-the-art performance in heterogeneous collaborative perception.

Data-Source Adaptive Online Learning under Heteroscedastic Noise
Amith Bhat Hosadurga Anand, Haipeng Luo, Aadirupa Saha
In this paper, we address the standard K-armed multi-armed bandit (MAB) with heterogeneous data sources, each exhibiting unknown and distinct noise variances, $\lbrace \sigma_j^2 \rbrace_{j=1}^{M}$. The learner performs standard regret minimization, with the added challenge of choosing which data source to query at each round. We propose SOAR (Source-Optimistic Adaptive Regret minimization), a novel algorithm that adaptively balances exploration and exploitation by jointly constructing upper confidence bounds for arm rewards and lower confidence bounds for data source variances. Our theoretical analysis establishes that SOAR achieves a regret bound of $\tilde{O}\left({\sigma^\star}^2 \sum_{i=2}^K \tfrac{1}{\Delta_i}\right),$ along with a preprocessing cost that depends only on the problem parameters $\lbrace \sigma_j \rbrace_{j=1}^{M}$, K, and grows at most logarithmically with the horizon T; where ${\sigma^\star}^2$ is the minimum source variance, and Δ_i denotes the suboptimality-gap of the i-th arm reward. The $\tilde{O}(\cdot)$ notation hides the polylogarithmic factors in these problem parameters. Notably, despite not knowing the minimum-variance source, SOAR matches the instance-dependent regret of a standard MAB run on a single source of variance $\sigma^\star$. This near-optimal instance-dependent regret analysis of SOAR underscores its effectiveness in dynamically managing heteroscedastic noise without incurring significant overhead. Experiments on synthetic problem instances as well as a real dataset (MovieLens 32M) demonstrate that our method significantly outperforms baseline bandit algorithms in terms of regret performance. Our work opens a new direction for adaptively leveraging multiple heterogeneous data sources, extending beyond traditional bandit frameworks.

KUMA: A Novel Framework with Koopman Separation and Efficient Multilevel Extraction in Time Series Forecasting
Sijie Xiong, Cheng Tang, Atsushi Shimada

Time series forecasting plays a crucial role in a wide range of real-world applications and has become increasingly complex with the growth of multivariate dimensions and extended historical observations, leading to the prosperity of deep forecasting models. Previous models are hindered by three major challenges: high computational complexity, inefficient token utilization caused by redundancy and scarcity, and temporal distribution shifts resulting from non-stationary dynamics. Inspired by Koopman theory and the success of multilevel encoder–decoder architectures with skip connections, we design an input-dependent Koopman module to decompose time series into Koopman dynamics and residual dynamics. Building upon this formulation, we propose a U-shaped Multilevel Attention module (UMA) that integrates element-wise attention filtering and linear attention, giving rise to KUMA. The input-dependent Koopman operator mitigates the issue of operator mixture and alleviates temporal distribution shifts, while UMA achieves a favorable balance between token redundancy and token scarcity with acceptable computational efficiency. Comprehensive evaluations across 12 benchmark datasets demonstrate that KUMA achieves superior performance compared to existing excellent approaches.

Local Linearity of LLMs Enables Activation Steering via Model-Based Linear Optimal Control
Julian Skifstad, Xinyue Annie Yang, Glen Chou
Inference-time LLM alignment methods, particularly activation steering, offer an alternative to fine-tuning by directly modifying activations during generation. Existing methods, however, often rely on non-anticipative interventions that ignore how perturbations propagate through transformer layers and lack online error feedback, resulting in suboptimal, open-loop control. To address this, we show empirically that layer-wise dynamics across multiple LLM architectures and scales are well-approximated by locally-linear models, despite the nonlinear structure of transformer blocks. Exploiting this property, we model LLM inference as a linear time-varying dynamical system and adapt the classical linear quadratic regulator to compute feedback controllers using layer-wise Jacobians, steering activations toward desired semantic setpoints in closed-loop with minimal computational overhead and no offline training. We also derive theoretical bounds on setpoint tracking error, enabling formal guarantees on steering performance. Using a novel adaptive semantic feature setpoint signal, our method yields robust, fine-grained behavior control across models, scales, and tasks, including state-of-the-art modulation of toxicity, truthfulness, refusal, and arbitrary concepts, surpassing baseline steering methods.

How2Everything: Mining the Web for How-to Procedures to Evaluate and Improve LLMs
Yapei Chang, Kyle Lo, Mohit Iyyer, Luca Soldaini
Generating step-by-step "how-to" procedures is a key LLM capability: how-to advice is commonly requested in chatbots, and step-by-step planning is critical for complex reasoning tasks.
Yet, measuring and improving procedural validity at scale on real-world tasks remains challenging and understudied.
We introduce How2Everything, a scalable framework to evaluate and improve goal-conditioned procedure generation.
Our pipeline How2Mine extracts and rewrites 351K procedures from 980K web pages across 14 topics, and can scale to larger corpora.
From this pool we build How2Bench, a 7K-example evaluation set balanced across topics.
We also introduce How2Score, an evaluation protocol that uses an LLM judge to detect whether a generation contains any critical failure that would prevent achieving the goal.
For low-cost, reproducible evaluation, we distill a frontier judge into an open 8B model achieving 80.5\% agreement with human annotators.
How2Bench reveals clear scaling trends across model size and training stages, providing signal early in pretraining.

Finally, RL using How2Score as a reward improves performance on How2Bench by >10 points across three base models without systematic regressions on standard benchmarks, with gains not primarily explained by source-document memorization or superficial format compliance.
We release all code and data at https://github.com/lilakk/how2everything.

A Noise Sensitivity Exponent Controls Large Statistical-to-Computational Gaps in Single- and Multi-Index Models
Leonardo Defilippis, Florent Krzakala, Bruno Loureiro, Antoine Maillard
Understanding when learning is statistically possible yet computationally hard is a central challenge in high-dimensional statistics.
In this work, we investigate this question in the context of single- and multi-index models, classes of functions widely studied as benchmarks to probe the ability of machine learning methods to discover features in high-dimensional data.
Our main contribution is to show that a Noise Sensitivity Exponent (NSE)—a simple quantity determined by the activation function—governs the existence and magnitude of statistical-to-computational gaps within a broad regime of these models.
We first establish that, in single-index models with large additive noise, the onset of a computational bottleneck is fully characterized by the NSE. We then demonstrate that the same exponent controls a statistical-computational gap in the specialization transition of large separable multi-index models, where individual components become learnable. Taken together, our results identify the NSE as a unifying property linking noise robustness, computational hardness, and feature specialization in high-dimensional learning.

Compositional Generative Modeling from Decentralized Data
Mashrur M. Morshed, Vishnu Boddeti
Learning the compositional nature of the physical world requires joint observation of interacting factors.
However, because practical data is often decentralized, these factors are fragmented across isolated silos.
Existing decentralized generative approaches focus only on modeling the union of siloed data, overlooking novel combinations implied by the collective whole.
To bridge this gap, we introduce Decentralized Compositional Flow Matching (DCFM), a framework that enforces structural constraints across the global set of generative factors, without exchanging any raw data. DCFM enables novel combinations to emerge through peer interactions, even when no single data source can independently support the composition. Empirically, DCFM substantially outperforms federated learning and mixture-of-experts baselines across conditional image generation, robotic spatial planning, and medical attribute co-occurrence modeling.

Delayed Momentum Aggregation: Communication-efficient Byzantine-robust Federated Learning with Partial Participation
Kaoru Otsuka, Yuki Takezawa, Makoto Yamada
Partial participation is essential for communication-efficient federated learning at scale, yet existing Byzantine-robust methods typically assume full client participation.
In the partial participation setting, a majority of the sampled clients may be Byzantine, once Byzantine clients dominate, existing methods break down immediately.
We introduce delayed momentum aggregation, a principle where the central server aggregates cached momentum from non-sampled clients along with fresh momentum from sampled clients.
This principle ensures Byzantine clients remain a minority from the server's perspective even when they dominate the sampled set.
We instantiate this principle in our optimizer DeMoA.
We analyze the convergence rate of DeMoA, showing that DeMoA is Byzantine-robust under partial participation.
Experiments show that, with 20% Byzantine ratio and only 10% partial participation rate, DeMoA achieves the best accuracy even when existing methods fail empiri

cally.

When More Data Doesn't Help: Limits of Adaptation in Multitask Learning
Steve Hanneke, Mingyue Xu
Multitask learning and related frameworks have achieved tremendous success in modern applications. In multitask learning problem, we are given a set of heterogeneous datasets collected from related source tasks and hope to enhance the performance above what we could hope to achieve by solving each of them individually. The recent work of Hanneke & Kpotufe (2022) has showed that, without access to distributional information, no algorithm based on aggregating samples alone can guarantee optimal risk as long as the sample size per task is bounded.

In this paper, we focus on understanding the statistical limits of multitask learning. We go beyond the no-free-lunch theorem in Hanneke & Kpotufe (2022) by establishing a stronger impossibility result of adaptation that holds for arbitrarily large sample size per task. This improvement conveys an important message that the hardness of multitask learning cannot be overcame by having abundant data per task. We also discuss the notion of optimal adaptivity that may be of future interests.
****
Multimodal Fusion via Self-Consistent Task-Gradient Fields
Jiayu Xiong, Jing Wang, Jun Xue, Wanlong Wang, Jianlong Kwan, Xiaosen Lyu, Zhouqiang Jiang
Multimodal learning aims to preserve as much task-related information as possible from different inputs. However, current fusion designs often distort the feedback loop to feature extractors. Aggressively merging modalities entangles their representations, making the feature extractors fragile to incomplete inputs. Meanwhile, attempting to separate features via auxiliary losses frequently introduces optimization conflicts that distract from the primary task. We propose the Self-Consistent Field Autoencoder (SCFAE) to provide a better path for task gradients. Our method follows the self-consistent field principle to balance task learning with feature organization, thereby minimizing mutual information. We use small autoencoders for each modality to keep information intact. The task loss acts as a driving force to select predictive features. The reconstruction loss acts as a constraint to separate these features into independent subspaces. These dual objectives operate through complementary feature subspaces, thereby mitigating optimization interference. We evaluate SCFAE on audio-visual-text, audio-visual, and image-video benchmarks. Results show that SCFAE handles missing data and unequal input sizes more robustly via a simple structure. Gradient analysis confirms that SCFAE avoids conflicts and maintains stable training dynamics.

Identifying Partially Observed Causal Models from Heterogeneous/Nonstationary Data
Xinshuai Dong, Haoyue Dai, Ignavier Ng, Peter Spirtes, Kun Zhang
Estimating causal structure in the presence of latent variables is an important yet challenging problem. Recent works have shown that distributional constraints, such as rank deficiency constraints of the covariance matrices, can be exploited to recover the underlying causal structure involving latent variables. However, real-world data often exhibit heterogeneity/nonstationarity, which pose challenges to existing methods. In this work, we develop a principled approach for identifying the structure of partially observed linear causal models from heterogenous/nonstationary data. We first formulate a class of heterogenous/nonstationary, partially observed linear causal models and prove that their distributional constraints are equivalent to those in the homogeneous case. Building on this, we propose a novel rank deficiency test that can efficiently handle heterogenous/nonstationary data, and further establish identifiability results for recovering the causal structure involving latent variables. We also provide a method to identify which variables exhibit distribution shifts, i.e., whose causal mechanisms vary across domains. Experiments on simulated and real-world data validate our theoretical findings and the effectiveness of our method.

Decouple and Cache: KV Cache Construction for Streaming Video Understanding
Zhanzhong Pang, Dibyadip Chatterjee, Fadime Sener, Angela Yao
Streaming video understanding requires processing unbounded video streams with l imited memory and computation, posing two key challenges. First, continuously co nstructing new and evicting old key-value(KV) caches is required for unbounded s treams. Secondly, due to the high cost of collecting and training on unbounded s treams, models must learn from short sequences while generalizing to long stream s. Existing streaming VideoVLLMs fail to scale to unbounded video streams or foc us on cache reuse strategies, leaving the impact of cache construction underexpl ored. In this paper, we propose Decoupled Streaming Cache(DSCache), a training-f ree cache construction mechanism that adapts pretrained offline models to stream ing settings. DSCache maintains a cumulative past KV cache while constructing a separate instant cache on-demand, decoupled from past caches to preserve the inf ormativeness of recent inputs. To enable position extrapolation beyond the train ing length, DSCache further incorporates a position-agnostic encoding strategy, ensuring KV caches to support unseen positions and preventing position overflow. Experiments on Streaming Video QA benchmarks demonstrate DSCache's state-of-the -art performance, with an average 2.5% accuracy gains over prior methods.

Fine-Tuning of Transformer models with Frames
Harshavardhan Adepu, Li Zhang, Sanjiv Kumar, Vikas Singh
Parameter-Efficient Fine-Tuning (PEFT) strategies such as Low-Rank Adaptation (L oRA) are effective solutions for fine-tuning large-scale pre-trained models; how ever,
their memory requirements scales with the size of the model, $\mathcal{O}(dr)$, where d is the model's hidden dimension and r is the rank.
Our proposal, FrameFT,
models the parameter update ΔW with a sparse coefficient matrix in a Fus ion Frame basis.
Fusion Frames can be generated algorithmically and shared across model layers, e nabling highly efficient updates.
Only the sparse coefficients of the basis expansion are stored/optimized, strong ly reducing the memory footprint and parameter count.
The sparse structure of the coefficient matrix in FrameFT and the sparsity in th e Fusion Frames, give sizable compute benefits.
Our technical analysis shows that FrameFT allows obtaining formal convergence re sults.
We evaluate our method across a suite of supervised fine-tuning benchmarks, prim arily focusing on language tasks, but also report applicability to vision models . Our empirical evaluations show that FrameFT achieves performance on par with o r exceeding state-of-the-art PEFT techniques, but needs far fewer trainable para meters and less memory.

Multimodal Function Vectors for Visual Relations
Shuhao Fu, Esther A Goldberg, Ying Nian Wu, Hongjing Lu
Large Multimodal Models (LMMs) demonstrate impressive in-context learning abilit ies from few multimodal demonstrations, yet the internal mechanisms supporting s uch task learning remain opaque. Building on prior work of Large Language Models , we show that a small subset of attention heads in Large Multimodal Models is r esponsible for transmitting representations of visual relations. The activations of these attention heads, termed $\textit{function vectors}$, can be extracted and manipulated to alter an LMM’s performance on relational tasks. First, using synthetic and real image datasets, we apply causal mediation analysis to identif y attention heads that strongly influence relational predictions, and extract mu ltimodal function vectors that improve zero-shot accuracy at inference time. We further demonstrate that these multimodal function vectors can be fine-tuned wit h a modest amount of training data, while keeping LMM parameters frozen, to sign ificantly outperform in-context learning baselines. Finally, we show that relati on-specific function vectors can be linearly combined to solve analogy problems

involving novel and untrained visual relations, highlighting the strong generalization ability of this approach. Through experiments on two LMMs, including Open Flamingo and Qwen3-VL, our results show that these models encode visual relational knowledge within localized internal structures, which can be systematically extracted and optimized, thereby advancing our understanding of model modularity and enhancing control over relational reasoning in LMMs.

CausalXRL: Explainable Reinforcement Learning through Causal Graph Reasoning
Yanming Zhang, Eric Papenhausen, Klaus Mueller
Reinforcement learning is a powerful paradigm for training autonomous agents and has achieved impressive performance in complex environments. However, this success often comes at the cost of interpretability, diminishing trust and complicating efforts to debug and improve agent behavior. To address these challenges, we introduce CausalXRL, a novel framework for explainable reinforcement learning (XRL). A key feature of CausalXRL is its use of causal graph reasoning, which provides transparent, structured, multi-level explanations of agent decision-making. We validate CausalXRL through comprehensive case studies and a two-part evaluation: (1) a quantitative analysis of explanation fidelity and causal-structure learning efficiency in benchmark RL environments, and (2) a qualitative expert study assessing explainability in the real-time strategy (RTS) benchmark MicroRTS. The quantitative results show that CausalXRL can provide faithful explanations while efficiently learning causal structures, and the qualitative expert study suggests that participants found CausalXRL useful for inspecting high-level RTS strategies.

Constrained Flow Optimization via Sequential Fine-Tuning for Molecular Design
Sven Gutjahr, Riccardo De Santi, Luca Schaufelberger, Kjell Jorner, Andreas Krause
Adapting generative foundation models, in particular diffusion and flow models, to optimize given reward functions (e.g., binding affinity) while satisfying constraints (e.g., molecular synthesizability) is fundamental for their adoption in real-world scientific discovery applications such as molecular design or protein engineering. While recent works have introduced scalable methods for reward-guided fine-tuning of such models via reinforcement learning and control schemes, it remains an open problem how to algorithmically trade-off reward maximization and constraint satisfaction in a reliable and predictable manner. Motivated by this challenge, we first present a rigorous framework for *Constrained Generative Optimization*, which brings an optimization viewpoint to the introduced adaptation problem and retrieves the relevant task of constrained generation as a sub-case. Then, we introduce Constrained Flow Optimization (CFO), an algorithm that automatically and provably balances reward maximization and constraint satisfaction by reducing the original problem to sequential fine-tuning via established, scalable methods. We provide convergence guarantees for constrained generative optimization and constrained generation via CFO. Ultimately, we present an experimental evaluation of CFO on both synthetic, yet illustrative, settings, and a molecular design task. Across these evaluations, CFO achieves consistent increases in reward while ensuring high constraint satisfaction, showcasing its practical utility for constrained generative optimization.

TreeCUA: Efficiently Scaling GUI Automation with Tree-Structured Verifiable Evolution
Deyang Jiang, Jing Huang, Xuanle Zhao, Lei Chen, Liming Zheng, Fanfan Liu, Haibo Qiu, Peng Shi, Zhixiong Zeng
Effectively scaling GUI automation is essential for computer-use agents (CUAs); however, existing work primarily focuses on scaling GUI grounding rather than the more crucial GUI planning, which requires more sophisticated data collection. In reality, the exploration process of a CUA across apps/desktops/web pages typically follows a tree structure, with earlier functional entry points often being explored more frequently.
In this work, we find that organizing large-scale GUI trajectories into tree str

uctures can effectively eliminate redundant exploration costs, while each branch node also provides key reasoning evidence for distinguishing adjacent trajectories.
Therefore, we propose TreeCUA to efficiently scale GUI automation with tree-structured verifiable evolution.
We propose a multi-agent collaborative framework to explore the environment, verify actions, summarize trajectories, and evaluate quality to generate high-quality and scalable GUI trajectories.
To improve efficiency, we devise a novel tree-based topology to store and replay duplicate exploration nodes, and design an adaptive exploration algorithm to balance the depth (i.e., trajectory difficulty) and breadth (i.e., trajectory diversity). Moreover, we develop world knowledge guidance and global memory backtracking to avoid low-quality generation.
Finally, we naturally extend and propose the TreeCUA-DPO method from abundant tree node information, improving GUI planning capability by referring to the branch information of adjacent trajectories.
Experimental results show that TreeCUA and TreeCUA-DPO offer significant improvements, and out-of-domain (OOD) studies further demonstrate strong generalization.
All trajectory node information and code will be open-sourced.

Is Graph Mixup Beneficial? Investigating Interpolation And Empirical Performance of Graph Mixup Methods
Simon Forbat, Rainer Gemulla
Mixup is a widely used data augmentation technique that constructs new training examples by interpolating between existing ones. While simple and effective in domains like vision and language, applying mixup to graph data is non-trivial and there is no independent empirical evidence for its effectiveness. To fill this gap, we conducted an extensive evaluation study following a unified, established evaluation protocol for graph classification. In contrast to prior results, we found that none of the state-of-the-art mixup methods yielded statistically significant improvements over the no-mixup baseline. To obtain further insights, we analyzed the graphs generated from these mixup methods from an interpolation perspective. We found that (i) many mixup methods failed to interpolate well, (ii) high interpolation error led to performance degradation, and (iii) even good interpolation properties did not lead to performance improvements. Our findings question the efficacy of existing graph mixup methods and highlight the need for a more rigorous exploration and evaluation.

Spectral-Informed Neural Networks Outperform Spectral methods in High-dimensional PDEs
Tianchi Yu, Ivan Oseledets
For low-dimensional problems ($d\leq3$), spectral methods can achieve exceptionally high accuracy. For middle-dimensional problems ($4 \leq d \lesssim 10$), spectral methods remain feasible through specific techniques such as sparse grids or hyperbolic cross. However, for high-dimensional problems ($d\gg 10$), spectral methods suffer frome the curse of dimensionality. Physics-informed neural networks (PINNs) have emerged as a promising approach to overcome this challenge, offering scalability to high dimensions, but often suffer from limited accuracy and efficiency. Recently proposed spectral-informed neural networks (SINNs) combine spectral methods with PINNs, operating directly in the spectral domain to avoid spatial derivative computations and to reduce memory consumption. In this work, we introduce Modified SINNs, which integrate coefficient decay scaling and basis embeddings motivated by harmonic analysis to enhance accuracy in high-dimensional problems and enable accurate approximation of unknown spectral coefficients. Numerical experiments on steady and time-dependent partial differential equations demonstrate that Modified SINNs outperform sparse grid spectral methods on middle-dimensional problems with incomplete spectral information and achieve superior accuracy compared to PINNs on high-dimensional problems.

****
Dimensional Collapse in Transformer Attention Outputs: A Challenge for Sparse Dictionary Learning
Junxuan Wang, Xuyang Ge, Wentao Shu, Zhengfu He, Xipeng Qiu
Transformer architectures, and their attention mechanisms in particular, form the foundation of modern large language models. While transformer models are widely believed to operate in high-dimensional hidden spaces, we show that attention outputs are confined to a surprisingly low-dimensional subspace, with an effective dimensionality of only about 60\% of the full space---a phenomenon that is consistently observed across diverse model families and datasets, and arises from overlap among the output subspaces of different attention heads. Critically, we find this low-rank structure as a key factor of the prevalent dead feature problem in sparse dictionary learning, where it creates a mismatch between randomly initialized features and the intrinsic geometry of the activation space. Building on this insight, we propose a subspace-constrained training method for sparse autoencoders (SAEs), initializing feature directions into the active subspace of activations. Our approach reduces dead features from 87\% to below 1\% in Attention Output SAEs with 1M features, and can further extend to other sparse dictionary learning methods. Our findings provide both new insights into the geometry of attention and practical tools for improving sparse dictionary learning in large language models. Code is available at \url{https://github.com/OpenMOSS/Llamascopium}.
****
Intentional Updates for Streaming Reinforcement Learning
Arsalan Sharifnassab, Mohamed Elsayed, Kris De Asis, A. Rupam Mahmood, Richard S Sutton
In gradient-based learning, a step size chosen in parameter units does not produce a predictable per-step change in function output. This often leads to instability in the streaming setting (i.e., batch size$=1$), where stochasticity is not averaged out and update magnitudes can momentarily become arbitrarily big or small. Instead, we propose intentional updates: first specify the intended outcome of an update and then solve for the step size that approximately achieves it. This strategy has precedent in online supervised linear regression via Normalized Least Mean Squares (NLMS) algorithm, which selects a step size to yield a specified change in the function output proportional to the current error. We extend this principle to streaming deep reinforcement learning by defining appropriate intended outcomes: Intentional TD aims for a fixed fractional reduction of the TD error, and Intentional Policy Gradient aims for a bounded per-step change in the policy, limiting local KL divergence. We propose practical algorithms combining eligibility traces and diagonal scaling. Empirically, these methods yield state-of-the-art streaming performance, frequently performing on par with batch and replay-buffer approaches.
****
Subliminal Effects in Your Data: A General Mechanism via Log-Linearity
Ishaq Aden-Ali, Noah Golowich, Allen Liu, Abhishek Shetty, Ankur Moitra, Nika Haghtalab
Training modern large language models (LLMs) has become a veritable smorgasbord of algorithms and datasets designed to elicit particular behaviors, making it critical to develop techniques to understand the effects of datasets on the model's properties. This is exacerbated by recent experiments that show datasets can transmit signals that are not directly observable from individual datapoints (Halawi et al., 2024; Betley et al., 2025b;Cloud et al., 2025; Betley et al., 2025a), posing a conceptual challenge for dataset-centric understandings of LLM training and suggesting a missing fundamental account of such phenomena. Towards understanding such effects, inspired by recent work on the linear structure of LLMs (Park et al., 2024; Golowich et al., 2025b), we uncover a general mechanism through which hidden subtexts can arise in generic datasets.

We introduce LOGIT-LINEAR SELECTION (LLS), a method that prescribes how to select subsets of a generic preference dataset to elicit a wide range of hidden effec

ts. We apply LLS to discover subsets of real-world datasets so that models train ed on them exhibit behaviors ranging from having specific preferences, to respon ding to prompts in a different language not present in the dataset, to taking on a different persona. Crucially, the effect persists for the selected subset, ac ross models with varying architectures, supporting its generality and universali ty.

TideGS: Scalable Training of Over One Billion 3D Gaussian Splatting Primitives v ia Out-of-Core Optimization
Chonghao Zhong, Linfeng Shi, Chen Hua, Tiecheng Sun, Hao Zhao, Binhang Yuan, Cha ojian Li
Training 3D Gaussian Splatting (3DGS) at billion-primitive scale is fundamentall y memory-bound: each Gaussian primitive carries a large attribute vector, and th e aggregate parameter table quickly exceeds GPU capacity, limiting prior systems to tens of millions of Gaussians on commodity single-GPU hardware. We observe t hat 3DGS training is inherently sparse and trajectory-conditioned: each iteratio n activates only the Gaussians visible from the current camera batch, so GPU mem ory can serve as a working-set cache rather than a persistent parameter store. B uilding on this insight, we introduce TideGS, an out-of-core training framework that manages parameters across an SSD-CPU-GPU hierarchy via three synergistic te chniques: block-virtualized geometry for SSD-aligned spatial locality, a hierarc hical asynchronous pipeline to overlap I/O with computation, and trajectory-adap tive differential streaming that transfers only incremental working-set deltas b etween iterations. Experiments show that TideGS enables training with over one b illion Gaussians on a single 24-GB GPU while achieving the best reconstruction q uality among evaluated single-GPU baselines on large-scale scenes, scaling beyon d prior out-of-core baselines (e.g., ~100M Gaussians) and standard in-memory tra ining (e.g., ~11M Gaussians). Project page: https://sponge-lab.github.io/TideGS/

Reduction of Probabilistic Chemical Reaction Networks
Mauricio Montes, Grégoire Sergeant-Perthuis
Programming adaptive behaviors at the cellular level is a long-standing goal tha t raises the question of how probabilistic computation can be implemented in bio chemical systems. Chemical reaction networks (CRNs) provide such a substrate and have been shown to realize probabilistic models, including hidden Markov models and factor graphs, with dynamics reproducing Bayesian inference and belief prop agation. However, encoding these algorithms typically requires prohibitively lar ge reaction networks, and classical CRN reduction techniques do not directly app ly. By recovering the factor graph structure encoded in Napp--Adams-compiled CRN s, we transport recent factor-graph reduction results to their chemical implemen tations, obtaining significantly smaller CRNs while preserving the belief-propagation fixed points on surviving variables.

The Power of Power Law: Asymmetry Enables Compositional Reasoning
Zixuan Wang, Xingyu Dang, Jason D. Lee, Kaifeng Lyu
Natural language data follows a power-law distribution, with most knowledge and skills appearing at very low frequency. While a common intuition suggests that r eweighting or curating data toward a uniform distribution may help models better learn these long-tail skills, we find a counterintuitive result: across a wide range of compositional reasoning tasks, such as state tracking and multi-step ar ithmetic, training under power-law distributions consistently outperforms traini ng under uniform distributions. To understand this advantage, we introduce a min imalist skill-composition task and show that learning under a power-law distribu tion provably requires significantly less training data. Our theoretical analysi s reveals that power law sampling induces a beneficial asymmetry that improves t he pathological loss landscape, which enables models to first acquire high-frequ ency skill compositions with low data complexity, which in turn serves as a step ping stone to efficiently learn rare long-tailed skills. Our results offer an al ternative perspective on what constitutes an effective data distribution for tra ining models.

****
Meta Flow Maps enable scalable reward alignment
Peter Potaptchik, Adhi Saravanan, Abbas Mammadov, Alvaro Prat, Michael Samuel Albergo, Yee Whye Teh
Controlling generative models—whether via inference-time steering or fine-tuning—is expensive. Control relies on estimating the value function—typically necessitating costly trajectory simulations. To eliminate this bottleneck, we introduce *Meta Flow Maps (MFMs)*, stochastic extensions of consistency models and flow maps. MFMs are trained to perform \textbf{one-step posterior sampling}, generating arbitrarily many i.i.d. draws of clean data x_1 from any noisy state x_t. Crucially, these samples are differentiable in the conditioning state x_t, unlocking efficient estimation of the value function gradient. We leverage this capability to enable both **inference-time steering** without inner rollouts, and unbiased, off-policy **fine-tuning** to general rewards. Among our fine-tuning and steering experiments on ImageNet, we highlight that our single-particle steered-MFM sampler outperforms a Best-of-1000 baseline across multiple rewards at a fraction of the compute.
****
Token Sample Complexity of Attention
Léa Bohbot, Cyril Letrouit, Gabriel Peyré, François-Xavier Vialard
As context windows in large language models continue to expand, it is essential to characterize how attention behaves at extreme sequence lengths. We introduce token sample complexity: the rate at which attention computed on n tokens converges to its infinite-token limit. We estimate finite-n convergence bounds at two levels: pointwise uniform convergence of the attention map, and convergence of moments for the transformed token distribution.

For compactly supported (and more generally sub-Gaussian) distributions, our first result shows that the attention map converges uniformly on a ball of radius R at rate $C(R)/\sqrt{n}$, where $C(R)$ grows exponentially with R. For large R, this estimate loses practical value, and our second result addresses this issue by establishing convergence rates for the moments of the transformed distribution (the token output of the attention layer). In this case, the rate is $C'(R)/n^{\beta}$ with $\beta<\tfrac{1}{2}$, and $C'(R)$ depends polynomially on the size of the support of the distribution. The exponent β depends on the attention geometry and the spectral properties of the token distribution. We also examine the regime in which the attention parameter tends to infinity and the softmax approaches a hardmax, and in this setting, we establish a logarithmic rate of convergence. Experiments on synthetic and real data support our predictions and show that the predicted slowdown is reflected in downstream accuracy.

EVMbench: Evaluating AI Agents on Smart Contract Security
Justin Wang, Andreas Bigger, Xiaohai Xu, Justin W Lin, Andy Applebaum, Tejal Patwardhan, Alpin Yukseloglu, Olivia Watkins
Smart contracts on public blockchains now manage large amounts of value, and vulnerabilities in these systems can lead to substantial losses. As AI agents become more capable at reading, writing, and running code, it is natural to ask how well they can already navigate this landscape, both in ways that improve security and in ways that might increase risk.
We introduce EVMbench, an evaluation that measures the ability of agents to detect, patch, and exploit smart contract vulnerabilities.
EVMbench draws on 117 curated vulnerabilities from 40 repositories and, in the most realistic setting, uses programmatic grading based on tests and blockchain state under a local Ethereum execution environment.
We evaluate a range of frontier agents and find that they are capable of discovering and exploiting vulnerabilities end-to-end against live blockchain instances.
We release code, tasks, and tooling to support continued measurement of these capabilities and future work on security.

One-Step Graph-Structured Neural Flows for Irregular Multivariate Time Series C

lassification
Mengzhou Gao, kaiwei wang, Pengfei Jiao
Neural Flows efficiently model irregular multivariate time series by directly le
arning ODE solution trajectories with neural networks, bypassing step-by-step nu
merical solvers. Despite their efficiency, many existing approaches treat variab
les independently, leaving inter-variable interactions underexplored. Moreover,
their one-step mapping makes interaction modeling inherently challenging, as it
removes the iterative refinement of interactions during learning. To address thi
s challenge, we propose one-step Graph-Structured Neural Flows (GSNF), which int
roduce two auxiliary-trajectory self-supervision strategies to strengthen intera
ction learning: (i) interaction-aware trajectory generation via re-initializatio
n, which induces trajectory divergence to expose graph-induced interactions, wit
h a theoretically derived lower bound on divergence; and (ii) reverse-time traje
ctory generation, which enforces forward–backward consistency to regularize grap
h learning, enabled by flow invertibility. Experiments on five real-world datase
ts show that GSNF achieves state-of-the-art classification performance with high
ly competitive training time and memory usage. The code is available at https://
github.com/mzgaooo/GSNF.

GIST: Targeted Data Selection for Instruction Tuning via Coupled Optimization Ge
ometry
Guanghui Min, Tianhao Huang, Ke Wan, Chen Chen
Targeted data selection has emerged as a crucial paradigm for efficient instruct
ion tuning, aiming to identify a small yet influential subset of training exampl
es for a specific target task.
In practice, influence is often measured through the effect of an example on par
ameter updates.
To make selection scalable, many approaches leverage optimizer statistics (e.g.,
 Adam states) as an axis-aligned surrogate for update geometry (i.e., diagonal p
recondition), implicitly treating parameters as coordinate-wise independent.
We show that this assumption breaks down in parameter-efficient fine-tuning (PEF
T) methods such as LoRA. In this setting, the induced optimization geometry exhi
bits strong cross-parameter coupling with non-trivial off-diagonal interactions,
 while the task-relevant update directions are confined to a low-dimensional sub
space.
Motivated by this mismatch, we propose **GIST** (Gradient Isometric Subspace Tra
nsformation), a simple yet principled alternative that replaces axis-aligned sca
ling with robust subspace alignment.
GIST recovers a task-specific subspace from validation gradients via singula
r value decomposition (SVD), projects training gradients into this coupled subsp
ace, and scores examples by their alignment with target directions.
Extensive experiments have demonstrated that **GIST** matches or outperforms the
 state-of-the-art baseline with only 0.29% of the storage and 25% of the computa
tional time under the same selection budget.

Strategic Candidacy in Generative AI Arenas
Chris Hays, Rachel Li, Bailey Flanigan, Manish Raghavan
AI arenas, which rank generative models from pairwise preferences of users, are
a popular method for measuring the relative performance of models in the course
of their organic use. Because rankings are computed from noisy preferences, ther
e is a concern that model producers can exploit this randomness by submitting ma
ny models (e.g., multiple variants of essentially the same model) and thereby ar
tificially improve the rank of their top models. This can lead to degradations i
n the quality, and therefore the usefulness, of the ranking. In this paper, we b
egin by establishing, both theoretically and in simulations calibrated to data f
rom the platform Arena (formerly LMArena, Chatbot Arena), conditions under which
 producers can benefit from submitting clones when their goal is to be ranked hi
ghly. We then propose a new mechanism for ranking models from pairwise compariso
ns, called You-Rank-We-Rank (YRWR). It requires that producers submit rankings o
ver their own models and uses these rankings to correct statistical estimates of

model quality. We prove that this mecha-nism is approximately clone-robust, in the sense that a producer cannot improve their rank much by doing anything other than submitting each of their unique models exactly once. Moreover, to the extent that model producers are able to correctly rank their own models, YRWR improves overall ranking accuracy. In further simulations, we show that indeed the mechanism is approximately clone-robust and quantify improvements to ranking accuracy, even under producer mis-ranking.

Loss-Aware Distributionally Robust Optimization via Trainable Optimal Transport Ambiguity Sets
Jonas Ohnemus, Marta Fochesato, Riccardo Zuliani, John Lygeros
Optimal-transport distributionally robust optimization (OT-DRO) robustifies data-driven decision-making under uncertainty by capturing the sampling-induced statistical error via optimal transport ambiguity sets. The standard OT-DRO pipeline consists of a two-step procedure, where the ambiguity set is first designed and subsequently embedded into the downstream OT-DRO problem. However, this separation between uncertainty quantification and optimization may lead to excessive conservatism. We introduce an end-to-end pipeline to automatically learn decision-focused ambiguity sets for OT-DRO problems, where the loss function informs the shape of the ambiguity set, leading to less conservative decisions whose distributional robustness is enforced via data-driven bootstrapping. We formulate the learning problem as a bilevel optimization program and solve it via a hypergradient-based method. By leveraging the recently introduced nonsmooth conservative implicit function theorem, we establish convergence to a critical point of the bilevel problem. We present experiments validating our method on standard portfolio optimization and linear regression tasks.

MAVRL: Learning Reward Functions from Multiple Feedback Types with Amortized Variational Inference
Raphaël Baur, Yannick Metz, Maria Gkoulta, Mennatallah El-Assady, Giorgia Ramponi, Thomas Kleine Buening
Reward learning typically relies on a single feedback type or combines multiple feedback types using manually weighted loss terms. Currently, it remains unclear how to jointly learn reward functions from heterogeneous feedback types such as demonstrations, comparisons, ratings, rankings, and stops that provide qualitatively different signals. We address this challenge by formulating reward learning from multiple feedback types as Bayesian inference over a shared latent reward function, where each feedback type contributes information through an explicit likelihood. We introduce a scalable amortized variational inference approach that learns a shared reward encoder and feedback-specific likelihood decoders and is trained by optimizing a single evidence lower bound. Our approach avoids reducing feedback to a common intermediate representation and eliminates the need for manual loss balancing. Across discrete and continuous-control benchmarks, we show that jointly inferred reward posteriors outperform single-type baselines, exploit complementary information across feedback types, and yield policies that are more robust to environment perturbations. The inferred reward uncertainty further provides interpretable signals for analyzing model confidence and consistency across feedback types.

HARD-KV: Head-Adaptive Regularization for Decoding-time KV Compression
Yuxuan Yang, Feiyang Ren, Bowen Zeng, Dalin Zhang, Jinpeng Chen, Gang Chen, Huan Li
Long-context LLM inference faces a fundamental conflict: head-adaptive compression algorithms (e.g., Top-p nucleus sampling) offer superior accuracy by dynamically fluctuating memory budgets, yet modern inference engines (e.g., vLLM) demand rigid, static memory patterns to leverage CUDA Graphs and PagedAttention.
We resolve this ``Static-Dynamic'' mismatch with HARD-KV, a unified framework that that bridges dynamic selection with rigid system constraints.
HARD-KV introduces a Cascade Cache hierarchy, managing the token lifecycle across dense, sparse, and condensed tiers.

Crucially, we propose a Logits Calibration mechanism that normalizes diverse imp ortance metrics into a unified probability space, enabling consistent Top-p bu dgeting across heterogeneous heads.
To bridge the efficiency gap, we offer a system-level solution, which rewrites f ragmented, dynamic indices into contiguous physical layouts compatible with high -performance inference engine.
Extensive experiments on math-reasoning benchmarks (AIME, U-Math) verify that HA RD-KV achieves up to 2$\times$ throughput improvement over static baselines whil e maintaining high-fidelity generation in 10k+ token scenarios.
Code is available at https://github.com/SuDIS-ZJU/HARDInfer.

FIRE: Multi-Fidelity Regression with Distribution-Conditioned In-Context Learnin g Using Tabular Foundation Models
Rosen Ting-Ying Yu, Nicholas Sung, Faez Ahmed
Multi-fidelity (MF) regression often operates in regimes of extreme data imbalan ce, where the commonly-used Gaussian-process surrogates struggle with cubic scal ing costs and overfit to sparse high-fidelity observations, limiting efficiency and generalization in real-world applications. We introduce FIRE, a training-fre e MF framework that couples tabular foundation models (TFMs) to perform zero-sho t in-context Bayesian inference via a high-fidelity correction model conditioned on the low-fidelity model's posterior predictive distributions. This cross-fide lity information transfer via distributional summaries captures heteroscedastic errors, enabling robust residual learning without model retraining. Across 31 be nchmark problems spanning synthetic functions and real-world tasks (e.g., DrivAe rNet, LCBench), FIRE delivers a stronger performance–time trade-off than seven s tate-of-the-art GP-based or deep learning MF regression methods, ranking highest in accuracy and uncertainty quantification with runtime advantages. Limitations include context window constraints and dependence on the quality of the pre-tra ined TFMs. Code & data can be found here: https://github.com/rosenyu304/FIRE.

Unsupervised Process-Aware Coreset Selection for In-Context Learning
Wei Zheng, Zijie Wang, Xin Li, Bin Gong, YUQING SUN
We address the challenge of unsupervised coreset selection for few-shot in-conte xt learning (ICL). The goal is to select a small subset of examples under a fixe d annotation budget to yield effective prompts for large language models. Existi ng geometry-based methods often yield coresets that suffer from a skewed distrib ution, due to the oversampling of peripheral examples and high local redundancy. To address these issues, we propose a process-aware framework for coreset selec tion. It jointly optimizes the diversity and representativeness of selected samp les via an adaptive submodular objective. It ensures representativeness by selec ting samples based on local density awareness, while promoting diversity by impo sing a redundancy penalty relative to the evolving selected set. Thus, it perfor ms progress-aware balancing of representativeness and diversity based on the sel ection context. Extensive experiments on 7 NLP datasets demonstrate that our met hod consistently outperforms state-of-the-art coreset selection methods in downs tream ICL performance. Further analysis validates that our approach better balan ces diversity and representativeness in the selection process, while retaining t he theoretical guarantees of adaptive submodular optimization.

Envisioning Beyond the Few: Disentangled Semantics and Primitives for Few-Shot A typical Layout-to-Image Generation
Nan Bao, Yifan Zhao, Wenzhuang Wang, Jia Li
The layout-to-image (L2I) task enables fine-grained control over image generatio n via object categories and spatial layouts. However, existing L2I methods yield fragmented and distorted generations under few-shot atypical settings. We term this failure as representation fragmentation, arising from a granularity mismatc h that entangles semantic identity with visual details. To address this issue, w e propose a representation-driven framework that disentangles semantics from pri mitives for robust few-shot adaptation. Specifically, Semantic Anchoring aggrega tes categorical semantics into anchors for stable identity, while Primitive Imbu

ing models recomposable primitives for robust local detail modeling. Conceptual Steering further regulates optimization with a saliency-aware objective to preserve foreground semantic consistency. Extensive experiments demonstrate consistent improvements in the 5-shot regime over state-of-the-art L2I methods in both visual fidelity and alignment across diverse atypical domains. The source code is publicly available at https://github.com/iCVTEAM/DSP.

IRPM: Intergroup Relative Preference Modeling for Pointwise Generative Reward Models

Haonan Song, Qingchen Xie, Huan Zhu, Feng Xiao, Luxi Xing, Liu Kang, Fuzhen Li, Zhiyong Zheng, Feng Jiang, Ziheng Li, Kun Yan, Qingyi Si, Yanghua Xiao, Hongcheng Guo, Fan Yang

Generative Reward Models (GRMs) have demonstrated strong performance in reward modeling, due to their interpretability and potential for refinement through reinforcement learning (RL). However, widely used pairwise GRMs create a computational bottleneck in reinforcement learning from human feedback (RLHF), when calibrating or aggregating preference signals over n candidates, often incurring $\mathcal{O}(n^2)$ pairwise judgments. To address this issue, we propose **Intergroup Relative Preference Modeling (IRPM)**, an RL-based method that extends the Bradley-Terry preference-learning paradigm via intergroup comparisons to train *pointwise* GRMs from pairwise preference data. IRPM derives a pointwise reward for each response by contrasting groups of chosen vs. rejected samples, enabling pointwise scores comparable across candidate sets and $\mathcal{O}(n)$ reward evaluation for a variable number of candidates during RL training, while preserving interpretability and scalability. Experiments show that IRPM achieves state-of-the-art performance among pointwise GRMs on JudgeBench and RewardBench, and approaches the performance of leading pairwise GRMs. In addition, IRPM achieves substantial gains in post-training evaluations, demonstrating its effectiveness. Our models and code are available at https://github.com/XINGYUN-AI-LAB/IRPM.

Large-capacity and Receiver Authenticable Generative Image Steganography

Jiannian Wang, Yao Lu, Guangming Lu

Diffusion-based generative image steganography converts the input single secret image into noise, and generates the stego image with it serves as the initial noise. Nevertheless, existing methods exhibit three severe limitations: (1) the fixed hiding space constrains their capacity to one secret image; (2) severe inter-secret interference arising from substantial information divergence among multiple secret images while concealing them within a shared hiding space; (3) security risks owing to the absence of the receiver-side verification mechanism. To systematically address these issues, this paper proposes a novel **Receiver Authenticable Generative Image Steganography framework** based on diffusion models. We introduce a **Dynamic Cover Selection and Optimization Engine** to adaptively allocate suitable hiding spaces for different secret images. This design permits the concealment of disparate secret images (or fragments of a single image) into separate spaces, enabling dynamic multi-image concealment while effectively preventing inter-secret interference and expanding capacity through the enlarged hiding spaces. Furthermore, a **Signature Authentication Controller** cryptographically signs the secret container after concealing and verifies it before extraction, ensuring secure receiver isolation and precise localization of the secret data container. Experiments demonstrate that the proposed framework achieves superior secure multi-receiver isolation and high-performance generative image steganography with large capacity.

Instruction Decomposition and Action Alignment for Vision-Language Navigation

Zihao Xin, Wentong Li, Yixuan Jiang, Bin Wang, Piji Li, Jianke Zhu, Jie Qin, Sheng-Jun Huang

Vision-and-Language Navigation (VLN) empowered by Multimodal Large Language Models (MLLMs) is promise, yet remains challenged by long-horizon tasks with complex user instructions. Existing approaches that continuously condition on full instructions incur high latency due to abundant visual tokens and exacerbates instr

uction interference, where irrelevant text noise induces hallucinations.
To address these limitations, we propose IDEAL-VLN (\textbf{I}nstruction \textbf{DE}composition and \textbf{A}ction a\textbf{L}ignment), a novel paradigm that reformulates navigation as a causal inference chain. We decompose the task into two sequential steps: Semantic Anchoring and Action Alignment. We adopt a \textit{Think-Before-Act} mechanism that first infers the immediate semantic anchor from the global context and then generates actions conditioned solely on this anchor. This design constructs an explicit information bottleneck, suppressing spurious correlations from irrelevant instruction. Moreover, to alleviate cognitive collapse and limited exploration during training, we introduce a hierarchical correction framework that combines semantic-level thought correction with a spatially-aware adaptive intervention strategy. This strategy adjusts expert intervention probability based on geodesic distance, effectively defining a semantic safety boundary. To support this paradigm, we contribute the Instruction-Aligned Navigation Dataset containing 160K image-text pairs.
Extensive experiments demonstrate that IDEAL-VLN achieves state-of-the-art performance and robustness across major benchmarks while significantly reducing inference costs.

Continuous-Time Piecewise-Linear Recurrent Neural Networks
Alena Brändle, Lukas Eisenmann, Florian Götz, Daniel Durstewitz
In dynamical systems reconstruction (DSR) we aim to recover the dynamical system (DS) underlying observed time series. Specifically, we aim to learn a generative surrogate model which approximates the underlying, data-generating DS, and recreates its long-term properties (`climate statistics'). In scientific and medical areas, in particular, these models need to be mechanistically tractable -- through their mathematical analysis we would like to obtain insight into the recovered system's workings. Piecewise-linear (PL), ReLU-based RNNs (PLRNNs) have a strong track-record in this regard, representing SOTA DSR models while allowing mathematical insight by virtue of their PL design. However, all current PLRNN variants are *discrete-time maps*. This is in disaccord with the assumed continuous-time nature of most physical and biological processes, and makes it hard to accommodate data arriving at *irregular* temporal intervals. Neural ODEs are one solution, but they do not reach the DSR performance of PLRNNs and often lack their tractability. Here we develop theory for *continuous-time* PLRNNs (cPLRNNs): We present a novel algorithm for training and simulating such models, bypassing numerical integration by efficiently exploiting their PL structure. We further demonstrate how important topological objects like equilibria or limit cycles can be determined semi-analytically in trained models. We compare cPLRNNs to both their discrete-time cousins as well as Neural ODEs on DSR benchmarks, including systems with discontinuities which come with hard thresholds.

The Invisible Lottery: How Subtle Cues Steer Algorithm Choice in LLM Code Generation
Akanksha Narula, Mofasshara Binte Rafique, Laurent Bindschaedler
Large language models (LLMs) now generate substantial production code, often for tasks with multiple valid algorithmic solutions. Incidental prompt cues—contextual words or metadata outside the task specification—can steer which algorithm the model selects, even when all outputs pass the same tests. Prompt sensitivity is well studied as a mechanism for improving output quality; here, we instead study *output policy*: algorithm choice under fixed correctness. We define *algorithm steering* as cue-induced shifts in algorithm-family distributions and run 46,535 controlled experiments across 11 tasks, 19 cue types (18 channels plus a memoization semantic-vs-surface ablation that preserves meaning while changing typography and punctuation), and 15 model configurations. We find large, systematic shifts in algorithm-family distributions (up to 100 percentage points, pp), largely consistent with cue semantics, including in applied tasks such as rate limiting. Direct algorithm naming is the most reliable mitigation we tested. These results reveal an “invisible lottery” in which accidental context alters downstream properties such as performance, security, and maintainability.

SONAR: Spectral■Contrastive Audio Residuals for Generalizable Deepfake Detection
Ido Nitzan Hidekel, Gal Lifshitz, Khen Cohen, Dan Raviv
Deepfake audio detectors often fail to generalize to unseen attacks, in part due to \emph{spectral bias}: neural networks prioritize low-frequency structure while under-exploiting subtle high-frequency (HF) artifacts left by generative models. We introduce \textbf{SONAR} (Spectral-cONtrastive Audio Residuals), a frequency-guided framework that \emph{explicitly enforces representation-level consistency} between semantic content and HF residuals. Unlike prior frequency-aware or dual-stream detectors that treat HF cues as auxiliary features, SONAR encourages structured interaction between content and noise representations in latent space. The model employs a dual-path architecture in which an XLSR encoder captures low-frequency content, while a parallel branch with learnable, value-constrained 1D SRM (Spatial Rich Model) high-pass filters distills HF residuals. The two representations are fused via frequency cross-attention and trained with a \emph{Jensen--Shannon alignment loss} that promotes LF–HF consistency for genuine audio and amplifies inconsistency for deepfakes. Evaluated on ASVspoof~2021 and in-the-wild benchmarks, SONAR achieves state-of-the-art performance in a \textbf{single run} setting and converges faster than strong baselines. By mitigating the effects of spectral bias through frequency-guided alignment, SONAR provides a fully data-driven and architecture-agnostic approach to generalizable audio deepfake detection.
****
Self-Distilled Reasoner: On-Policy Self-Distillation for Large Language Models
Siyan Zhao, Zhihui Xie, Mengchen Liu, Jing Huang, Guan Pang, Feiyu Chen, Aditya Grover
Knowledge distillation improves large language model (LLM) reasoning by compressing the knowledge of a teacher LLM to train smaller LLMs. On-policy distillation advances this approach by having the student sample its own trajectories while a teacher LLM provides dense token-level supervision, addressing the distribution mismatch between training and inference in off-policy distillation methods. However, on-policy distillation typically requires a separate, often larger, teacher LLM and does not explicitly leverage ground-truth solutions available in reasoning datasets. Inspired by the intuition that a sufficiently capable LLM can rationalize external privileged reasoning traces and teach its weaker self, we introduce On-Policy Self-Distillation (OPSD), a learning algorithm where a single LLM acts as both teacher and student with different contexts. The teacher policy conditions on privileged information while the student policy sees only the question; training minimizes the per-token divergence between these distributions over the student's own rollouts. We demonstrate the efficacy of our method on multiple mathematical reasoning benchmarks, achieving superior token efficiency compared to reinforcement learning methods and better performance over off-policy distillation methods.
****
Estimating Tail Risks in Language Model Output Distributions
Rico Angell, Raghav Singhal, Zachary Horvitz, Zhou Yu, Rajesh Ranganath, Kathleen McKeown, He He
Language models are increasingly capable and are being rapidly deployed on a population-level scale. As a result, the safety of these models is increasingly high-stakes. Fortunately, advances in alignment have significantly reduced the likelihood of harmful model outputs. However, when models are queried billions of times in a day, even rare worst-case behaviors will occur. Current safety evaluations focus on capturing the distribution of inputs that yield harmful outputs. These evaluations disregard the probabilistic nature of models and their tail output behavior. To measure this tail risk, we propose a method to efficiently estimate the probability of harmful outputs for any input query. Instead of naive brute-force sampling from the target model, where harmful outputs could be rare, we operationalize importance sampling by creating unsafe versions of the target model. These unsafe versions enable sample-efficient estimation by making harmful outputs more probable. On benchmarks measuring misuse and misalignment, these es

timates match brute-force Monte Carlo estimates using 10–20× fewer samples. For example, we can estimate probability of harmful outputs on the order of $10^{−4}$ with just 500 samples. Additionally, we find that these harmfulness estimates can reveal the sensitivity of models to perturbations in model input and predict deployment risks. Our work demonstrates that rare-event estimation is both critical and feasible for safety evaluations.
****
Can LLM Agents Stick to the Script? Modeling Commitment in Interactive Narratives
Yingpeng Ma, Jianhao Yan, Bei Shi, Ka Hou Kam, Runnan Wang, Xuebo Liu, Yulong Chen, Yue Zhang, Derek F. Wong
The rapid advancement of Large Language Models (LLMs) is revolutionizing AI for Games by enabling open-ended and fluid interactive storytelling.
However, existing research has largely overlooked the critical challenge of maintaining logical consistency and narrative integrity against unconstrained user interventions.
To address this, we formulate this challenge as *Narrative Commitment Preservation (NCP)*, and take interactive narrative as our testbed.
We introduce **NCP-Bench**, a benchmark of 100 narrative environments derived from movie synopses.
Each environment includes a structured narrative specification (trajectory, commitments, and initial facts) that we can automatically check throughout the interaction between the player agent and the narrator agent.
Experiments across state-of-the-art LLMs reveal that high linguistic quality does not guarantee commitment preservation; even strong models frequently generate logically conflicting content under adversarial interventions, with the best-performing model (GPT-5.2) achieving only 40\% survival rate after 20 turns and fact conflict rates ranging from 40\% to 68\% across models.
****
HyMTRL: A Hybrid Multi-Task Reinforcement Learning Framework via Phased Policy Evolution
Jinmin He, Kai Li, Xiaoyi Dong, Yifan Zang, Yuheng Jing, Yifan Zhang, Junliang Xing, Jian Cheng
Multi-task reinforcement learning (MTRL) aims to improve sample efficiency by sharing knowledge across related tasks, but it often suffers from asynchronous convergence speed caused by inherent differences in task difficulty. This imbalance places substantial representational strain on the shared critic network, which emerges as a major performance bottleneck. To address this issue, we propose Hybrid Multi-Task Reinforcement Learning (HyMTRL), a framework that alleviates critic overload through a phased policy evolution strategy. HyMTRL divides task learning into a reinforcement exploration phase and an imitation refinement phase. By transitioning mastered tasks from reinforcement learning–based policy optimization to imitation learning–based behavior consolidation, these tasks are removed from the critic’s optimization objective, effectively reducing representational strain. In addition, a critic reset mechanism restores network capacity while preserving learned policy and historical experience. HyMTRL is a general framework that can be easily integrated with a wide range of existing MTRL methods. Empirical evaluations on the MetaWorld benchmark demonstrate that HyMTRL leads to significant improvements in both learning efficiency and final performance.
****
Provably Data-driven Multiple Hyper-parameter Tuning with Structured Loss Function
TUNG QUOC LE, Anh Tuan Nguyen, Viet Anh Nguyen
Data-driven algorithm design automates hyperparameter tuning, but its statistical foundations remain limited because model performance can depend on hyperparameters in implicit and highly non-smooth ways. Existing guarantees focus on the simple case of a one-dimensional (scalar) hyperparameter. This leaves the practically important, multi-dimensional hyperparameter tuning setting unresolved. We address this open question by establishing the first general framework for establishing generalization guarantees for tuning multi-dimensional hyperparameters in

data-driven settings. Our approach strengthens the generalization guarantee framework for semi-algebraic function classes by exploiting tools from real algebraic geometry, yielding sharper, more broadly applicable guarantees. We then extend the analysis to hyperparameter tuning using the validation loss under minimal assumptions, and derive improved bounds when additional structure is available. Finally, we demonstrate the scope of the framework with new learnability results, including data-driven weighted group lasso and weighted fused lasso.
****
From Representation to Action: A Unified Laplacian Framework for Spatial Representation and Path Planning
Junfeng Zuo, Yuhang He, Wenhao Zhang, Fang Fang, Si Wu
Navigation in complex environments relies on internal spatial representations that guide action. While the brain employs a diverse repertoire of spatial tuning cells—including grid, place, and head-direction cells—a normative theory linking these static neural codes to the dynamic process of navigation remains elusive. In this work, we propose a Unified Laplacian Framework derived from first principles of representational smoothness and efficiency. We first demonstrate that diverse spatial codes emerge naturally as spectral decompositions of the Laplace operator. Crucially, bridging the gap from representation to action, we derive a computational-level navigation policy based on the Green's function potential. We show that this potential encodes the environment's intrinsic geometry to enable geometry-aware gradient ascent, achieving improved sample efficiency and generalization in goal-reaching tasks. Furthermore, we demonstrate that these spectral representations can be learned directly from high-dimensional visual inputs, supporting their learnability from sensory experience. Our results suggest that the ``cognitive map" can be viewed as a spectral embedding of the Laplacian, providing a normative computational account that is biologically consistent with observed spatial-code phenomenology and useful for artificial agents.
****
ReTabSyn: Realistic Tabular Data Synthesis via Reinforcement Learning
Xiaofeng Lin, Seungbae Kim, Zhuoya Li, Zachary DeSoto, Charles Fleming, Guang Cheng
Deep generative models can help with data scarcity and privacy by producing synthetic training data, but they struggle in low-data, imbalanced tabular settings to fully learn the complex data distribution.
We argue that striving for the full joint distribution could be overkill; for greater data efficiency, models should prioritize learning the conditional distribution $P(y\mid \mathbf{X})$, as suggested by recent theoretical analysis.
Therefore, we overcome this limitation with ReTabSyn, a Reinforced Tabular Synthesis pipeline that provides direct feedback on feature correlation preservation during synthesizer training.
This objective encourages the generator to prioritize the most useful predictive signals when training data is limited, thereby strengthening downstream model utility.
We empirically fine-tune a language model-based generator using this approach, and across benchmarks with small sample sizes, class imbalance, and distribution shift, ReTabSyn consistently outperforms state-of-the-art baselines.
Moreover, our approach can be readily extended to control various aspects of synthetic tabular data, such as applying expert-specified constraints on generated observations.
****
CPMöbius: Iterative Coach–Player Reasoning for Data-Free Reinforcement Learning
Ran Li, Zeyuan Liu, Yinghao Chen, Bingxiang He, Jiarui Yuan, Zixuan Fu, Weize Chen, Jinyi Hu, Chen Qian, Zhiyuan Liu, Maosong Sun
Large Language Models (LLMs) have demonstrated strong potential in complex reasoning, yet their progress remains fundamentally constrained by reliance on massive high-quality human-curated tasks and labels, either through supervised fine-tuning (SFT) or reinforcement learning (RL) on reasoning-specific data. This dependence renders supervision-heavy training paradigms increasingly unsustainable, with signs of diminishing scalability already evident in practice. To overcome th

is limitation, we introduce CPMöbius, a collaborative Coach–Player paradigm for data-free reinforcement learning of reasoning models. Unlike traditional adversarial self-play frameworks, CPMöbius inspired by multi-agent collaboration treats the Coach and Player as independent but cooperative roles. The Coach proposes instructions targeted at the Player’s capability and receives rewards based on changes in the Player’s performance, while the Player is rewarded for solving the increasingly instructive tasks generated by the Coach. This cooperative optimization loop is designed to directly enhance the Player’s mathematical reasoning ability. Remarkably, CPMöbius achieves substantial improvement without relying on any external training data, outperforming existing unsupervised approaches. For example, on the Qwen2.5-Math-7B-Instruct, our method improves accuracy by overall average +4.9 and out-of-distribution average +5.4, which exceed RENT for +1.5 on overall accuracy and R-zero for +4.2 on OOD accuracy.

Architecture Matters for Multi-Agent Security

Ben Hagag, William L. Anderson, Christian Schroeder de Witt, Sarah Scheffler

Multi-agent systems (MAS), composed of networks of two or more autonomous AI agents, have become increasingly popular in production deployments, yet introduce security risks that do not arise in single-agent settings. Even if individual agents may exhibit robust security, architectural decisions governing their coordination can create attack surfaces that have not been systematically characterized. In this work, we present an empirical study of how MAS design decisions shape the tradeoff between task performance and attack resistance.

Using a network of web-based agents and stage-wise evaluations that distinguish planning-stage refusal, execution-stage interception, and successful attack completion, we study architectural choices through controlled experiments. We identify three key design choices that influence MAS security: (i) agent roles, which determine how authority and responsibility are allocated; (ii) topology, which shapes how and when agents interact; and (iii) memory, which determines the context and state visibility accessible to each agent. Overall, our results show that security and performance in multi-agent systems are governed by architectural design choices, motivating the development of further evaluations which move beyond the security properties of a single agent.

IPMark: A Sentence-Level Watermark for LLMs with Hierarchical Personalization and Efficient Detection

Wenbo An, Lianwei Wu, Zehao Wang

Watermarking has emerged as a critical solution for the detection and provenance tracing of content generated by large language models. However, existing methods still suffer from significant limitations, including difficulties in achieving efficient and personalized attribution, substantial degradation of generation quality, and low robustness against attacks. To address these challenges, we propose IPMark, the first IP-inspired hierarchical personalized watermarking framework. Specifically, to enable personalization and efficient detection, IPMark employs a hierarchical addressing framework to structurally organize model and user identities. Subsequently, addressing the inherent semantic distortion caused by token-level watermarking, we design a semantic-syntactic dual-stream embedding strategy. Centered on sentence-level candidate selection and reinforced by dual signals from syntactic and semantic features, this approach optimizes the injection process, thereby significantly enhancing generation quality while ensuring strong robustness. Experimental results demonstrate that IPMark achieves the lowest perplexity among baselines, ensuring superior generation quality while maintaining strong robustness and significantly reducing detection latency through hierarchical retrieval. Our code is available at https://github.com/nwlt/IPMark.

CLARITree: Cholesky and Lookahead Accelerations for Regression with Interpretable Piecewise Linear Trees

Yixiao Wang, Hayden McTavish, Varun Babbar, Margo Seltzer, Cynthia Rudin

Regression trees are among the most interpretable yet expressive model classes in machine learning. Historically, greedy induction has been the dominant approac

h for constructing well-performing regression trees. While optimal methods based on dynamic programming and branch-and-bound exist, they are computationally prohibitive for general linear regression trees, despite often achieving substantially better performance than greedy approaches. Recent work has shown that specialized lookahead strategies can dramatically improve runtime while maintaining near-optimal performance, primarily in classification settings. In this work, we develop a novel algorithm for near-optimal, sparse, piecewise linear regression trees that combines a lookahead-style search strategy with efficient rank-one Cholesky updates of the Gram matrix. We demonstrate, both theoretically and empirically, that our method achieves a favorable trade-off between computational efficiency, predictive accuracy, and sparsity, and scales significantly better than the current state of the art.

Mixture of Concept Bottleneck Experts

Francesco De Santis, Gabriele Ciravegna, Giovanni De Felice, Arianna Casanova, Francesco Giannini, Michelangelo Diligenti, Johannes Schneider, Danilo Giordano, Mateo Espinosa Zarlenga, Pietro Barbiero

Concept Bottleneck Models (CBMs) promote interpretability by grounding predictions in human-understandable concepts. However, existing CBMs typically constrain their task predictor to a single expression whose functional form is set a priori, limiting both predictive accuracy and adaptability to diverse user needs. We propose Mixture of Concept Bottleneck Experts (M-CBEs), a framework that generalizes existing CBMs along two dimensions: the number of expressions, referred to as experts, employed by the task predictor to map concepts to the task, and the functional form each expression takes, thus exposing an underexplored region of this design space. We investigate this region by instantiating two novel models: Linear M-CBE, which learns a finite set of linear expressions, and Symbolic M-CBE, which leverages symbolic regression to discover expert functions from data subject to user-specified operator vocabularies. Empirical evaluation demonstrates that varying the number of expressions and their functional form provides a robust framework for navigating the accuracy-interpretability trade-off.

Learning in Bayesian Stackelberg Games With Unknown Follower's Types

Matteo Bollini, Francesco Bacchiocchi, Samuel Coutts, Matteo Castiglioni, Alberto Marchesi

We study online learning in Bayesian Stackelberg games, where a leader repeatedly interacts with a follower whose unknown private type is independently drawn at each round from an unknown probability distribution. The goal is to design algorithms that minimize the leader's regret with respect to always playing an optimal commitment computed with knowledge of the game. We consider, for the first time to the best of our knowledge, the most realistic case in which the leader does not know anything about follower's types, i.e., the possible follower's payoffs. This raises considerable additional challenges compared to the usually addressed case in which follower's payoffs are known. First, we prove a strong negative result: no-regret is unattainable under action feedback, i.e., when the leader only observes the follower's best response at the end of each round. Thus, we focus on the easier type feedback model, where the follower's type is also revealed. In such a setting, we propose an algorithm that achieves a regret of $\widetilde{O}(\sqrt{T})$, ignoring the dependence on other parameters.

PICACO: Pluralistic In-Context Value Alignment via Total Correlation Optimization

Han Jiang, Dongyao Zhu, Xiaoyuan Yi, Ziang Xiao, Zhihua Wei, Xing Xie

In-Context Learning has shown great potential for aligning Large Language Models (LLMs) with human values, helping reduce harmful outputs and accommodate diverse preferences without costly post-training, known as *In-Context Alignment* (ICA).

However, LLMs' comprehension of input prompts remains agnostic, limiting ICA's ability to address value tensions—human values are inherently *pluralistic*, often imposing conflicting demands, *e.g.*, stimulation vs. tradition. Current ICA m

ethods therefore face the *Instruction Bottleneck* challenge, where LLMs struggle to reconcile multiple intended values within a single prompt, leading to incomplete or biased alignment.
To address this, we propose **PICACO**, a novel pluralistic ICA method. Without fine-tuning, PICACO optimizes a meta-instruction that incorporates multiple values to better elicit LLMs' understanding of them and improve alignment. This is achieved by maximizing the total correlation between specified values and LLM responses, which theoretically reinforces value conformity and reduces distractive noise, resulting in more effective instructions. Extensive experiments on five value sets show that PICACO works well with both black-box and open-source LLMs, outperforms several recent strong baselines, and achieves a better balance across up to 8 distinct values.

Keeping a Secret Requires a Good Memory: Unconditional Streaming Lower-Bounds for Differentially Private Algorithms
Alessandro Epasto, Xin Lyu, Pasin Manurangsi
We study the computational cost of differential privacy in terms of memory efficiency. Specifically, we establish for the first time an unconditional space lower bound for user-level differential privacy by introducing a novel proof technique based on a multi-player communication game. We apply our framework, as an example, to the fundamental problem of estimating the number of distinct elements in a stream: we prove that any private algorithm requires almost $\widetilde{\Omega}(T^{1/3})$ space (where T denotes the length of the stream) to achieve certain error rates in a promise variant of the problem, resolving an open problem in the literature (by Jain et al. 2023 and Cummings et al. 2025) and establishes the first exponential separation between the space complexity of private algorithms and their non-private $\widetilde{O}(1)$ counterparts for a natural statistical estimation task. Furthermore, we show that this communication-theoretic technique generalizes to broad classes of problems, yielding lower bounds for private medians, quantiles, and max-select.

Universal Reasoner: A Single, Composable Plug-and-Play Reasoner for Frozen LLMs
Jaemin Kim, Hangeol Chang, Hyunmin Hwang, Choonghan Kim, Jong Chul Ye
Large Language Models (LLMs) have demonstrated remarkable general capabilities, but enhancing skills such as reasoning often demands substantial computational resources and may compromise generalization. While Parameter-Efficient Fine-Tuning (PEFT) methods offer a more resource-conscious alternative, they typically require retraining for each LLM backbone due to architectural dependencies. To address these challenges, we propose Universal Reasoner (UniR)—a lightweight, composable, and plug-and-play reasoning module that can be used with larger frozen LLMs to provide specialized reasoning capabilities. Specifically, UniR decomposes the reward into a standalone reasoning module trained in a decoupled manner using verifiable rewards, effectively translating trajectory-level signals into token-level guidance. Once trained, UniR is combined with frozen LLMs at inference time by simply adding its output logits to those of the backbone. This additive structure enables modular composition: multiple UniR modules trained for different tasks can be jointly applied by summing their logits, enabling complex reasoning via composition. Furthermore, UniR demonstrates weak-to-strong generalization, where reasoning modules trained on smaller models effectively guide much larger LLMs in the same model family, and generalize across domains such as in vision language models and medical reasoning.
Experiments on mathematical reasoning and machine translation show that UniR surpasses existing fine-tuning methods. Code is open-sourced at https://github.com/hangeol/UniR.

NonZero: Interaction-Guided Exploration for Multi-Agent Monte Carlo Tree Search
Sizhe Tang, Zuyuan Zhang, Mahdi Imani, Tian Lan
Monte Carlo Tree Search (MCTS) scales poorly in cooperative multi-agent domains because expansion must consider an exponentially large set of joint actions, severely limiting exploration under realistic search budgets. We propose \textsc{No

nZero}, which keeps multi-agent MCTS tractable by running surrogate-guided selec
tion over a low-dimensional nonlinear representation using an interaction-guided
 proposal rule, instead of directly exploring the full joint-action space. Our e
xploration uses an interaction score: single-agent deviations are ranked by pred
icted gain, while two-agent deviations are scored by a mixed-difference measure
that reveals coordination benefits even when no single agent can improve alone.
We formalize candidate proposal as a bandit problem over local deviations and de
rive a proposal rule, \textsc{NonUCT}, with a sublinear local-regret guarantee f
or reaching approximate graph-local optima without enumerating the joint-action
space. Empirically, \textsc{NonZero} improves sample efficiency and final perfor
mance on MatGame, SMAC, and SMACv2 relative to strong model-based and model-free
 baselines under matched search budgets.

DyPE: Dynamic Position Extrapolation for Ultra High Resolution Diffusion
Noam Issachar, Guy Yariv, Sagie Benaim, Yossi Adi, Dani Lischinski, Raanan Fatta
l
Diffusion Transformer models can generate images with remarkable fidelity and de
tail, yet training them at ultra-high resolutions remains extremely costly due t
o the self-attention mechanism's quadratic scaling with the number of image toke
ns. In this paper, we introduce Dynamic Position Extrapolation (DyPE), a novel,
training-free method that enables pre-trained diffusion transformers to synthesi
ze images at resolutions far beyond their training data, with no additional samp
ling cost. DyPE takes advantage of the spectral progression inherent to the diff
usion process, where low-frequency structures converge early, while high-frequen
cies take more steps to resolve. Specifically, DyPE dynamically adjusts the mode
l's positional encoding at each diffusion step, matching their frequency spectru
m with the current stage of the generative process. This approach allows us to g
enerate images at resolutions that exceed the training resolution dramatically,
e.g., 16 million pixels using FLUX. On multiple benchmarks, DyPE consistently im
proves performance and achieves state-of-the-art fidelity in ultra-high-resoluti
on image generation, with gains becoming even more pronounced at higher resoluti
ons.

Correct Looks Better: Pairwise Comparisons Reveal Accuracy Rankings
Mina Remeli, Moritz Hardt
Pairwise comparisons combined with aggregation methods like Elo have become cent
ral to evaluating generative models, yet concerns remain that they reward superf
icial stylistic cues or display judge biases.
In a more positive turn, we show that model rankings from pairwise comparisons s
trongly agree with ground-truth-based accuracy rankings when such ground truth i
s available for comparison.
By converting five well-known benchmarks into free-form generative evaluations,
we find that Elo rankings achieve a Spearman correlation above 0.9 with accuracy
 rankings and substantially outperform direct evaluation when the judge is weak.

Furthermore, style and judge bias have only minor effects on model rankings, des
pite most judgments occurring on pairs where both candidate answers are correct
(or incorrect).
On such pairs, we find that repetition after the final answer (*echo*) is a caus
al driver of judge preference.

Selective Coupling of Decoupled Informative Regions: Masked Attention Alignment
for Data-Free Quantization of Vision Transformers
Biao Qian, Yang Wang, Yong Wu, Jungong Han
Data-Free Quantization (DFQ) addresses data security concerns by synthesizing sa
mples, without accessing real data. It has garnered increasing attention in the
context of Vision Transformers (ViTs), owing to the superiority of the self-atte
ntion mechanism compared to classical convolutional operation. However, previous
 DFQ arts for ViTs often suffer from a distribution mismatch between synthetic s
amples and input distribution expected by quantized models Q, resulting in the

suboptimal performance. In this paper, we propose a novel Masked Attention Alignment approach for Data-Free Quantization of ViTs, named MaskAQ, revealing that: 1) the semantics in the self-attention mechanism is predominantly localized to a sparse subset of patches, called informative regions; 2) the informative regions dominate the mutual information between synthetic samples and Q's outputs. To these ends, we incorporate differential entropy maximum over patch similarity of synthetic samples, to decouple informative regions from noisy background. To couple with varied Q, the informative regions are selected to align full-precision models with Q via a masked attention alignment objective, thus yielding high-quality synthetic samples.
Furthermore, a periodic sample refreshing strategy comes up to endow MaskAQ with the capacity to continually adapt to the evolving state of Q throughout the training process, to preserve desirable mutual information with synthetic samples.
Extensive experiments verify the merits of MaskAQ over state-of-the-art approaches across multiple backbones and downstream tasks.
Our code is available at https://github.com/hfutqian/MaskAQ.

SPR: A Structured Prompt Refinement Network for Modality Missing
Hao Chen, Diwei Su, Zhuo Wang, Zuwang He, Menglu Chen, Xiuxing Li, Xia Wu
Prompt learning has recently emerged as a dominant paradigm to tackle the missing modalities challenge. However, existing methods often overlook the internal structural information of prompt vectors, limiting performance in guiding frozen backbone models under diverse missing modality scenarios. To address this, we propose a Structured Prompt Refining (SPR) network that refines the internal structure of prompt vectors across multiple dimensions: (1) a Global Interaction Fusion Module captures bidirectional interactions across prompt layers, thereby mitigating sub-optimal adaptation from inconsistent guidance under missing modalities, (2) a Local Feature Refinement Module structures adjacent prompt vectors into coherent semantic units, leveraging local contextual relationships to maintain semantic integrity during modality absence, and (3) a Channel Feature Selection Module uses point-wise gating to adaptively suppress noise and enhance critical channels based on the specific missing modality. Using only 0.8% trainable parameters, SPR achieves significant improvements on three mainstream multimodal classification datasets. Notably, it surpasses state-of-the-art by 3.8% in F1-Macro on the MM-IMDB dataset, even at a 90% modality missing rate. Extensive experiments and in-depth ablations validate SPR's effectiveness and robustness under various missing conditions.

Dissect and Prune: Enhancing Robustness in AI-Generated Image Detection
Dahye Kim, Jaehyun Choi, Hyun Seok Seong, Seongho Kim, Donghun Lee, Sungwon Yi, Jang-Ho Choi
While existing AI-generated image detectors report high performance, we identify that this is largely driven by a critical *prediction asymmetry*: a bias toward the real class that severely limits sensitivity to generated content, especially under standard post-processing operations such as compression and resizing. We hypothesize that this stems from the model's reliance on spurious features, distracting signals that obscure true generative artifacts. To address this, we propose DEAR (Dissect and Prune), which leverages inpainted images to identify and prune these interfering components. Specifically, we find that features strongly aligned to either inpainted or non-inpainted regions are less robust to post-processing. By measuring the alignment between channel activations and inpaint masks, DEAR removes features at both extremes, retaining only those that capture genuine generative artifacts. Experimental results demonstrate that our approach significantly enhances robustness against unseen generators and post-processing, effectively mitigating the prediction asymmetry. Our code is available at https://github.com/dahyedahye/dear.

Non-Stationary Online Structured Prediction with Surrogate Losses
Shinsaku Sakaue, Han Bao, Yuzhou Cao

Online structured prediction, including online classification as a special case, is the task of sequentially predicting labels from input features. In this setting, the *surrogate regret*—the cumulative excess of the actual target loss (e.g., the 0-1 loss) over the surrogate loss (e.g., the logistic loss) incurred by the best fixed estimator—has gained attention because it admits a finite bound independent of the time horizon T. However, such guarantees break down in *non-stationary* environments, where every fixed estimator may incur surrogate loss that grows linearly with T. To address this limitation, we obtain an upper bound of $F_T+O(1+P_T)$ on the cumulative target loss, where F_T is the cumulative surrogate loss of any comparator sequence and P_T is its *path length*. This bound depends on T only through F_T and P_T, thus offering stronger guarantees under non-stationarity. Our core idea is to combine the dynamic regret analysis of online gradient descent (OGD) with the *exploit-the-surrogate-gap* technique. This viewpoint sheds light on the usefulness of a Polyak-style learning rate for OGD, which systematically yields target-loss bounds and performs well empirically. We then extend our approach to broader settings beyond prior work via the *convolutional Fenchel–Young loss*. Finally, a lower bound shows that the dependence on F_T and P_T is tight.

Decomposed On-Policy Distillation for Vision-Language Reasoning: Steering Gradients for Visual Grounding

Hee Suk Yoon, Eunseop Yoon, Jaehyun Jang, SooHwan Eom, Ji Woo Hong, Mark A. Hasegawa-Johnson, Qi Dai, Chong Luo, Chang D. Yoo

While on-policy distillation offers dense supervision for training small reasoning models, its optimization dynamics in the multimodal domain remain under-explored. In this work, we challenge the standard monolithic view of Vision-Language Model (VLM) distillation by mathematically decomposing the loss into two distinct components: the language prior and visual grounding. Our analysis uncovers that gradient vectors for these components are nearly orthogonal, indicating that the objective of aligning with the teacher's language distribution is geometrically independent from the objective of matching its visual perception. Consequently, standard optimization passively follows a suboptimal compromise trajectory that implicitly balances the two objectives. Hypothesizing that visual grounding constitutes the primary bottleneck for vision-language reasoning, we introduce Visual Gradient Steering (VGS), a method that dynamically reorients the update vector to prioritize the visual subspace. Experimental results on multiple distillation settings and complex multimodal benchmarks demonstrate that VGS significantly outperforms the standard monolithic formulation of on-policy distillation, achieving superior grounding with minimal training overhead.

Dynamic TMoE: A Drift-Aware Dynamic Mixture of Experts Framework for Non-Stationary Time Series Forecasting

Jiawen Zhu, Shuhan Liu, Di Weng, Yingcai Wu

Non-stationary time series forecasting is challenged by evolving distribution shifts that static models struggle to capture. While Mixture-of-Experts (MoE) architectures offer a promising paradigm for decoupling complex drift patterns, existing approaches are limited by fixed expert pools and memoryless routing, hampering their ability to adapt to abrupt regime shifts. To address this, we propose **Dynamic TMoE**, a framework that unifies architectural evolution with temporal continuity during learning phase. By detecting distribution shifts via Maximum Mean Discrepancy (MMD), we dynamically instantiate heterogeneous experts and prune redundant ones to optimize capacity. Additionally, a temporal memory router leverages recurrent states and an anomaly repository to ensure stable, context-aware expert selection without requiring test-time updates. Experiments on nine benchmarks demonstrate state-of-the-art performance, reducing MSE by 10.4\% and MAE by 7.8\%. Code is available at https://github.com/andone-07/Dynamic-TMoE.

Two-dimensional quantization for geometry-aware audio coding

Tal Shuster, Eliya Nachmani

Recent neural audio codecs have achieved impressive reconstruction quality, typi

cally relying on quantization methods such as Residual Vector Quantization (RVQ) , Vector Quantization (VQ) and Finite Scalar Quantization (FSQ). However, these quantization techniques limit the geometric structure of the latent space, make it harder to capture correlations between features leading to inefficiency in re presentation learning, codebook utilization and token rate. In this paper we int roduce Two-Dimensional Quantization (Q2D2), a quantization scheme in which featu re pairs are projected onto structured 2D grids, such as hexagonal, rhombic, or rectangular tiling and quantized to the nearest grid values, yielding an implici t codebook defined by the product of grid levels, with codebook sizes comparable to conventional methods. Despite its simple geometric formulation, Q2D2 improve s audio compression efficiency, with low token rates and high codebook utilizati on while maintaining state of the art reconstruction quality. Specifically, Q2D2 achieves competitive to superior performance in various objective and subjectiv e reconstruction metrics, across extensive experiments in speech, audio and musi c domains compared to state of the art models. Comprehensive ablation studies fu rther confirm the effectiveness of our design choices.

Optimal Bayesian Stopping for Efficient Inference of Consistent LLM Answers
Jingkai Huang, Will Ma, Zhengyuan Zhou
A simple strategy for improving LLM accuracy, especially in math and reasoning p roblems, is to sample multiple responses and submit the answer most consistently reached. In this paper we leverage Bayesian prior information to save on sampli ng costs, stopping once sufficient consistency is reached. Although the exact po sterior is computationally intractable, we further introduce an efficient ``L- aggregated'' stopping policy that tracks only the $L-1$ most frequent answer cou nts. Theoretically, we prove that $L=3$ is all you need: this coarse approximati on is sufficient to achieve asymptotic optimality, and strictly dominates prior- free baselines, while having a fast posterior computation. Empirically, this ide ntifies the most consistent (i.e., mode) LLM answer and achieves similar answer accuracy using fewer samples.

Scaling Laws and Architectural Frontiers in Metagenomic Foundation Models
Geraldene Munsamy, Gavin Ayres, Jérémie DONA, Carla Greco, Daniel Anderson, Srij ani Sridhar, William Chow, Aaron W Kollasch, Robert J. Pecoraro, Tanggis Bohnuud , Keith Kam, Gus Minto-Cowcher, Marcus H Y Leung, Hassan Sirelkhatim, John St. J ohn, Ali Taghibakhshi, Tyler C. Shimko, Jared Wilber, Timur Rvachov, Saee Gopal Paliwal, Eduardo Calleja, Noelia Ferruz, Kevin K Yang, Philipp Lorenz, Francesco Farina
Foundation models for genomics have the potential to revolutionize therapeutic d esign, yet the optimal architectural choices for modeling
the vast and diverse distribution of metagenomic data remain under-explored. In this work, we present the machine learning methodology behind EDEN, a family of metagenomic foundation models scaled up to 28 billion parameters and trained on

9.7 trillion nucleotide tokens. We provide a systematic empirical study of architectural trade-offs between autoregressive Transformers (Llama-style), State-Space Models (Mamba), and Long-convolutional architectures (Hyena) for nucleotide-level modeling. Contrary to recent trends favoring linear-time sequence models for long-range biological data, we demonstrate that the Llama architecture exhibits superior scaling efficiency and semantic retrieval capabilities as the model capacity grows. We derive a set of quality-aware scaling laws for metagenomics, showing how model performance follows predictable power-law behavior across three orders of magnitude in parameters and data. Through extensive benchmarking, spanning unsupervised zeroshot fitness prediction, semantic completion, and gene recovery, we establish a blueprint for scaling biological foundation models and provide empirical evidence demonstrating why Transformer-based architectures define the current frontier.
****

Adaptive Momentum and Nonlinear Damping for Neural Network Training
Aikaterini Karoni, Rajit Rajpal, Benedict J. Leimkuhler, Gabriel Stoltz
Momentum Stochastic Gradient Descent (mSGD) relies on a fixed momentum coefficient shared across all parameters, failing to account for the heterogeneous structure of modern loss landscapes. In this work, we adopt a continuous-time formulation to introduce individual, adaptive momentum coefficients regulated by the kinetic energy of each model parameter. This mechanism automatically adjusts to evolving training dynamics to maintain stability without sacrificing convergence speed. We demonstrate that this adaptive friction is inextricably linked to cubic damping, a suppression mechanism from structural dynamics. We additionally introduce two optimization schemes by augmenting the continuous dynamics of mSGD and Adam with a cubic damping term. Empirically, our methods demonstrate robustness and match or outperform Adam on training ViT, BERT, and GPT2 tasks where mSGD typically struggles. We further provide theoretical results establishing the exponential convergence of the proposed schemes.
****

Rank-Aware Spectral Bounds on Attention Logits for Stable Low-Precision Training
Seyed Morteza Emadi
Attention scores in transformers are bilinear forms $S_{ij} = x_i^\top M x_j / \sqrt{d_h}$ whose maximum magnitude governs overflow risk in low-precision training. We derive a \emph{rank-aware concentration inequality}: when the interaction matrix $M = W^Q W^{K\top}$ has rank $r \ll d$, tail probabilities for $\max_{i,j}|S_{ij}|$ decay as $\exp(-d^{2}\alpha^{2}/(\gamma r))$ rather than $\exp(-d\alpha^{2})$, where $\gamma > 1$. For transformer attention where $r = d_h$, this yields 8--$28\times$ tighter concentration than rank-agnostic bounds in modern architectures. We apply this result to FP8 training, deriving \emph{geometry-aware scale factors} that provide principled overflow guarantees without observing activations. The method computes per-layer scales from the spectral norm $\|W^Q W^{K\top}\|_2$ via implicit power iteration, includes a grouped query attention formulation that avoids key expansion, and remains compatible with fused attention kernels. Across GPT-2 XL to Llama-2-70B, geometry-aware scaling eliminates overflows in transient scenarios where delayed scaling fails, while achieving comparable downstream MMLU accuracy.
****

Tailoring Strictly Proper Scoring Rules for Downstream Tasks: An Application to Causal Inference
Roman Plaud, Alexandre Perez-Lebel, Antoine Saillenfest, Thomas Bonald, Marine Le Morvan, Gaël Varoquaux, Matthieu Labeau
Probabilistic models are typically trained using task-agnostic objectives like log-loss, which can lead to significant errors in downstream estimation. This disconnect is especially critical in Inverse Probability Weighting (IPW) for causal inference, where propensity score errors near 0 and 1 often lead to high bias and variance. We propose a principled framework for deriving task-specific strictly proper scoring rules by matching the local curvature of the downstream error metric. We apply this to the Average Treatment Effect (ATE) estimation, deriving a closed-form loss and its corresponding canonical probability mapping that

can be readily integrated with any model like a neural network or a gradient boosting algorithm. Extensive evaluations on causal inference benchmarks demonstrate that our tailored objective consistently outperforms standard likelihood-based and covariate-balancing approaches.

****

Platonic Transformers: A Solid Choice For Equivariance

Mohammad Mohaiminul Islam, Rishabh Anand, David R Wessels, Friso de Kruiff, Thijs P. Kuipers, Rex Ying, Clara I. Sánchez, Sharvaree Vadgama, Georg Bökman, Erik J Bekkers

While widespread, Transformers lack inductive biases for geometric symmetries common in science and computer vision. Existing equivariant methods often sacrifice the efficiency and flexibility that make Transformers so effective through complex, computationally intensive designs. We introduce the Platonic Transformer to resolve this trade-off. By defining attention relative to reference frames from the Platonic solid symmetry groups, our method induces a principled weight-sharing scheme. This enables combined equivariance to continuous translations and Platonic symmetries, while preserving the exact architecture and computational cost of a standard Transformer. Furthermore, we show that this attention is formally equivalent to a dynamic group convolution, which reveals that the model learns adaptive geometric filters and enables a *highly scalable, linear-time convolutional variant*. Across diverse benchmarks in computer vision (CIFAR-10), 3D point clouds (ScanObjectNN), and molecular dynamics, property prediction and generation (OMol25, ProteinMD, QM9), the Platonic Transformer achieves competitive performance by leveraging these geometric constraints at no additional cost.

****

How RL Unlocks the Aha Moment in Geometric Interleaved Reasoning

Xiangxiang Zhang, Caijun Jia, Siyuan Li, he dingyu, Xiya Xiong, Zheng Sun, Honghao He, Yuchen Wu, Bihui Yu, Linzhuang Sun, Cheng Tan, Jingxuan Wei

Solving complex geometric problems inherently requires interleaved reasoning: a tight alternation between constructing diagrams and performing logical deductions. Although recent Multimodal Large Language Models (MLLMs) have demonstrated strong capabilities in visual generation and plotting, we identify a counter-intuitive and underexplored phenomenon. Naively applying Supervised Fine-Tuning (SFT) on interleaved plot–solution data leads to a substantial degradation in reasoning performance compared to text-only baselines. We argue that this failure stems from a fundamental limitation of SFT, which primarily induces distributional alignment: the model learns to reproduce the surface format of interleaved plotting but fails to internalize the causal dependency between the generated plot and reasoning steps. To overcome this limitation, we propose Faire (**F**unctional **a**lignment for **i**nterleaved **re**asoning), a reinforcement learning framework that enforces three casual constraints to move beyond superficial imitation toward functional alignment. Extensive experiments show that Faire induces a qualitative shift in model behavior in which the plotting is effectively internalized, yielding competitive performance on challenging geometric reasoning benchmarks.

PPI Candidate Ranking: Large-Scale Evaluation of a Domain Knowledge–Guided Pipeline

Maria Emilia Russo, Federico Di Valerio, Alessia Borghini, Alessio Ragno, Roberto Capobianco

Computational approaches have become central to Protein–Protein Interaction (PPI) research, complementing experimental techniques that remain costly and incomplete. While modern deep learning methods capture diverse biological signals and hold promise in expanding the known interactome, empirical validation remains a critical bottleneck due to its long and expensive procedures. To address this challenge, we introduce the problem of PPI candidate ranking, aiming to prioritize interactions for experimental testing. We propose a novel framework that leverages domain knowledge through interpretability-guided ranking and further refines prioritization by integrating complementary sources of evidence, including interaction scores, structural plausibility, and biomedical language features. Evalua

tions on a large-scale dataset constructed from successive STRING releases demon strate that our approach yields significant improvements over two state-of-the-a rt PPI prediction models, providing more accurate and biologically coherent rank ings.

SURGE: Approximation and Training Free Particle Filter for Diffusion Surrogate
Lifu Wei, Yinuo Ren, Naichen Shi, Yiping Lu
Data assimilation (DA) tackles the sequential estimation of a dynamical system’s latent state from noisy, partial observations. In this paper, we study DA in a setting where the system dynamics are represented by a pretrained diffusion mode l used as a surrogate forecaster. We focus on how to integrate incoming observat ions into the diffusion surrogate’s predictions to support continuous state corr ection and progressively refining the estimated trajectory over time. After rece iving noisy observations, the diffusion model is guided using the observation li kelihood to steer the generation process toward observation-consistent states. H owever, such guidance does not guarantee sampling from the true posterior. Motiv ated by particle filtering methods, we represent the posterior distribution usin g an ensemble of particles. We perform Sequential Monte Carlo over diffusion tra jectories, working with their path measure. We compute importance weights for ge nerated particles and resample to focus on trajectories consistent with the obse rvations. This procedure corrects the generation dynamics, drives the particle a pproximation toward the desired posterior and leads to an approximation-free par ticle filtering method that rigorously fuses observational data with diffusion m odel simulations.

Principled Synthetic Data Enables the First Scaling Laws for LLMs in Recommendat ion
Benyu Zhang, Qiang Zhang, Jianpeng Cheng, Hong-You Chen, Qifei wang, Wei Sun, Sh en Li, Jia Li, Jiahao Wu, Xiangjun Fan, Hong Yan
Large Language Models (LLMs) represent a promising frontier for recommender syst ems, yet their development has been impeded by the absence of predictable scalin g laws, which are crucial for guiding research and optimizing resource allocatio n. We hypothesize that this may be attributed to the inherent noise, bias, and i ncompleteness of raw user interaction data in prior continual pre-training (CPT) efforts. This paper introduces a novel, layered framework for generating high-q uality synthetic data that circumvents such issues by creating a curated, pedago gical curriculum for the LLM. We provide powerful, direct evidence for the utili ty of our curriculum by showing that standard sequential models trained on our p rincipled synthetic data significantly outperform ($+130\%$ on recall@100 for Sa sRec) models trained on real data in downstream ranking tasks, demonstrating its superiority for learning generalizable user preference patterns. Building on th is, we empirically demonstrate, for the first time, robust power-law scaling for an LLM that is continually pre-trained on our high-quality, recommendation-spec ific data. Our experiments reveal consistent and predictable perplexity reductio n across multiple synthetic data modalities. These findings establish a foundati onal methodology for reliable scaling LLM capabilities in the recommendation dom ain, thereby shifting the research focus from mitigating data deficiencies to le veraging high-quality, structured information.

A Provable Expressiveness Hierarchy in Hybrid Linear-Full Attention
Xiaowei Ye, Xiaoyu He, Chao Liao, Chen Wu, Pinyan Lu
Transformers serve as the foundation of most modern large language models.
To mitigate the quadratic complexity of standard full attention, various efficie nt attention mechanisms, such as linear and hybrid attention, have been develope d.
A fundamental gap remains: their expressive power relative to full attention lac ks a rigorous theoretical characterization.
In this work, we theoretically characterize the performance differences among th ese attention mechanisms.
Our theory applies to all linear attention variants that can be formulated as a

recurrence, including Mamba, DeltaNet, etc.
Specifically, we establish an expressiveness hierarchy: for the sequential function composition-a multi-step reasoning task that must occur within a model's forward pass, an $(L+1)$-layer full attention network is sufficient, whereas any hybrid network interleaving $L-1$ layers of full attention with a substantially larger number (2^{3L^2}) of linear attention layers cannot solve it.
This result demonstrates a clear separation in expressive power between the two types of attention.
Our work provides the first provable separation between hybrid attention and standard full attention, offering a theoretical perspective for understanding the fundamental capabilities and limitations of different attention mechanisms.

Parameter-Masked Decoupled Optimization for Cross-Domain Class-Incremental Learning
Ziqi Gu, Chunyan Xu, Yangguang Liu, Wenxuan Fang, Baotong Su, Tong Zhang, Dan Wang, Zhen Cui
Cross-domain class-incremental learning (CD-CIL) requires models to continuously acquire new classes across shifting domains while retaining previously learned knowledge. Existing approaches often entangle what to update with how to update, resulting in unstable adaptation and severe forgetting under domain shifts.
Inspired by the hippocampal learning mechanism that separates rapid adaptation from stable consolidation, we propose Parameter-Masked Decoupled Optimization (PMDO) that disentangles what knowledge is adapted from how learning proceeds in cross-domain class-incremental learning.
We introduce a domain-aware knowledge decoupler that selectively adapts domain-relevant shared parameters, constraining incremental updates while preserving prior representations.
To regulate how learning proceeds, we further design a stability-aware trajectory regulation that guides optimization along transferable and stable optimization trajectories, thereby reducing interference across domain transitions.
PMDO enables effective cross-domain adaptation while mitigating catastrophic forgetting and maintaining long-term learnability.
Extensive experiments across multiple benchmarks demonstrate the effectiveness of PMDO and its superiority over state-of-the-art methods.
****

Divergence Decoding: Inference-Time Unlearning via Auxiliary Models
Humzah Merchant, Bradford Levy
Large Language Models (LLMs) frequently memorize sensitive training data thereby creating significant privacy and copyright risks. Addressing these risks, i.e., removing such knowledge from an existing model checkpoint, has proven challenging as many unlearning methods lead to catastrophic utility loss or are ineffective for complex queries. We introduce **Divergence Decoding (DD)**, a mechanism that uses small auxiliary models to steer the logits of the LLM away from specific data during inference. Training these models is straight forward, i.e., we use standard pre-training and fine-tuning setups. We find the method decisively outperforms state-of-the-art (SOTA) baselines on unlearning benchmarks across a variety of model and training dataset scales consistent with DD being an effective and inexpensive solution to unlearning. We then demonstrate that this steered distribution can be trivially distilled back into the base model. Since the method is generally applicable to any probabilistic model, we explore its efficacy outside of text generation and find evidence of generalization to the domain of images.
****

Context-free Recognition with Transformers
Selim Jerad, Anej Svete, Sophie Hao, Ryan Cotterell, William Merrill
Transformers excel empirically on tasks that process well-formed inputs according to some grammar, such as natural language and code. However, it remains unclear how they can process grammatical syntax. In fact, under standard complexity conjectures, standard transformers cannot recognize context-free languages (CFLs), a canonical formalism to describe syntax, or even regular languages, a subclass

of CFLs. Past work has shown that $\mathcal{O}(\log(N))$ looping layers (w.r.t. input length N) allow transformers to recognize regular languages, but the question of context-free recognition with looped transformers remained open. In this work, we show that looped transformers with $\mathcal{O}(\log(N))$ looping layers and $\mathcal{O}(N^6)$ padding symbols can recognize all CFLs. However, training and inference with $\mathcal{O}(N^6)$ padding symbols is potentially impractical. Fortunately, we show that, for natural subclasses such as unambiguous CFLs, the recognition problem on transformers becomes more tractable, requiring $\mathcal{O}(N^3)$ padding. Empirically, looped and padded transformers perform better than fixed-depth transformers in recognizing CFLs. Overall, our results shed light on the intricacy of CFL recognition by transformers: while general recognition may require an intractable amount of padding, natural constraints such as unambiguity yield efficient recognition algorithms.

V1: Unifying Generation and Self-Verification for Parallel Reasoners

Harman Singh, Xiuyu Li, Kusha Sareen, Monishwaran Maheswaran, Sijun Tan, Xiaoxia Wu, Junxiong Wang, Alpay Ariyak, Qingyang Wu, Samir Khaki, Rishabh Tiwari, Long Lian, Yucheng Lu, Boyi Li, Alane Suhr, Ben Athiwaratkun, Kurt Keutzer

Test-time scaling for complex reasoning tasks shows that leveraging inference-time compute, by methods such as independently sampling and aggregating multiple solutions, results in significantly better task outcomes. However, a critical bottleneck is *verification*: sampling is only effective if correct solutions can be reliably identified among candidates. While existing approaches typically evaluate candidates independently via scalar scoring, we demonstrate that models are substantially stronger at **pairwise verification**. Leveraging this insight, we introduce **V■**, a framework that unifies generation and verification through efficient pairwise ranking. V■ comprises two components: **V■-Infer**, an uncertainty-guided algorithm using a tournament-based ranking that dynamically allocates self-verification compute to candidate pairs whose relative correctness is most uncertain; and **V■-PairRL**, an RL framework that **jointly trains** a single model as both generator and pairwise self-verifier, ensuring the verifier adapts to the generator's evolving distribution. On competitive code generation, SWE and terminal-based agents, math reasoning, and medical QA benchmarks, V■-Infer improves Pass@1 by up to 10% over pointwise verification and outperforms SoTA aggregation-based test-time scaling while being more efficient. Furthermore, V■-PairRL achieves test-time scaling gains of 3.8–10pp over standard RL and pointwise joint training on code, math, and non-verifiable domains, and improves base Pass@1 by up to 8.7pp over standard RL. [Project page & code](https://harmandotpy.github.io/v1-verification/).

XR-1: Towards Versatile Vision-Language-Action Models via Learning Unified Vision-Motion Representations

Shichao Fan, Kun Wu, Zhengping Che, Xinhua Wang, Di Wu, Fei Liao, Ning Liu, Yixue Zhang, Zhen Zhao, Zhiyuan Xu, Meng Li, Qingjie Liu, Shanghang Zhang, Min Wan, Jian Tang

Recent progress in large-scale robotic datasets and vision-language models (VLMs) has advanced research on vision-language-action (VLA) models. However, existing VLA models still face two fundamental challenges: (\textit{i}) producing precise low-level actions from high-dimensional observations, (\textit{ii}) bridging domain gaps across heterogeneous data sources, including diverse robot embodiments and human demonstrations. Existing methods often encode latent variables from either visual dynamics or robotic actions to guide policy learning, but they fail to fully exploit the complementary multi-modal knowledge present in large-scale, heterogeneous datasets. In this work, we present \textbf{XR-1}, a novel framework for versatile and scalable VLA learning across diverse robots, tasks, and environments.

At its core, XR-1 introduces the \emph{Unified Vision-Motion Codes (UVMC)}, a discrete latent representation learned via a dual-branch VQ-VAE that jointly encodes visual dynamics and robotic motion. UVMC addresses these challenges by (\textit{i}) serving as an intermediate representation between the observations and a

ctions, and (\textit{ii}) aligning multimodal dynamic information from heterogeneous data sources to capture complementary knowledge. To effectively exploit UVMC, we propose a \emph{three-stage training paradigm}: (\textit{i}) self-supervised UVMC learning, (\textit{ii}) UVMC-guided pretraining on large-scale cross-embodiment robotic datasets, and (\textit{iii}) task-specific post-training. We validate XR-1 through extensive real-world experiments with more than 12,000 rollouts on six different robot embodiments, spanning over 120 diverse manipulation tasks. XR-1 consistently outperforms state-of-the-art baselines such as π_0 and GR00T-N1.5 while demonstrating strong generalization to novel objects, background variations, distractors, and illumination changes. Our project is at \href{https://xr-1-vla.github.io/}{https://xr-1-vla.github.io/}.

ConvexBench: Can LLMs Recognize Convex Functions?
Yepeng Liu, Yu Huang, Yu-Xiang Wang, Yingbin Liang, Yuheng Bu
Convexity recognition plays a central role in many optimization, control, and learning problems. However, the ability of Large Language Models (LLMs) to identify this property in symbolic expressions remains unexamined. We introduce ConvexBench, a scalable and mechanically verifiable benchmark for testing whether LLMs can determine the convexity of a symbolic objective under deep functional composition. Experiments on frontier LLMs reveal a sharp \textit{compositional reasoning gap}: performance degrades rapidly with increasing depth, dropping from an F1-score of 1.0 at depth 2 to approximately 0.2 at depth 100. Inspection of models' reasoning traces indicates two failure modes: \textit{parsing failure} and \textit{lazy reasoning}. To address these limitations, we propose an agentic divide-and-conquer framework that (i) offloads parsing to an external tool to construct an abstract syntax tree (AST) and (ii) enforces recursive reasoning over each intermediate sub-expression with focused context. This framework reliably mitigates deep-composition failures, achieving substantial performance improvement at large depths (e.g., F1-Score $= 1.0$ at depth 100).

A Language-Guided Bayesian Optimization for Efficient LoRA Hyperparameter Search
Baek Seong-Eun, Lee Jung-Mok, Kim Sung-Bin, Tae-Hyun Oh
Fine-tuning Large Language Models (LLMs) with Low-Rank Adaptation (LoRA) offers a resource-efficient way to personalize or specialize. However, LoRA is highly sensitive to hyperparameter choices, and exhaustive hyperparameter search is computationally expensive. To address this, we propose a Bayesian Optimization (BO) framework that leverages the domain knowledge of pre-trained LLMs to efficiently search for LoRA hyperparameters. Our approach repurposes a pre-trained LLM as a discrete-to-continuous mapping module to link hyperparameters and their domain knowledge to a continuous vector space, where BO is conducted. We design and control the mapping via language prompting, providing a domain-aware textual prompt that describes the relationships among hyperparameters and their respective roles. This allows us to explicitly inject domain knowledge about LoRA into the LLM in natural language. We also introduce an additional learnable token to capture residual information that is difficult to describe linguistically in the prompt. This aids BO to sample more high-performing hyperparameters. In addition, by leveraging the strong correlation observed between the performance obtained from full and subset training datasets in LoRA training regimes, we introduce proxy training and evaluation using a data subset. This significantly improves the efficiency of our method. We demonstrate that our hyperparameter, discovered with only about 30 iterations, achieves more than 20% performance improvement over standard hyperparameters found from about 45,000 combinations. Project page: https://baekseongeun.github.io/lora-bo/

Cache Coherent Resampling for Efficient Test Time Scaling in LLM Reasoning via Adaptive Sequential Monte Carlo
KE WANG, ZEHAO YU, Luwei Wang, Yongchao Huang
Recent work shows that chain based sampling for power shaped trajectory distributions can deliver large test time gains from a fixed base LLM and can approach RL trained reasoners such as GRPO. Deployment is the bottleneck. Autoregressive M

etropolis Hastings is inherently serial, limits GPU utilization, and exhibits ex treme tail latency at high budgets, reaching p95 $=1318$s on MATH500 at $128\tim es$. We propose Adaptive Sequential Monte Carlo (ASMC), a parallel particle infe rence method that targets power shaped trajectory distributions while adapting p article populations to problem hardness. To make resampling practical for Transf ormers, we introduce cache coherent resampling, which realizes ancestry updates by reordering KV caches and other particle bound tensors, avoiding prefix recomp utation. On MATH500 at the same budget, ASMC attains 80.6\% exact-match accuracy with p95 = 73.7s, substantially reducing the tail latency of sequential MCMC an d providing additional high-accuracy operating points beyond the saturation of b est-of-n. We further analyze particle degeneracy and find that collapse severity , measured by low $\mathrm{ESS}_{\min}/N$, strongly predicts failures, while sen sitivity to the resampling scheme is limited.
****

Generative Augmented Inference
Cheng Lu, Mengxin Wang, Dennis Zhang, Heng Zhang
Large language models enable inexpensive AI-generated annotations, but using the m reliably for causal inference remains challenging. Naively pooling AI and huma n data induces bias, while existing methods such as Prediction-Powered Inference (PPI; Angelopoulos et al., 2023) treat AI outputs as proxies of true labels -- an assumption often violated for generative model outputs in practice. We propos e Generative Augmented Inference (GAI), a framework that treats AI outputs as ge neral, potentially high-dimensional informative features for learning human labe ls rather than as surrogates. GAI flexibly models this relationship using nonpar ametric methods, enabling consistent estimation and valid inference from combine d human and AI data. We establish asymptotic normality and show that, under rand om labeling, GAI strictly improves asymptotic efficiency over human-data-only es timation whenever AI outputs are informative for true labels. Empirical studies on real-world datasets demonstrate that GAI significantly reduces estimation err or and improves confidence interval quality across diverse generative data sourc es relative to human-only and PPI-based estimation.

SIPO: Stabilized and Improved Preference Optimization for Aligning Diffusion Mod els
Xiaomeng Yang, Mengping Yang, Junyan Wang, Zhijian Zhou, Zhiyu Tan, Hao Li
Preference learning has garnered extensive attention as an effective technique f or aligning diffusion models with human preferences in visual generation tasks. However, existing alignment approaches such as Diffusion-DPO suffer from two fun damental challenges: training instability caused by high gradient variances at v arious timesteps and high parameter sensitivities, and off-policy bias arising f rom the discrepancy between the optimization data and the policy model's distrib ution. Our first contribution is a systematical analysis of the diffusion trajec tories across different timesteps and identify that the instability primarily or iginates from early timesteps with low importance weights. To address these issu es, we propose SIPO, a Stabilized and Improved preference Optimization framework for aligning diffusion models with human preferences. Concretely, a key gradien t, \emph{i.e.,} DPO-C&M is introduced to facilitate stabilize training by clippi ng and masking uninformative timesteps. Followed by a timestep aware importance re-weighting paradigm to fully correct off-policy bias and emphasize informative updates throughout the alignment process. Extensive experiments on various base line models, including image generation models on SD1.5, SDXL, and video generat ion models CogVideoX-2B, CogVideoX-5B, and Wan2.1-1.3B, demonstrate that our SIP O consistently promotes stabilized training and outperforms existing alignment m ethods, with meticulous adjustments on parameters. Overall, these results highli ght the importance of timestep-aware alignment and and provide valuable guidelin es for improved preference optimization in diffusion models.

RLAnything: Forge Environment, Policy, and Reward Model in Completely Dynamic RL System
Yinjie Wang, Tianbao Xie, Ke Shen, Mengdi Wang, Ling Yang

The quality of both the environment and the reward model fundamentally governs t
he effectiveness of reinforcement learning. Accordingly, we propose RLAnything,
a reinforcement learning framework that dynamically optimizes each component thr
ough closed-loop optimization, amplifying learning signals and strengthening the
 overall system.
Specifically, the policy is trained with integrated feedback from step-wise and
outcome signals, while the reward model is jointly optimized via consistency fee
dback, which in turn further improves policy training. Moreover, our theory-moti
vated automatic environment adaptation improves training for both the reward and
 policy models by leveraging critic feedback from each, enabling learning from e
xperience.
Empirically, each added component consistently improves the overall system, and
RLAnything yields substantial gains in practical applications, boosting Qwen3-VL
-8B-Thinking by 8.5% on OSWorld and Qwen2.5-7B-Instruct by 21.2% and 12.1% on Al
fWorld and LiveBench, respectively.

Graph Rewiring based on Flow Alignment for Improving Fluid Simulation
Zenong Li, Wei Xian Lim, Wai Lee Chan, Adams Wai-Kin Kong
To overcome the computational burden of traditional computational fluid dynamics
 (CFD), graph neural network-based (GNN) learned simulators have attracted growi
ng interest because they naturally operate on CFD meshes. However, classical GNN
s only exchange information between neighbouring nodes, limiting flow prediction
 accuracy. While graph rewiring can improve information propagation, existing me
thods are mostly designed for generic graphs, and PIORF relies on long-range con
nections for fluid simulation. In this work, we show that simply connecting all
2-hop nodes can already achieve competitive performance with PIORF, raising ques
tions about the necessity of distant rewiring. Motivated by fluid transport prin
ciples, we propose Flow Alignment Rewiring (FLARE), a simple and efficient local
 rewiring method that connects 2-hop nodes only when their relative direction al
igns with the input flow direction. Hence, FLARE is a physics-informed local rew
iring method, different from PIORF and well-aligned with fluid physics. Extensiv
e numerical experiments on flows over a cylinder, single-, and tandem-airfoil un
der different flow conditions and deep network architectures demonstrate that FL
ARE outperforms PIORF and various 2-hop rewiring approaches by a significant mar
gin.

Translation Heads: Disentangling meaning from language in LLM-based machine tran
slation
Théo Lasnier, Armel Randy Zebaze, Djamé Seddah, Rachel Bawden, Benoît Sagot
Mechanistic Interpretability (MI) seeks to explain how neural networks implement
 their capabilities, but the scale of Large Language Models (LLMs) has limited p
rior MI work in Machine Translation (MT) to word-level analyses. We study senten
ce-level MT from a mechanistic perspective by analyzing attention heads to under
stand how LLMs internally encode and distribute translation functions. We decomp
ose MT into two subtasks: producing text in the target language (i.e. target lan
guage identification) and preserving the input sentence’s meaning (i.e. sentence
 equivalence). Across three families of open-source models and 20 translation di
rections, we find that distinct, sparse sets of attention heads specialize in ea
ch subtask. Based on this insight, we construct subtask-specific steering vector
s and show
that modifying just 1% of the relevant heads enables instruction-free MT perform
ance comparable to instruction-based prompting, while ablating these heads selec
tively disrupts their corresponding translation functions.

Adaptive Probe-based Steering for Robust LLM Jailbreaking
Junxi Chen, Junhao Dong, Xiaohua Xie
Recent work has demonstrated the potential of contrastive steering for jailbreak
ing Large Language Models (LLMs). However, existing methods rely on limited and
inherently biased contrastive prompts and require laborious manual tuning of ste
ering strength, limiting their robustness and effectiveness. In this paper, we l

everage the idea of model extraction to guide the learned steering vectors to ap
proximate the ideal one and propose tuning the steering strength adaptively base
d on contrastive activations' statistics. Experiments demonstrate that our metho
d notably improves the effectiveness and robustness of probe-based steering, wit
hout any extra contrastive prompts or laborious manual tuning. Being an attack p
aper, this paper focuses on revealing the breakdown of fortified LLMs, raising t
he average harmfulness score from 6\% to 70\%. Our code is available at \url{htt
ps://github.com/fhdnskfbeuv/adaptiveSteering}.

OneSearch: A Preliminary Exploration of the Unified End-to-End Generative Framew
ork for E-commerce Search
Ben Chen, Xian Guo, Siyuan Wang, Zihan Liang, Yufei Ma, Yue Lv, Chenyi Lei, Yuqi
ng DING, Wenwu Ou, Han Li, Kun Gai
Traditional e-commerce search systems employ multi-stage cascading architectures
 that suffer from fragmented computation and optimization objective collisions a
cross stages, ultimately limiting their performance ceiling.
We propose \textbf{OneSearch}, the first industrial-deployed end-to-end generati
ve framework for e-commerce search, featuring three key innovations: (1) Keyword
-enhanced Hierarchical Quantization Encoding to preserve hierarchical semantics
and distinctive item attributes while maintaining strong query-item relevance co
nstraints;
(2) multi-view user behavior sequence injection that constructs behavior-driven
user IDs and incorporates both explicit short-term and implicit long-term sequen
ces;
and (3) a Preference-Aware Reward System with multi-stage supervised fine-tuning
 and adaptive reward-weighted ranking to capture fine-grained user preferences.
Extensive offline evaluations demonstrate its superior performance, while online
 A/B tests achieve statistically significant improvements: +1.67\% item CTR, +2.
40\% buyer, and +3.22\% order volume. OneSearch reduces operational expenditure
by 75.40\%, improves Model FLOPs Utilization from 3.26\% to 27.32\%, and has bee
n successfully deployed across multiple search scenarios in Kuaishou, serving mi
llions of users daily.
Code is in https://github.com/benchen4395/onesearch-family.

Efficient Tail-Aware Generative Optimization via Flow Model Fine-Tuning
Zifan Wang, Riccardo De Santi, Xiaoyu Mo, Michael M. Zavlanos, Andreas Krause, K
arl Henrik Johansson
Fine-tuning pre-trained diffusion and flow models to optimize downstream utiliti
es is central to real-world deployment. Existing entropy-regularized methods pri
marily maximize expected reward, providing no mechanism to shape tail behavior.
However, tail control is often essential: the lower tail determines reliability
by limiting low-reward failures, while the upper tail enables discovery by prior
itizing rare, high-reward outcomes. In this work, we present Tail-aware Flow Fin
e-Tuning (TFFT), a principled and efficient distributional fine-tuning algorithm
 based on the Conditional Value-at-Risk (CVaR). We address two distinct tail-sha
ping goals: right-CVaR for seeking novel samples in the high-reward tail and lef
t-CVaR for controlling worst-case samples in the low-reward tail. Unlike prior
approaches that rely on non-linear optimization, we leverage the variational dua
l formulation of CVaR to decompose it into a decoupled two-stage procedure: a li
ghtweight one-dimensional threshold optimization step, and a single entropy-regu
larized fine-tuning process via a specific pseudo-reward. This decomposition ach
ieves CVaR fine-tuning efficiently with computational cost comparable to standar
d expected fine-tuning methods. We demonstrate the effectiveness of TFFT across
illustrative experiments, high-dimensional text-to-image generation, and molecul
ar design.

PULSE: Generative Phase Evolution for Non-Stationary Time Series Forecasting
Yangyou Liu, Zezhi Shao, Xinyu Chen, Hu Chen, Fei Wang, Yuankai Wu
Time series forecasting under non-stationarity faces a fundamental tension betwe
en capturing stable representations and adapting to distribution shifts. Existin

g methods implicitly rely on static historical assumptions, leading to a critica l failure mode we term *Phase Amnesia*, where models become blind to the evolvin g global context. To resolve this, we formalize non-stationary dynamics through three physical hypotheses: wold decomposition, dynamical phase evolution, and he teroscedastic manifold generation. These principles inspire **PULSE**, a physics -informed, plug-and-play framework adopting a *Disentangle--Evolve--Simulate* de sign philosophy. Specifically, PULSE utilizes phase-anchored disentanglement to resolve optimization interference caused by dominant trends, employs a Phase Rou ter to actively generate future trajectories, and introduces Statistic-Aware Mix up (SAM) to ensure robustness against out-of-distribution volatility. Empiricall y, PULSE enables a simple MLP backbone to achieve state-of-the-art or highly com petitive performance across 12 real-world benchmarks. This validates that a corr ect physics-informed inductive bias is far more critical than raw architectural complexity for non-stationary forecasting. The code is available at: https://git hub.com/Gemost/PULSE.

Teaching Molecular Dynamics to a Non-Autoregressive Ionic Transport Predictor

Jiyeon Kim, Byungju Lee, Won-Yong Shin

Unlike most static material properties widely studied in the machine learning li terature, ionic transport properties are inherently dynamic, making their fast a nd accurate prediction from static atomic structures challenging. The current st andard approach, molecular dynamics (MD) simulations, suffers from prohibitively high computational cost. Recent autoregressive learning-based MD acceleration m ethods requiring sequential inference remain slow and prone to error accumulatio n; in contrast, existing non-autoregressive material property prediction models are less accurate because they fail to exploit dynamics. Moreover, existing meth ods typically benefit from datasets either with or without atomic trajectories, but not both. To overcome these limitations, we propose a non-autoregressive lea rning framework based on auxiliary modality learning, which treats atomic trajec tories as an auxiliary modality during training but does not require them at inf erence. This enables the predictor to learn dynamics without sequential inferenc e while benefiting from both types of datasets. As a result, our framework achie ves over 200 times speedup compared to autoregressive models on the dataset with atomic trajectories while substantially reducing prediction error relative to n on-autoregressive benchmarks across both types of datasets. Our code is availabl e at https://github.com/jykim-git/MD.

Learning-Augmented Online Minimization with Dual Predictions

Christian Coester, Alexa Tudose, Alexander Turoczy

We present learning-augmented algorithms for two general classes of online minim ization problems: metrical task systems and laminar set cover. Both algorithms a chieve improved theoretical guarantees using machine-learned predictions of an o

ptimal solution to the dual linear program. Unlike optimal primal solutions, whi ch can change drastically under tiny instance perturbations, these dual solution s are much more stable, which ensures the existence of good (and learnable) pred ictions for families of similar instances. While previous work has used dual pre dictions in offline settings and for online maximization problems, our algorithm s are, to the best of our knowledge, the first demonstration that such dual pred ictions can be effective for online minimization. Our theoretical results are co mplemented by experiments on the k-server problem and the parking permit probl em.

Benchmarking Agent Memory in Interdependent Multi-Session Agentic Tasks

Zexue He, Yu Wang, Churan Zhi, Yuanzhe Hu, Tzu-Ping Chen, Lang Yin, Ze Chen, Ton g Arthur Wu, Siru Ouyang, Zihan Wang, Jiaxin Pei, Julian McAuley, Yejin Choi, Al ex Pentland

Existing evaluations of agents with memory typically assess **memorization** and **action** in isolation. One class of benchmarks evaluates memorization by test ing recall of past conversations or text but fails to capture how memory is used to guide future decisions. Another class focuses on agents acting in single-ses sion tasks without the need for long-term memory. However, in realistic settings , memorization and action are tightly coupled: agents acquire memory while inter acting with the environment, and subsequently rely on that memory to solve futur e tasks. To capture this setting, we introduce MemoryArena, a unified evaluation gym for benchmarking agent memory in multi-session Memory-Agent-Environment loo ps. The benchmark consists of human-crafted agentic tasks with explicitly interd ependent subtasks, where agents must learn from earlier actions and feedback by distilling experiences into memory, and subsequently use that memory to guide la ter actions to solve the overall task. MEMORYARENA supports evaluation across we b navigation, preference-constrained planning, progressive information search, a nd sequential formal reasoning, and reveals that agents with near-saturated perf ormance on existing long-context memory benchmarks like LoCoMo perform poorly in our agentic setting, exposing a gap in current evaluations for agents with memo ry.

****

Making Expert Reasoning Learnable with Self-Distillation

Ethan Mendes, Jungsoo Park, Alan Ritter

Improving the reasoning capabilities of large language models (LLMs) typically r elies either on the model's ability to sample a correct solution to be reinforce d or the existence of a stronger model able to solve the problem. However, many difficult problems remain intractable for even current frontier models, preventi ng the extraction of valid training signals. A promising alternative is to lever age high-quality expert human solutions, yet naive imitation of this data fails because it is fundamentally out-of-distribution: expert solutions are typically didactic, containing implicit reasoning gaps intended for human readers rather t han computational models. Furthermore, high-quality expert solutions are expensi ve, necessitating generalizable sample-efficient training methods. We propose Di stribution Aligned Imitation Learning (DAIL), a two-step self-distillation metho d that bridges the distributional gap by first transforming expert solutions int o detailed, in-distribution reasoning traces and then applying a contrastive obj ective to focus learning on expert insights and methodologies. We find that DAIL can leverage fewer than 1000 high-quality expert solutions to achieve up to 31% pass@128 gains on Qwen2.5-Instruct and Qwen3, double reasoning efficiency, and enable out-of-domain generalization.

****

Online Change Point Detection for Multivariate Inhomogeneous Poisson Processes T ime Series

Xiaokai Luo, Haotian Xu, Carlos Misael Madrid Padilla, OSCAR HERNAN MADRID PADIL LA

We study online change point detection for multivariate inhomogeneous Poisson po int process time series. This setting arises commonly in applications such as ea rthquake seismology, climate monitoring, and epidemic surveillance, yet remains

underexplored in the machine learning and statistics literature. We propose a method that uses low-rank matrices to represent the multivariate Poisson intensity functions, resulting in an adaptive nonparametric detection procedure. Our algorithm is single-pass and requires only constant computational cost per new observation, independent of the elapsed length of the time series. We provide theoretical guarantees to control the overall false alarm probability and characterize the detection delay under temporal dependence. We also develop a new Matrix Bernstein inequality for temporally dependent Poisson point process time series, which may be of independent interest.
Numerical experiments demonstrate that our method is both statistically robust and computationally efficient.

Out-of-Distribution Evaluation of Rule-Based and Strategic Reasoning in Chess Transformers
Anna Mészáros, Patrik Reizinger, Ferenc Huszár
Modern decision transformers, trained similarly to LLMs, can achieve strong in-distribution performance in complex sequential domains like chess, but it remains unclear to what extent they reason systematically about rules and strategy. We study the reasoning capabilities of a 270M-parameter chess transformer trained via behavior cloning on standard chess. To investigate its abilities, we construct out-of-distribution test sets ---including board states and variants never seen during training---designed to reveal failures of systematic generalization. Our analysis shows that the model exhibits robust rule-based reasoning, consistently generating legal moves in novel configurations, but its strategic reasoning is more limited. The model generates high-quality moves on curated OOD puzzles and shows basic strategy adaptation in full games. It underperforms symbolic AI algorithms that rely on explicit search, although the performance gap is smaller when playing against human users on Lichess. Moreover, the training dynamics reveals distinct phases in how the model learns to respect the fundamental constraints, suggesting an emergent compositional understanding of the game.

A robust PPG foundation model using multimodal physiological supervision
Eloy Geenjaar, Vince D. Calhoun, scott daly, Gouthaman KV, Lie Lu, Trisha Mittal, Daniel P. Darcy
Photoplethysmography (PPG), a non-invasive measure of changes in blood volume, is widely used in both wearable devices and clinical settings. Recent PPG foundation models either use open-source ICU datasets with pretraining paradigms that require curated data and thus complicate generalization to field-like data, or use closed-source field-like PPG data. In contrast, we propose a PPG foundation model that does not require high-quality or field-like pretraining data, and instead leverages accompanying electrocardiogram and respiratory signals in ICU datasets to select contrastive samples during pretraining. Our approach allows the model to retain and learn from noisy PPG segments, improving robustness at inference. Our model, pretrained on 3x fewer subjects than existing state-of-the-art approaches, achieves performance improvements on 14 out of 15 diverse downstream tasks, including field-like daily activity and heart rate prediction. Our results demonstrate that multimodal supervision can integrate complementary physiological information to improve the robustness of PPG foundation models and enhance their generalization to consumer-grade data.

TuneAhead: Predicting Fine-tuning Performance Before Training Begins
Yuxiang Luo, Haonan Long, Chen Wang, Qiqi Duan, Xiaotian Lin, Yanwei Xu, Yuyu Luo, Weikai Yang, Nan Tang
Fine-tuning large language models (LLMs) is compute-intensive and error-prone: model performance depends sensitively on data quality and hyperparameter choices, and naïve runs can even degrade model performance. This raises a practical question:can we predict fine-tuning performance before committing to a full training run? We present TUNEAHEAD, a lightweight framework for pre-hoc prediction of fine-tuning performance. TUNEAHEAD encodes each candidate run as a meta-feature vector that combines static dataset descriptors with dynamic probe features

from a short standardized probe. A predictor maps these features to performance estimates, while SHAP-based attributions provide interpretable diagnostics that reveal which specific features drive
the prediction. Across 1,300+ fine-tuning runs on
Qwen2.5-7B-Instruct, TUNEAHEAD consistently
outperforms strong baselines such as Early-Stop
Extrapolation and ProxyLM. On a held-out test
set of 370 runs, TUNEAHEAD achieves an RMSE
of 1.47 percentage points and places 95.1% of predictions within ±3 percentage p oints of the true
score. These accurate continuous predictions support practical go/no-go screenin g policies that can
reduce unnecessary full fine-tuning while retaining most promising runs.

ScalingAR: Scaling Confidence for Autoregressive Image Generation

Harold Haodong Chen, Xianfeng Wu, Wen-Jie Shu, Rongjin Guo, Disen Lan, Harry Yan g, Ying-Cong Chen

Test-time strategies have shown remarkable success in improving large language m odels, but their application to next-token prediction (NTP) autoregressive (AR) image generation remains largely underexplored. Existing test-time scaling (TTS) methods for visual autoregressive models (VAR) rely on frequent partial decodin g and external reward models, which are inefficient and often ineffective for NT P-based image generation due to the inherent instability of intermediate decodin g results. To address these limitations, we propose **ScalingAR**, a novel test- time scaling framework tailored for NTP-based AR image generation. ScalingAR int roduces *token entropy* as a confidence signal and operates at two complementary levels: (***i***) ***Profile Level***, integrates intrinsic uncertainty and con ditional utilization into a unified confidence state, and (***ii***) ***Policy L evel***, leverages this state for adaptive trajectory pruning and dynamic guidan ce scheduling. Without requiring early decoding or auxiliary rewards, ScalingAR achieves significant improvements across diverse benchmarks. Experiments show th at ScalingAR **(I)** improves base models by 12.5% on GenEval and 15.2% on TIIF- Bench, **(II)** reduces visual token consumption by 62.0% while outperforming ba selines, and **(III)** enhances robustness, mitigating performance degradation b y 26.0% in challenging scenarios. These results establish ScalingAR as a robust and efficient test-time scaling solution for autoregressive image generation.

Chamaileon: Cross-Context Binder Design with Contextualized Modeling and Mixed S ampling

Hengyuan Cao, Shizhuo Cheng, Mingxuan Liu, Weicheng Huang, Yunhong Lu, CAI CHENX I, Yan Zhang, Min Zhang

The rapid evolution of generative models has unlocked new potentials in protein binder design, a pivotal task in structural biology, by facilitating end-to-end generation via joint sequence-structure modeling or hallucination. However, exis ting approaches are predominantly implemented under a single-target, single-stat e assumption, limiting their ability to model multi-target or multi-state intera ctions required for advanced function-oriented protein design. Here, we introduc e Chamaileon, which unifies multi-target and multi-state binder design by formul ating the problem as cross-context binding landscape modeling. The framework is underpinned by a training paradigm termed \textit{In-Context Complex Co-Design (I3CD)} for context-aware sequence-structure co-modeling. During inference, we em ploy \textit{Mixture-of-Paths Sampling (MoPS)}, a scalable strategy that optimiz es a single sequence across contexts while alleviating the scarcity of high-qual ity multi-conformational paired data. Extensive evaluation on our newly construc ted benchmark, \textit{CROSS}, demonstrates that Chamaileon effectively generate s sequences adaptable to diverse conformational landscapes and multi-target requ irements.

Chain-of-Glimpse: Search-Guided Progressive Object-Grounded Reasoning for Video Understanding

Zhixuan Wu, Quanxing Zha, Teng Wang, Genbao Xu, Wenyuan Gu, Wei Rao, Nan Ma, Bo Cheng, Soujanya Poria

Video understanding requires identifying and reasoning over semantically discriminative visual objects across frames, yet existing object-agnostic solutions struggle to effectively handle substantial object variations over time. To address this, we introduce Chain-of-Glimpse, a search-guided progressive object-grounded reasoning framework that explicitly anchors each reasoning step to specific visual evidence regions, enabling compositional and multi-step decision-making. Formally, Chain-of-Glimpse formulates video reasoning as a step-by-step process that incrementally builds spatially grounded traces around task-relevant visual objects, thereby mitigating over-reliance on saliency-driven cues. Specifically, Chain-of-Glimpse features a search-guided controller, optimized via reinforcement learning with a format reward that significantly incentivizes grounding capability, to iteratively ground visual evidence regions and form reliable reasoning trajectories, yielding accurate and interpretable multi-step decisions. Extensive evaluations across two categories of video reasoning benchmarks, including general video reasoning benchmarks such as NExTQA, Video-Holmes, CG-Bench-Reasoning, and VRBench, and grounded video reasoning benchmarks such as NExT-GQA, demonstrate that Chain-of-Glimpse consistently improves performance while exhibiting strong robustness and generalization across diverse video reasoning tasks.

Parallel Stochastic Gradient-Based Planning for World Models

Michael Psenka, Michael Rabbat, Aditi S. Krishnapriyan, Yann LeCun, Amir Bar

World models simulate environment dynamics from raw sensory inputs like video. However, using them for planning can be challenging due to the vast and unstructured search space. We propose a robust and highly parallelizable planner that leverages the differentiability of the learned world model for efficient optimization, solving long-horizon control tasks from visual input. Our method treats states as optimization variables ("virtual states") with soft dynamics constraints, enabling parallel computation and easier optimization. To facilitate exploration and avoid local optima, we introduce stochasticity into the states. To mitigate sensitive gradients through high-dimensional vision-based world models, we modify the gradient structure to descend towards valid plans while only requiring action-input gradients. Our approach can be viewed as a stochastic version of a non-condensed or collocation-based optimal controller. We provide theoretical justification and experiments on video-based world models, where our resulting planner outperforms existing planning algorithms like the cross-entropy method (CEM) and vanilla gradient-based optimization (GD) on long-horizon experiments, both in success rate and time to convergence.

FoeGlass: Simple In-Context Learning Is Enough for Red Teaming Audio Deepfake Detectors

Sepehr Dehdashtian, Jacob H Seidman, Vishnu Boddeti, Gaurav Bharaj

Audio deepfake detection (ADD) models are critical for countering the malicious use of text-to-speech (TTS) models. Evaluating and strengthening ADD models requires developing datasets that span the space of generated audio and highlight high-error regions. Existing dataset development strategies face two challenges: (i) manual collection, and (ii) inefficient discovery of blind spots in the ADD models. To address these challenges, we propose FoeGlass, the first black-box automated red-teaming method for ADDs, which effectively discovers ADD failure modes in the space of generated audio underexplored by state-of-the-art deepfake benchmarks. FoeGlass uses the in-context learning capabilities of an LLM to explore the input space of a TTS model, generating audio samples that fool the target ADD using only black-box access to all components. By using a carefully designed context based on diversity measurements, FoeGlass mitigates the common problem of mode collapse in automated red-teaming systems. Empirical evaluations on several open-source ADD and TTS models demonstrate that data generated from FoeGlass substantially improves the false negative rates over unconditional sampling baselines and recent spoofing datasets by up to 94%, while requiring no manual supervision. Furthermore, we show that the attacks generated by FoeGlass are transfer

able across different target ADDs, demonstrating its broad applicability and eas
e of use for the automated red teaming of ADD systems. Finally, fine-tuning ADD
models on FoeGlass-generated samples notably enhances the robustness of the dete
ctors (up 41%).

Mind the Gap: Structure-Aware Consistency in Preference Learning
Mehryar Mohri, Yutao Zhong
Aligning Large Language Models (LLMs) with human intent, whether through explici
t reward modeling or direct methods such as DPO, fundamentally relies on minimiz
ing a surrogate loss as a proxy for the true pairwise ranking objective. We prov
e that this reliance is flawed for the standard surrogate losses used: for the e
quicontinuous hypothesis sets characteristic of neural networks, *no* standard s
urrogate provides a meaningful consistency guarantee. Minimizing the surrogate l
oss to zero can leave the true ranking error arbitrarily high. To resolve this,
we formulate LLM alignment within a margin-shifted ranking framework and derive
H-consistency bounds showing that enforcing a confidence margin γ is no
t merely beneficial but *necessary* for consistency. We further introduce Struct
ure-Aware H-consistency and a corresponding objective (SA-DPO) that adapts the
 margin to the semantic distance between responses, preventing instability on ne
ar-synonymous pairs. Finally, we analyze the trade-off between the margin requir
ed for consistency and the model's finite capacity to satisfy it, revealing a st
rict hierarchy of surrogate losses: heavy-tailed surrogates (e.g., the Polynomia
l Hinge family) offer strictly superior consistency guarantees for capacity-boun
ded models compared to the logistic loss used in DPO. Experiments on UltraFeedba
ck and Argilla DPO-Mix-7k confirm that SA-DPO consistently outperforms DPO and S
imPO, with a 58.5\% head-to-head win-rate in downstream generation quality.
****
The Crowded Embedding Space: A Mean-Field Mechanism for Emergent Marginalization
 in Retrieval-Augmented Agents
Shwan Ashrafi, Dan Roth
Retrieval-augmented generative agents rely on retrieval for grounding, yet are t
ypically evaluated on a query-by-query basis. This isolates interactions that ar
e geometrically coupled in a shared embedding space. For example, we show that t
he high document density required to serve majority interests (e.g., generic "Cr
ime" movies) can geometrically overcrowd the retrieval neighborhood of a semanti
cally similar minority (e.g., "Film Noir"), effectively expelling minority conte
nt from top-k results. We introduce a formal framework to analyze how such *go
al collisions* in dense retrieval induce fundamental performance limits and emer
gent fairness issues inherent to spatial crowding. In our static analysis, we de
monstrate that for a fixed embedding space, a phase transition occurs where mino
rity user goals suffer a catastrophic collapse in performance as the density of
majority goals increases. We then extend this to a dynamic model and derive a no
n-linear Fokker-Planck equation that governs the evolution of document embedding
s as the agent updates them to maximize retrieval accuracy. Our analysis reveals
 that this local relevance objective triggers an emergent global mechanism that
systematically marginalizes minority interests. We prove that such objectives dr
ive the system to self-organize into a state that exclusively serves majority in
terests. These results provide a theoretical foundation for understanding a crit
ical grounding failure mode in retrieval-augmented agents.

Entropy-Aware On-Policy Distillation of Language Models
Woogyeol Jin, Taywon Min, Yongjin Yang, Dennis Wei, Yi Zhou, Swanand Ravindra Ka
dhe, Nathalie Baracaldo, Kimin Lee
On-policy distillation is a promising approach for transferring knowledge betwee
n language models, where a student learns from dense token-level signals along i
ts own trajectories. This framework typically uses reverse KL divergence, encour
aging the student to match the teacher's high-confidence predictions. However, w
e show that the mode-seeking property of reverse KL reduces generation diversity
 and yields unstable learning signals when the teacher distribution has high ent
ropy. To address this, we introduce Entropy-Aware On-Policy Distillation. Our ke

y idea is augmenting the standard reverse KL objective with forward KL when teac
her entropy is high, capturing the full range of plausible outputs while retaini
ng precise imitation elsewhere. It balances mode-seeking precision with mode-cov
ering robustness without sacrificing on-policy training efficiency. Experiments
 show that our method maintains generation diversity (sustained token-level entro
py) and improves student–teacher alignment (lower forward KL on high-entropy tok
ens). Across six math reasoning benchmarks, this yields Pass@8 accuracy gains of
 $+1.37$ for Qwen3-0.6B-Base, $+2.39$ for Qwen3-1.7B-Base, and $+5.05$ for Qwen3
-4B-Base compared to baseline on-policy distillation methods. These results demo
nstrate that accounting for teacher uncertainty is essential for maintaining div
ersity and achieving effective knowledge transfer. Our code is publicly availabl
e at https://github.com/WLS04/EOPD.

AutoBaxBuilder: Bootstrapping Code Security Benchmarking
Tobias von Arx, Niels Mündler, Mark Vero, Maximilian Baader, Martin Vechev
As large language models (LLMs) see wide adoption in software engineering, the r
eliable assessment of the correctness and security of LLM-generated code is cruc
ial. Notably, prior work showed that LLMs are prone to generating code with secu
rity vulnerabilities, highlighting that security is often overlooked. These insi
ghts were enabled by specialized benchmarks crafted by security experts through
 significant manual effort. However, benchmarks (i) inevitably end up contaminati
ng training data, (ii) must extend to new tasks to provide a more complete pictu
re, and (iii) must increase in difficulty to challenge more capable LLMs. In thi
s work, we address these challenges and present AutoBaxBuilder, an automated pip
eline that generates code security benchmarking tasks from scratch. It leverages
 the code-understanding capabilities of LLMs combined with robust reliability ch
ecks to construct functional tests and end-to-end security-probing exploits. The
 quality of the pipeline is quantitatively confirmed by aligning its predictions
 with an expert-written baseline and qualitatively validated through manual soun
dness verification. We use AutoBaxBuilder to construct a new benchmark and relea
se it to the public as AutoBaxBench, together with a thorough evaluation on cont
emporary LLMs. AutoBaxBuilder generates new tasks in under 2 hours, for less tha
n USD 4. Including a manual verification, this reduces the required human effort
 for benchmark construction by a factor of 12.

Uncertainty-Guided Exploration and Stable Planning for Sparse-Reward Manipulatio
n from Limited Demonstrations
Haowen Sun, Liqi Huang, Mingyang Li, Sihua Ren, Xinzhe Chen, Chengzhong Ma, Zeya
ng Liu, Xingyu Chen, Xuguang Lan
Reinforcement learning from demonstrations (RLfD) offers a promising method for
 robotic manipulation with sparse rewards. However, limited demonstrations often
 cause agents to encounter out-of-distribution states where world models produce
 poor predictions. In multi-stage tasks, jointly optimizing a learned reward func
tion and policy introduces a moving target problem, and the resulting non-statio
narity intensifies the impact of uncertainty on policy learning. In this work, w
e propose QUEST, a model-based RL framework that adaptively switches between exp
loration and exploitation guided by uncertainty to achieve stable and efficient
 learning. Specifically, our approach employs intrinsic rewards to encourage expl
oration, leverages ensemble dynamics for uncertainty-guided planning, and introd
uces a hybrid sampling strategy to prioritize rare successful stage transitions.
 We evaluate QUEST on challenging sparse-reward manipulation tasks with limited
 expert demonstrations. Results show that QUEST outperforms state-of-the-art meth
ods by 17\% on average, with gains increasing to 60\% on difficult tasks. We fur
ther demonstrate successful zero-shot sim-to-real transfer on five real-world ta
sks. Project website: https://quest-official.github.io/QUEST/.

Hedging on the Frontier: Learning New Tasks with Few Samples
Tobias Wegel, Federico Di Gennaro, Geelon So, Fanny Yang
When a learner faces a new task with few samples, it must leverage any available
 side information. In practice, this often comes in the form of model evaluation

s on related tasks in public benchmarks. A key question then is how to model tas
k relatedness such that it is both realistic and the benchmark evaluations lead
to provable gains. Empirically, we observe that *weak monotonicity* is often app
roximately satisfied: if a model dominates another on many benchmarks, it also t
ends to outperform on the new task. We explore the statistical complexity of lea
rning under (approximate) weak monotonicity, leveraging it within two learning p
aradigms: transfer learning and model selection aggregation. We show that not on
ly can we prune the model class based on monotonicity, but we can also further a
dapt to the geometry of the available trade-offs by *hedging on the frontier*.

Revisiting Pre-Propagation GNNs: Robust Diffusion Operators and Hidden-State Re-Propagation
Zichao Yue, Zhiru Zhang
Pre-propagation graph neural networks (PP-GNNs) decouple node feature propagatio
n from transformation: graph diffusion is performed once as preprocessing, and t
raining reduces to dense per-node transformations. This design enables mini-batc
h training without inter-node dependencies, avoids repeated sparse matrix--matri
x multiplications, and better matches modern accelerators optimized for dense co
mpute. However, their expressivity remains unclear, and empirical results show a
 gap between PP-GNNs and their message-passing counterparts on commonly used gra
ph benchmarks, especially heterophilic ones. In this paper, we propose a suite o
f robust graph diffusion operators for preprocessing and a few-shot hidden-state
 re-propagation scheme during training. Our methods improve the validation and t
est accuracy of PP-GNNs, enabling them to match the accuracy of message-passing
GNNs while maintaining training efficiency.

Grounded in Reality: Learning and Deploying Proactive LLM from Offline Logs
Fei Wei, Daoyuan Chen, Ce Wang, Yilun Huang, Yushuo Chen, Xuchen Pan, Yaliang Li
, Bolin Ding
Large language models (LLMs) are strong passive responders, but learning to proa
ctively elicit information—asking the right questions and stopping at the right
time—remains difficult. Existing approaches, such as optimizing turn-level attri
butes or relying on user simulators to generate training trajectories, often str
uggle with a persistent reality gap.

We propose \texttt{Learn-to-Ask}, a simulator-free framework that learns proacti
ve questioning policies directly from offline expert conversations. Our key insi
ght is to leverage the \textbf{observed future} of each expert trajectory to der
ive dense, turn-level rewards that reflect expert long-horizon strategy, reducin
g policy learning to a sequence of supervised learning tasks that jointly enable
 LLMs to know \textbf{what to ask} and \textbf{when to stop}. To ensure the LLM-
generated contents, such as reward fidelity and sampling quality, align with exp
ectations, we further introduce an automated pipeline that calibrates the prompt
s with minimal human supervision.

Across multiple datasets and model scales, \texttt{Learn-to-Ask} consistently im
proves proactive information-seeking behavior. We also report a large-scale real
-world deployment where the trained agent surpasses an internal expert baseline
under professional audit, which demonstrates the effectiveness of our framework
and our rewards as a reality-validated proxy metric for LLM proactivity.
****

Amodal Instance Segmentation with IRAIS Dataset for Sim-to-Real Transfer
Bidong Chen, Lingui Li
Amodal instance segmentation is hindered by the scarcity of scalable and transfe
rable annotations. We introduce MaviGen, an automated 3D retail scene modeling a
nd rendering framework that generates photorealistic multi-view images with comp
lete amodal masks. Building on MaviGen, we present the IRAIS dataset, a sim-to-r
eal benchmark comprising a large-scale synthetic multi-view set (3D-IRAIS) and a
 human-annotated real image set (Real-IRAIS), both sharing unified label definit
ions and evaluation protocols to facilitate rigorous transfer studies. We propos

e EUREKA, an encoder-only, query-efficient network for amodal instance segmentat
ion that performs full-image multi-task inference via unified amodal/visible que
ries and dual mask heads. The dual heads enable mutual supervision between compl
ete and visible masks, while the conditional masked self-attention mechanism fur
ther strengthens occlusion reasoning. Experiments establish strong baselines on
IRAIS and achieve state-of-the-art performance on D2SA and COCOA-cls, demonstrat
ing substantial improvements in sim-to-real transfer.
****

Removing Sandbagging in LLMs by Training with Weak Supervision
Emil Ryd, Henning Bartsch, Julian Stastny, Joe Benton, Vivek Hebbar
As AI systems begin to automate complex tasks, supervision increasingly relies o
n weaker models or limited human oversight that cannot fully verify output quali
ty. A model more capable than its supervisors could exploit this gap through san
dbagging, producing work that appears acceptable but falls short of its true abi
lities. Can training elicit a model's best work even without reliable verificati
on? We study this using model organisms trained to sandbag, testing elicitation
techniques on problem-solving math, graduate-level science, and competitive codi
ng tasks. We find that training with weak supervision can reliably elicit sandba
gging models when supervised fine-tuning (SFT) and reinforcement learning (RL) a
re combined: SFT on weak demonstrations breaks the sandbagging behavior, enablin
g RL to then fully elicit performance. Neither method succeeds reliably alone—RL
 without SFT almost always leads to reward hacking rather than genuine improveme
nt, and SFT without RL fails to elicit full performance when the supervisor is m
uch weaker than the untrusted model. Critically, this relies on training being i
ndistinguishable from deployment; when models can distinguish between training a
nd deployment, they can perform well during training while continuing to sandbag
 afterward. Our results provide initial evidence that training is a viable mitig
ation against sandbagging, while highlighting the importance of making training
indistinguishable from deployment.

Beyond Heuristics: Learnable Density Control for 3D Gaussian Splatting
Zhenhua Ning, Xin Li, Jun Yu, Guangming Lu, Yaowei Wang, Wenjie Pei
While 3D Gaussian Splatting (3DGS) has demonstrated impressive real-time renderi
ng performance, its efficacy remains constrained by a reliance on heuristic dens
ity control. Despite numerous refinements to these handcrafted rules, such metho
ds inherently lack the flexibility to adapt to diverse scenes with complex geome
tries.

  In this paper, we propose a paradigm shift for density control from rigid heur
istics to fully learnable policies. Specifically, we introduce LeGS, a framework
 that reformulates density control as a parameterized policy network optimized v
ia Reinforcement Learning (RL). Central to our approach is the tailored effectiv
e reward function grounded in sensitivity analysis, which precisely quantifies t
he marginal contribution of individual Gaussians to reconstruction quality. To m
aintain computational tractability, we derive a closed-form solution that reduce
s the complexity of reward calculation from $O(N^2)$ to $O(N)$. Extensive experi
ments on the Mip-NeRF 360, Tanks \& Temples, and Deep Blending datasets demonstr
ate that LeGS significantly outperforms state-of-the-art methods, striking a sup
erior balance between reconstruction quality and efficiency.
****

ConEx: Human-Interpretable Saliency Maps via Concept-Aware Attribution
Yehonatan Elisha, Oren Barkan, Ziv Weiss Haddad, Noam Koenigstein
Many visual explanation methods in computer vision highlight pixel importance bu
t struggle to link these low-level cues to semantically meaningful concepts, lim
iting their interpretability and trustworthiness. We introduce Concept-based Exp
lanations (ConEx), a novel framework that bridges saliency visualization with co
ncept-based reasoning to provide both faithfulness and interpretability. ConEx a
utomatically discovers class-specific concepts and represents them through conce
pt activation vectors (CAVs), learned without manual supervision using an archit
ecture-specific masking mechanism that reduces noise introduced by the segmentat
ion masks to enhance concept purity. ConEx generates faithful saliency maps that

reveal where each concept appears in the image and how it contributes to the prediction. To evaluate the reliability of these learned concepts, we propose two complementary metrics, Vector-Concept Match (VCM) and Concept-Class Match (CCM), that quantify concept alignment and enable direct comparison with existing methods. Extensive experiments across diverse settings demonstrate that ConEx achieves state-of-the-art performance on faithfulness, segmentation, and concept-quality benchmarks. Overall, ConEx advances the field toward truly interpretable and concept-grounded explanations in vision models.
****
Beyond Point-wise Neural Collapse: A Topology-Aware Hierarchical Classifier for Class-Incremental Learning
HuiYu Yi, Xu Zhiming, Dunwei Tu, Zhicheng Wang, Baile Xu, Furao Shen
The Nearest Class Mean (NCM) classifier is widely favored in Class-Incremental Learning (CIL) for its superior resistance to catastrophic forgetting compared to Fully Connected layers. While Neural Collapse (NC) theory supports NCM's optimality by assuming features collapse into single points, non-linear feature drift and insufficient training in CIL often prevent this ideal state. Consequently, classes manifest as complex manifolds rather than collapsed points, rendering the single-point NCM suboptimal. To address this, we propose Hierarchical-Cluster SOINN (HC-SOINN), a novel classifier that captures the topological structure of these manifolds via a ``local-to-global'' representation. Furthermore, we introduce Structure-Topology Alignment via Residuals (STAR) method, which employs a fine-grained pointwise trajectory tracking mechanism to actively deform the learned topology, allowing it to adapt precisely to complex non-linear feature drift. Theoretical analysis and Procrustes distance experiments validate our framework's resilience to manifold deformations. We integrated HC-SOINN into seven state-of-the-art methods by replacing their original classifiers, achieving consistent improvements that highlight the effectiveness and robustness of our approach. Code is available at \url{https://github.com/yhyet/HC_SOINN}.
****
BOOSTAPR: Boosting Automated Program Repair via Execution-Grounded Reinforcement Learning with Dual Reward Models
Yuanhao Li, Hongbo Wang, Xiaotang Shang, Xunzhu Tang, Yiming Cao, Xuhong Chen
Reinforcement learning for program repair is hindered by sparse execution feedback and coarse sequence-level rewards that obscure which edits actually fix bugs. We present BoostAPR, a three-stage framework: (1) supervised fine-tuning on execution-verified demonstrations with reasoning traces, (2) training dual reward models—a sequence-level assessor and a line-level credit allocator—from execution outcomes, and (3) PPO optimization where the line-level model redistributes rewards to critical edit regions. This line-level credit assignment operates at an intermediate granularity naturally suited to code changes. Trained on SWE-Gym and evaluated on four benchmarks, BoostAPR achieves 40.7% on SWE-bench Verified (+22.9pp over the base model), 24.8% on Defects4J (Python→Java transfer), 84.5% on HumanEval-Java, and 95.0% on QuixBugs, showing competitive open-source performance with strong cross-language generalization.

Theoretical Investigation on Inductive Bias of Isolation Forest
Qin-Cheng Zheng, Shao-Qun Zhang, Shen-Huan Lyu, Yuan Jiang, Zhi-Hua Zhou
Isolation Forest (iForest) is one of the most widely used unsupervised anomaly detectors, owing to its efficiency and performance on large-scale tasks. Despite its broad applications, there is still a lack of theoretical understanding of iForest's empirical success. In this work, we study the inductive bias of iForest and examine when and to what extent it performs well. The main idea is to characterize the random growth process of iForest, in which both split dimensions and split values are selected randomly. We model the growth process of iForest as a random walk and derive the expected path length function, the outcome of iForest that determines the anomaly score, by analyzing the hitting time of the absorbing state. The infinite-sample size analysis reveals that, unlike k-Nearest Neighbor (k-NN), whose score reflects only the local density, the iForest path length combines the density and the centrality. Since central points naturally hav

e larger path lengths, iForest is therefore less sensitive to central anomalies. Analyses of fixed datasets corroborate this finding and further show that iForest is more parameter-adaptive than k-NN. Our study provides a theoretical understanding of the effectiveness of iForest and establishes a foundation for further exploration.
****
Byte Pair Encoding for Efficient Time Series Forecasting
Leon Götz, Marcel Kollovieh, Stephan Günnemann, Leo Schwinn
Existing time series tokenization methods predominantly encode a constant number of samples into individual tokens. This inflexible approach can generate excessive tokens for even simple patterns like extended constant values, resulting in substantial computational overhead. Inspired by the success of byte pair encoding, we propose the first pattern-centric tokenization scheme for time series analysis. Based on a discrete vocabulary of frequent motifs, our method merges samples with underlying patterns into tokens, compressing time series adaptively. Exploiting our finite set of motifs and the continuous properties of time series, we further introduce conditional decoding as a lightweight yet powerful post-hoc optimization method, which requires no gradient computation and adds no computational overhead. On recent time series foundation models, our motif-based tokenization improves forecasting performance by 40% and boosts efficiency by 2314% on average. Conditional decoding further reduces MSE by up to 48%. In an extensive analysis, we demonstrate the adaptiveness of our tokenization to diverse temporal patterns, its generalization to unseen data, and its meaningful token representations capturing distinct time series properties, including statistical moments and trends.
****
A_2DEPT: Large Language Model–Driven Automated Algorithm Design via Evolutionary Program Trees
Bin Chen, Shouliang Zhu, Beidan Liu, Yong Zhao, Tianle Pu, Huichun Li, Zhengqiu Zhu
Designing heuristics for combinatorial optimization problems (COPs) is a fundamental yet challenging task that traditionally requires extensive domain expertise. Recently, Large Language Model (LLM)-based Automated Heuristic Design (AHD) has shown promise in autonomously generating heuristic components with minimal human intervention. However, most existing LLM-based AHD methods enforce fixed algorithmic templates to ensure executability, which confines the search to component-level tuning and limits system-level algorithmic expressiveness. To enable open-ended solver synthesis beyond rigid templates, we propose Automated Algorithm Design via Evolutionary Program Trees (A$_2$DEPT), which treats LLMs as system-level algorithm architects.
A$_2$DEPT explores the vast program space via a tree-structured evolutionary search with hybrid selection and hierarchical operators, enabling iterative refinement of complete algorithms.
To make open-ended generation practical, we enforce executability with a lightweight program-maintenance loop that performs feedback-driven repair.
In experiments, A$_2$DEPT consistently outperforms state-of-the-art baselines across standard and highly constrained benchmarks, reducing the optimality gap by an average of 9.8\%. Our work implies that system-level algorithm synthesis is a viable and scalable paradigm for LLM-driven optimization.
****
TranX-Adapter: Bridging Artifacts and Semantics within MLLMs for Robust AI-generated Image Detection
Wenbin Wang, Yuge Huang, Jianqing Xu, Yue Yu, Jiangtao Yan, Shouhong Ding, Pan Zhou, Yong Luo
Rapid advances in AI-generated image (AIGI) technology enable highly realistic synthesis, threatening public information integrity and security. Recent studies have demonstrated that incorporating texture-level artifact features alongside semantic features into multimodal large language models (MLLMs) can enhance their AIGI detection capability. However, our preliminary analyses reveal that artifact features exhibit high intra-feature similarity, leading to an almost uniform

attention map after the softmax operation. This phenomenon causes attention dilu
tion, thereby hindering effective fusion between semantic and artifact features.
 To overcome this limitation, we propose a lightweight fusion adapter, TranX-Ada
pter, which integrates a Task-aware Optimal-Transport Fusion that leverages the
Jensen-Shannon divergence between artifact and semantic prediction probabilities
 as a cost matrix to transfer artifact information into semantic features, and a
n X-Fusion that employs cross-attention to transfer semantic information into ar
tifact features. Experiments on standard AIGI detection benchmarks upon several
advanced MLLMs, show that our TranX-Adapter brings consistent and significant im
provements (up to +6% accuracy). Code can be found in supplementary material.

Is One Layer Enough? Understanding Inference Dynamics in Tabular Foundation Mode
ls

Amir Rezaei Balef, Mykhailo Koshil, Katharina Eggensperger

Transformer-based tabular foundation models (TFMs) dominate small to medium tabu
lar predictive benchmark tasks, yet their inference mechanisms remain largely un
explored. We present the first large-scale mechanistic study of layerwise dynami
cs in 6 state-of-the-art tabular in-context learning models. We explore how pred
ictions emerge across depth, identify distinct stages of inference and reveal la
tent-space dynamics that differ from those of language models. Our findings indi
cate substantial depthwise redundancy across multiple models, suggesting iterati
ve refinement with overlapping computations during inference stages. Guided by t
hese insights, we design a proof-of-concept, looped single-layer model that uses
 only 20% of the original model’s parameters while achieving comparable performa
nce. The code is available at https://github.com/amirbalef/is_one_layer_enough.

Blending Neural Control Density Functions for Stabilization and Safety

Sahil Chaudhary, Chaitanya Murti, Chiranjib Bhattacharyya

Recent work on Neural Network-based methods for nonlinear control use Lyapunov F
unctions to obtain controllers with guarantees of stability. However, Lyapunov-b
ased methods are fundamentally limited: they cannot be used for smooth blending
with formal Region of Attraction (RoA) expansion guarantees, and also fail to ce
rtify stability when unstable equilibria or saddle points are present. Density f
unctions provide an alternate stability certificate, and address these limitatio
ns by certifying almost everywhere stability, and enable smooth blending of cont
rollers. Learning valid density certificates is challenging due to integrability
 constraints, and the effect of density-based blending controllers on RoAs is no
t well understood. In this work, we provide the first guarantee that controllers
 blended with density functions yield RoAs containing the union of the RoAs achi
eved by the constituent controllers. Then, we propose a novel exponential charac
terization of density functions that provably satisfies the integrability condit
ion, and introduce Neural Control Density Functions (NCDFs), that leverage this
new parameterization. We also extend NCDFs for synthesizing safe-stable controll
ers by combining NCDFs with control barrier functions (NCDF-CBFs). Our experimen
ts show that blended controllers obtain superior RoAs to state-of-the-art method
s like Neural Lyapunov Control and Sum-of-Squares based techniques.

Convergence of Two-Timescale Markovian Stochastic Approximations with Applicatio
ns in Reinforcement Learning

Vagul Mahadevan, Claire Chen, Shuze Daniel Liu, Shangtong Zhang

This work studies the convergence of two-timescale stochastic approximations (SA
),
a class of iterative algorithms that update two sets of parameters in fast and s
low timescales respectively. Notable examples of two-timescale SA in reinforceme
nt learning (RL) include temporal difference learning with gradient correction (
TDC) and actor-critic methods. Previously, the stability (i.e., boundedness) and
 convergence of two-timescale SA were only established under i.i.d. noise. This
work instead establishes the stability and convergence of two-timescale SA under
 Markovian noise, a setup that is more realistic in RL. Notably, we do not need
to use any projection operator and the noise does not need to live in a compact

space. Our key technical novelty is to control the fast timescale parameter with the running max of the slow timescale parameter, instead of with the current slow timescale parameter, as most prior works do. As a key application, we establish the first almost sure convergence of TDC with eligibility traces under off-policy learning with linear function approximation.
****

Near-Optimal Private Linear Regression via Iterative Hessian Mixing
Omri Lev, Moshe Shenfeld, Vishwak Srinivasan, Katrina Ligett, Ashia C. Wilson
We study differentially private ordinary least squares (DP-OLS) with bounded data (X,Y) via sketching-based mechanisms. While Gaussian sketching approaches have been explored for DP-OLS (Sheffet, 2017), they are typically viewed as less competitive than the Adaptive Sufficient Statistics Perturbation (AdaSSP) method (Wang, 2018), which directly perturbs the sufficient statistics $(X^{\top}X, X^{\top}Y)$. This method was shown to be close to information-theoretically optimal, while also exhibiting strong empirical performance. In this work, we propose \emph{Iterative Hessian Mixing} (IHM), an algorithm that builds on Gaussian-sketching approaches to DP-OLS and is inspired by the Iterative Hessian Sketch (Pilanci & Wainwright, 2016). We prove that IHM is differentially private and provide utility guarantees in the form of excess empirical risk bounds. These bounds improve upon those of AdaSSP by removing a multiplicative factor that can be as large as the square root of the data dimension. The design of the IHM is based on new accuracy guarantees that we present for prior Gaussian sketching approaches for DP-OLS, which clarify when these methods are expected to perform well and how IHM circumvents their inherent limitations.
We also conduct a rigorous empirical evaluation on a large suite of datasets, demonstrating that IHM consistently outperforms prior baselines, including AdaSSP.
****

Reasoning Models Are Test Exploiters: Rethinking Multiple Choice
Narun Krishnamurthi Raman, Taylor Lundy, Kevin Leyton-Brown
When evaluating Large Language Models (LLMs) in question-answering domains, multiple-choice question answering (MCQA) is widely used because it enables automatic grading. However, MCQA also exposes models to answer options that can be exploited in ways that inflate reasoning ability. We study this phenomenon across 15 question-answering benchmarks and 27 LLMs by systematically varying how and when models are exposed to answer options. For non-reasoning LLMs, MCQA can remain a good proxy for free-text performance when any chain-of-thought is produced only before the options are revealed. However, this "decoupled" format is not realizable for most reasoning models: they are designed to emit reasoning tokens whenever they are prompted, so if options are present they inevitably "reason over" the options. In practice, this makes reasoning models particularly effective at extracting signal from options, and can create large, misleading gains over free-text baselines. To characterize how models exploit MCQA, we introduce diagnostic probes that isolate option-only and question-plus-option exploitation pathways, and we quantify how design choices such as distractor strength and "none-of-the-above" answers effect exploitability. Finally, we examined the practice of multiple choice as an error diagnostic: inferring a model's mistake from the wrong option it picks. On benchmarks where reasoning can be expressed as code, we ask models to output code, we then executed it varying the inputs, and compared the resulting input–output behavior, revealing failure modes that MCQA diagnostics obscure. Lastly, we offer practical guidelines when analyzing results from MCQA that better reflect LLMs' genuine reasoning capabilities.

Hamiltonian Asymmetric Fusion: One-Way Safe Directed Refinement under Modality Imbalance
Bingbing Chen, Congcong Liu, Dong Liang, Zhuo-Xu Cui
In RGB--D salient object detection, multimodal fusion is commonly implemented via symmetric token interaction, implicitly allowing information to flow in both directions. Under *modality imbalance*---when an auxiliary stream is substantially noisier than a designated primary stream---such symmetry creates a *backflow channel* that injects auxiliary noise into the primary representation and amplifi

es errors across iterative refinement stages. We formulate fusion in this regime as *directed refinement with one-way safety*: the primary modality defines a guidance field, while only auxiliary representations are iteratively purified, and primary perturbations induced by the auxiliary stream are explicitly bounded.
We propose *Hamiltonian Asymmetric Fusion* (HAF), a lightweight unrolled refinement block that updates auxiliary tokens with momentum regularization and gated driving. The refinement force is instantiated by FFT-based spectral global correlation and modulated by a shared learnable spectral response to emphasize reliable frequency components with minimal parameters; a leaky momentum gate and a stable integrator improve multi-step refinement stability. We provide guarantees of auxiliary error contraction and bounded primary perturbation, which symmetric fusion operators do not satisfy under imbalance. Experiments on six RGB--D SOD benchmarks show consistent gains and substantially more graceful degradation under controlled auxiliary corruption.

Infinite-Dimensional Generative Diffusions via Doob’s h-Transform
Thorben Pieper-Sethmacher, Daniel Paulin
This paper introduces a rigorous framework for defining generative diffusion models in infinite dimensions via Doob's h-transform. Rather than relying on time reversal of a noising process, a reference diffusion is forced towards the target distribution by an exponential change of measure.
Compared to existing methodology, this approach readily generalises to the infinite-dimensional setting, hence offering greater flexibility in the diffusion model.
The construction is derived rigorously under verifiable conditions, and bounds with respect to the target measure are established.
We show that the forced process under the changed measure can be approximated by minimising a score-matching objective and validate our method on both synthetic and real data.
****

Deterministic Component Mining for Multi-Framework UI2Code Generation
Zixiong Yang, Linxiao Li, Jiaye Lin, Binrui Wu, Xiaoyu Kang, Jiechao Gao
Automating User Interface (UI) generation substantially improves productivity and accelerates development by reducing engineering time and manual effort. Despite recent progress of Multimodal Large Language Models (MLLMs) in UI2Code, most existing approaches focus on a single HTML/CSS form and fail to systematically incorporate front-end frameworks such as React, Vue, and Angular.
Moreover, their outputs are often verbose and hard to reuse at the component level. To address those issues, we propose Deterministic Component Mining (DCM), a multi-stage pipeline that couples MLLMs with a compact intermediate representation to enable multi-framework and component-oriented code generation.
Firstly, a lightweight structure model predicts the representation of the DOM tree in JSON format, capturing the coarse layout from a webpage screenshot. Subsequently, we formulate deterministic rules to normalize the predicted DOM tree and mine reusable components with repetitive patterns via structural hashing and clustering, thereby yielding a portable intermediate representation.
Finally, we employ a framework-conditioned prompting strategy governed by a binding specification and a file-block protocol to emit HTML/React/Vue/Angular code with explicit component props and repeat constructs. Extensive experiments demonstrate that DCM significantly outperforms baselines on automatic evaluation metrics and component-level reuse, while delivering consistent gains in multi-framework portability and overall code structural quality.

IDRBench: Understanding the Capability of Large Language Models on Interdisciplinary Research
Yuanhao Shen, Daniel Xavier de Sousa, Ricardo Marçal de Andrade Nascimento, Hongyu Guo, Xiaodan Zhu
Innovation is a key driving force of human civilization. As the body of knowledge has grown considerably, bridging knowledge across different disciplines, where significant innovation often emerges, has become increasingly challenging. The

recent advancements in machine learning models, particularly Large Language Models (LLMs), have provided effective access to extensive knowledge sources and shown impressive abilities in reasoning, rendering significant opportunities for interdisciplinary discovery. Our research aims to understand the capabilities of state-of-the-art LLMs in integrating knowledge from different fields for interdisciplinary research (IDR). To address this fundamental problem, we introduce IDRBench, a pioneering framework that includes both datasets and evaluation tasks: (1) IDR Paper Identification, (2) IDR Idea Integration, and (3) IDR Idea Recommendation. Our study on ten mainstream LLMs provides a comprehensive analysis of their behavior and establishes benchmarks and baselines for future research. To the best of our knowledge, IDRBench is the first to provide a comprehensive investigation of LLMs' IDR capability.

****

Adaptive Testing for LLM Evaluation: A Psychometric Alternative to Static Benchmarks

Peiyu Li, Xiuxiu Tang, Si Chen, Ying Cheng, Ronald Metoyer, Ting Hua, Nitesh V Chawla

Evaluating large language models (LLMs) typically requires thousands of benchmark items, making the process expensive, slow, and increasingly impractical at scale. Existing evaluation protocols rely on average accuracy over fixed item sets, treating all items as equally informative despite substantial variation in difficulty and discrimination. We introduce ATLAS, an adaptive testing framework based on Item Response Theory (IRT) that estimates model ability using Fisher information–guided item selection. ATLAS reduces the number of required items by up to 90% while maintaining measurement precision. For instance, it matches whole-bank ability estimates using only 41 items (0.157 MAE) on HellaSwag (5,600 items). We further reconstruct accuracy from ATLAS's ability estimates and find that reconstructed accuracies closely match raw accuracies across all five benchmarks, indicating that ability preserves the global performance structure. At the same time, provides finer discrimination within accuracy-equivalent models: among more than 3,000 evaluated models, 23--31% shift by more than 10 rank positions, and models with identical accuracies receive meaningfully different ability estimates. Code and calibrated item banks available at https://github.com/Peiyu-Georgia-Li/ATLAS.

SCOPE and SCION: A Benchmark and an Auditable Reference Pipeline for Schema Induction and Fusion from Text

Miaobo Hu, Xiaobo Guo, Shuhao Hu, BoKun Wang, Rui Chen, Xin Wang, Jun Xiao, Daren Zha

Schema graphs are an upstream bottleneck of schema-grounded information extraction and knowledge graph construction, yet most extraction systems assume the schema is already available.

We introduce SCOPE (Schema Construction and Ontology-induction Pipeline Evaluation), a train-text-only benchmark for corpus-to-schema induction and optional schema fusion from raw text, built from 24 public information extraction sources (15 RE and 9 EE) normalized into evaluation-only gold schema graphs; its core event-extraction target covers event types and within-event argument roles, with inter-event links reported separately.

We present SCION (Schema Construction and Induction with Ontology Normalization), an auditable reference pipeline rather than a new extraction architecture; it constructs candidate spaces from train text and restricts naming, merging, filtering, validation, and conservative fusion to candidate-linked evidence under strict JSON contracts.

On the SCOPE core suite, SCION-lite attains the highest F1 among released source-schema references, Text2Onto-style, LLM-only, and matched extract-then-aggregate baselines under Literal, Fuzzy, Continuous, and Graph schema-graph metrics, while the compact open-model SCION-RL variant reduces reliance on proprietary LLM schema engineers.

These results are reported against normalized typed-edge targets rather than as claims that induced schemas surpass human ontology design; the release includes

evidence-linked outputs, parse/fallback logs, candidate retention/merging logs, run manifests, code, and benchmark packages at https://github.com/wandugu/paper_scion.

DMCO: Budget-Aware Co-Optimization of Data Cleaning and AutoML
Xiaoou Ding, Zekai Qian, Siying Chen, Hongbin Hu, Chen Wang, Hongzhi Wang, Jianmin Wang
Data cleaning and automated machine learning (AutoML) are both crucial for reliable learning systems, yet are commonly treated as independent or sequential stages. This separation ignores their strong interaction and leads to inefficient use of limited computational budgets.We propose DMCO, a unified framework that jointly optimizes data cleaning and model construction under a fixed resource budget. DMCO reformulates the traditional two-stage pipeline into a time-sliced process, where data cleaning and AutoML are interleaved and adaptively scheduled. We introduce a gradient-based data cleaning sampling strategy with theoretical guarantees for minimizing gradient estimation variance, and integrates it with loss-driven sampling and progressive AutoML fitting to continuously leverage intermediate data quality improvements.Experiments on six real-world datasets show that DMCO consistently outperforms standalone data cleaning and AutoML baselines on both classification and regression tasks, as measured by F1 score and MSE. Under limited budgets, DMCO achieves up to 82.19% of the performance of full data cleaning with exhaustive AutoML, while remaining robust across different AutoML frameworks.

PretrainZero: Reinforcement Active Learning on Pretraining Data
Xingrun Xing, Zhiyuan Fan, Jie Lou, Guoqi Li, Jiajun Zhang, Debing Zhang
Recent reinforcement learning (RL) based large-thinking models demonstrate impressive expert-level abilities, i.e., software and math, but still rely heavily on verifiable rewards in specific domains, which places a significant bottleneck to extend the performance boundary of general reasoning capabilities. In this work, we propose PretrainZero, a reinforcement active learning framework built on the pretraining corpus to extend RL from domain-specific post-training to general pretraining. PretrainZero features the following characteristics: 1) Active pretraining objectives: inspired by the active learning ability of humans, PretrainZero learns a unified reasoning policy to actively identify reasonable and informative contents from pretraining corpus, and reason to predict these contents by RL. 2) Self-supervised learning: without any verifiable labels, pretrained reward models, or supervised fine-tuning, we directly pretrain reasoners from $3\sim30$B base models on the general Wikipedia corpus using RL, significantly breaking the verification data-wall for general reasoning. 3) Verification scaling: by tackling increasingly challenging masked spans, PretrainZero substantially enhances the general reasoning abilities of pretrained base models. With reinforcement learning on pretraining data, PretrainZero improves Qwen3-4B-Base for 8.43, 5.96 and 10.60 on MMLU-Pro, SuperGPQA and math average benchmarks. In post-training, the pretrained models can also serve as reasoning foundation models for downstream RLVR tasks.

Causal Matrix Completion under Multiple Treatments via Mixed Synthetic Nearest Neighbors
Minrui Luo, Zhiheng Zhang
Synthetic Nearest Neighbors (SNN) provides a principled solution to causal matrix completion under missing-not-at-random (MNAR) by exploiting local low-rank structure through fully observed anchor submatrices. However, its effectiveness critically relies on sufficient data availability within each treatment level, a condition that often fails in settings with multiple or complex treatments.
In this work, we propose Mixed Synthetic Nearest Neighbors (MSNN), a new entry-wise causal identification estimator that integrates information across treatment levels. We show that MSNN retains the finite-sample error bounds and asymptotic normality guarantees of SNN, while enlarging the effective sample size available for estimation. Empirical results on synthetic and real-world datasets illustr

ate the efficacy of the proposed approach, especially under data-scarce treatmen
t levels.
****
Biased Generalization in Diffusion Models
Jerome Garnier-Brun, Luca Biggio, Davide Beltrame, Marc Mezard, Luca Saglietti
Generalization in generative modeling is defined as the ability to learn an unde
rlying distribution from a finite dataset and produce novel samples, with evalua
tion largely driven by held-out performance and perceived sample quality. In pra
ctice, training is often stopped at the minimum of the test loss, taken as an op
erational indicator of generalization. We challenge this viewpoint by identifyin
g a phase of *biased generalization* during training, in which the model continu
es to decrease the test loss while favoring samples with anomalously high proxim
ity to training data. By training the same network on two disjoint datasets and
comparing the mutual distances of generated samples and their similarity to trai
ning data, we introduce a quantitative measure of bias and demonstrate its prese
nce on real images. We then study the mechanism of bias, using a controlled hier
archical data model where access to exact scores and ground-truth statistics all
ows us to precisely characterize its onset. We attribute this phenomenon to the
sequential nature of feature learning in deep networks, where coarse structure i
s learned early in a data-independent manner, while finer features are resolved
later in a way that increasingly depends on individual training samples. Our res
ults show that early stopping at the test loss minimum, while optimal under stan
dard generalization criteria, may be insufficient for privacy-critical applicati
ons.

Beyond Model Ranking: Predictability-Aligned Evaluation for Time Series Forecast
ing
Wanjin Feng, Yuan Yuan, Jingtao Ding, Yong Li
In the era of increasingly complex AI models for time series forecasting, progre
ss is often measured by marginal improvements on benchmark leaderboards. However
, standard evaluations rely on aggregate metrics (e.g., MSE) that conflate model
 capability with the intrinsic difficulty of the evaluated instances. To address
 this, we propose a diagnostic framework anchored in **Spectral Coherence Predic
tability (SCP)**, which provides an efficient $\mathcal{O}(N\log N)$ per-instanc
e difficulty reference and yields a corresponding linear MSE lower bound.
Complementing this, we introduce the **Linear Utilization Ratio (LUR)** to quant
ify how effectively models exploit linearly predictable structures across freque
ncies.
Experiments on synthetic and real-world benchmarks show that SCP aligns strongly
 with realized forecasting errors across diverse state-of-the-art forecasters.
Using this lens, we uncover ``predictability drift,'' revealing that task diffic
ulty is not static but fluctuates significantly over time and variables.
Furthermore, stratified evaluation exposes complementary architectural strengths
 across distinct frequency bands and difficulty regimes.
Overall, we advocate moving beyond leaderboard-style ranking toward a more insig
htful, predictability-aware evaluation that fosters fairer model comparisons and
 a deeper understanding of model behavior.
Code and data are available at https://github.com/WanjinVon/TS_Predictability.
****
Reasoning Cache: Continual Improvement Over Long Horizons via Short-Horizon RL
Ian Wu, Yuxiao Qu, Amrith Setlur, Aviral Kumar
Large Language Models (LLMs) that continue improving at test-time budgets far be
yond their training budgets can solve harder problems by leveraging additional i
nference compute: we refer to this property as extrapolation. Standard on-policy
 RL operates on fixed problem distributions and training budgets, giving rise to
 a distribution shift between train and test that limits the resulting model's e
xtrapolation capabilities. To address this, we introduce RC, an iterative decodi
ng algorithm replacing standard autoregressive decoding that enables models to e
xtrapolate to lengths an order of magnitude longer than those seen during traini
ng. RC exploits the asymmetry between summarization and generation capabilities

present in LLMs to construct a decoding process that improves consistently over iterations. Its effectiveness can be further increased through training, which amplifies the model’s ability to perform summary-conditioned reasoning while avoiding the challenges of long-horizon RL. Empirically, training a 4B instruction-following model with RC using a 16k-token training budget improves performance on HMMT 2025 from 40% to 70% when evaluated with a 512k-token test budget, substantially surpassing comparably sized LLMs.

Target-Oriented Pretraining Data Selection via Neuron-Activated Graph
Zijun Wang, Haoqin Tu, Weidong Zhou, Yiyang Zhou, Xiaohuan Zhou, Bingni Zhang, Weiguo Feng, Taifeng Wang, Cihang Xie, Fengze Liu
Everyday tasks come with a target, and pretraining models around this target is what turns them into experts. In this paper, we study target-oriented language model (LM) pretraining by introducing ***N**euron-**A**ctivated **G**raph Ranking* (NAG-based Ranking), a training-free and interpretable framework for target pretraining data selection.
Rather than using black-box representations, our approach directly characterizes each target input by a sparse set of high-impact neurons in any off-the-shelf LLMs.
Concretely, we quantify neuron impact and select the most influential neurons across layers into a compact ***N**euron-**A**ctivated **G**raph* (NAG), and rank candidate data by NAG similarity to target examples.
We conduct experiments across six benchmarks, where our NAG-based Ranking improves target-oriented pretraining by 4.9\% on average over random sampling, and also outperforms state-of-the-art baselines by 5.3\% accuracy on HellaSwag.
It also remains effective under a more applicable multi-target setting, where our best setup surpasses two baselines by 1.1\% and 4.1\%, respectively.
Furthermore, we provide a comprehensive analysis on *why* and *how* our NAG works, e.g., deactivating NAG-selected neurons (only 0.12\% of all) causes a 23.5\% performance collapse, and restricting NAG to the final
layer incurs a 4.1\% average drop, indicating that NAG captures a sparse ``functional backbone'' for learning target features.
We release the code at https://github.com/asillycat/NAG.
****
TextMesh4D: Zero-shot Text-to-4D Mesh Generation
Sisi Dai, Xinxin Su, Kai Xu
Large-scale, high-quality dynamic 3D (4D) assets are essential for learning physically grounded representations, but remain costly to capture and annotate at scale. This limits the viability of supervised 4D learning and motivates zero-shot text-to-4D generation leveraging pretrained diffusion priors. To model complex dynamics, prior methods typically adopt implicit 3D representations (e.g., NeRFs or 3DGS) for their deformation capacity. However, their implicit nature provides limited control over surface topology, which hinders high-fidelity geometry and makes temporally coherent surface reconstruction challenging. To address these limitations, we explore zero-shot text-to-4D mesh generation. However, a structural mismatch arises when combining diffusion-based guidance with topology-constrained meshes: the guidance is noisy and spatially inconsistent, while meshes impose severe topological constraints, making direct vertex-level deformation unstable. In this paper, we introduce TextMesh4D, the first zero-shot framework for text-to-4D that directly generates dynamic meshes by addressing the above challenge at two complementary levels. Geometrically, we shift deformation modeling from vertices to faces via a Jacobian Deformation Field (JDF), enabling topology-aware surface reconstruction through an integrability-enforcing integration formulation. Semantically, we propose a Local-Global Semantic Regularizer (LGSR) that preserves identity over time by jointly constraining local deformation plausibility and global shape consistency. Extensive experiments demonstrate state-of-the-art temporal consistency, structural fidelity, and visual quality, while remaining efficient on a single 24GB GPU.
****
MemCast: Memory-Driven Time Series Forecasting with Experience-Conditioned Reaso

ning
Xiaoyu Tao, Mingyue Cheng, Ze Guo, Shuo Yu, Yaguo Liu, Qi Liu, Shijin Wang
Time series forecasting (TSF) plays a critical role in decision-making for many real-world applications. Recently, large language model (LLM)- based forecasters have made promising advancements.
Despite their effectiveness, existing methods often lack explicit experience accumulation and continual evolution.
In this work, we propose MemCast, a learning-to-memory framework that reformulates TSF as an experience-conditioned reasoning task.
Specifically, we learn experience from the training set and organize it into a hierarchical memory. This is achieved by summarizing prediction results into historical patterns, distilling inference trajectories into reasoning wisdom, and inducing extracted temporal features into general laws.
Furthermore, during inference, we leverage historical patterns to guide the reasoning process and utilize reasoning wisdom to select better trajectories, while general laws serve as criteria for reflective iteration. Additionally, to enable continual evolution, we design a dynamic confidence adaptation strategy that updates the confidence of individual entries without leaking the test set distribution.
Extensive experiments on multiple datasets demonstrate that MemCast consistently outperforms previous methods, validating the effectiveness of our approach.
Our code is available at https://github.com/Xiaoyu-Tao/MemCast-TS.
****
Geometric Convergence of Gauss–Newton for Neural Networks: Riemannian Geometry and Adaptive Damping
Semih Cayci
Ill-conditioned kernel matrices can make first-order methods for training neural networks converge slowly. We establish non-asymptotic convergence bounds for the Gauss–Newton method in both under- and overparameterized regimes, showing it avoids these conditioning bottlenecks. In the underparameterized setting, Gauss–Newton gradient flow in parameter space induces a Riemannian gradient flow on a low-dimensional submanifold of function space. Using tools from Riemannian optimization, we show that, under an appropriate output scaling, the loss satisfies geodesic Polyak–Lojasiewicz and Lipschitz-smoothness conditions, implying geometric convergence to the optimal in-class predictor at an explicit rate independent of Gram-matrix conditioning. In the overparameterized setting, we identify adaptive, curvature-aware regularization schedules and prove fast geometric convergence to a global optimum for both Gauss–Newton gradient flow and discrete-time Gauss–Newton iterates, with rates independent of the minimum eigenvalue of the neural tangent kernel. Overall, Gauss–Newton can be provably faster in ill-conditioned regimes where first-order methods slow down.
****
KODA: Contrastive Representation Comparison and Alignment for Vision-Language Foundation Models
Youqi WU, Mohammad Jalali, Farzan Farnia
Vision-language foundation models such as CLIP and SigLIP provide widely used representations for multimodal learning systems. While these models are typically compared through downstream performance, such evaluations often do not explain how their representations differ structurally. In this work, we study this problem through the task of *Contrastive Embedding Clustering*: identifying sample subsets that are weakly clustered under one representation but strongly clustered under another. We propose *Kernel Optimization for Discrepancy Analysis (KODA)*, a kernel-based framework for contrastive representation comparison and alignment. KODA constructs unified multimodal kernels through modality-wise kernel composition and formulates discrepancy discovery as a constrained optimization problem that searches for coherent structures in one representation while suppressing coherence in a reference representation. This yields interpretable discrepancy directions associated with specific sample subsets and modality interactions. To scale KODA to large vision-language datasets, we develop randomized low-dimensional approximations of joint kernels using random projections, including Random Fo

urier Features for shift-invariant kernels. Empirically, KODA identifies consistent and interpretable discrepancy structures across vision-language representations and provides sample subsets for representation alignment. The code is available at https://github.com/yokiwuuu/KODA.

Optimal Transport for LLM Reward Modeling from Noisy Feedback

Licheng Pan, Haocheng Yang, Haoxuan Li, Yunsheng Lu, Yongqi Tong, Yinuo Wang, Shijian Wang, Zhixuan Chu, Lei Shen, Yuan Lu, Hao Wang

Reward models are fundamental to Reinforcement Learning from Human Feedback (RLHF), yet real-world datasets are inevitably corrupted by noisy preference. Conventional training objectives tend to overfit these errors, while existing denoising approaches often rely on homogeneous noise assumptions that fail to capture the complexity of linguistic preferences. To handle these challenges, we propose SelectiveRM, a framework grounded in optimal transport. We first devise a Joint Consistency Discrepancy to align the distribution of model predictions with preference data. Furthermore, to address the limitation of strict mass conservation which compels the model to fit outliers, we incorporate a Mass Relaxation mechanism via partial transport. This enables the autonomous exclusion of samples with noisy preference that contradict semantic consistency. Theoretically, we demonstrate that SelectiveRM optimizes a tighter upper bound on the unobserved clean risk. Extensive experiments validate that our approach significantly outperforms state-of-the-art baselines across diverse benchmarks.

Exploring Data-Free LoRA Transferability for Video Diffusion Models

Yuchen Wang, Wenliang Zhong, Lichen Bai, zikai zhou, Shitong Shao, Bojun Cheng, Shuo Chen, Shuo Yang, Zeke Xie

Video diffusion models leveraging step distillation or causal distillation have achieved remarkable performance. However, adapting existing LoRAs to these variants remains a critical challenge due to weight space mismatches. We observe that direct application leads to style degradation and structural collapse, yet the underlying mechanisms remain poorly understood. To fill this gap, we delve into the weight space and identify that the incompatibility stems from spectral interference within shared functional clusters defined over singular subspaces. Specifically, our analysis reveals that while both paradigms respect spectral rigidity, they establish conflicting routing pathways that clash through constructive overload or destructive cancellation. To address this issue, we propose Cluster-Aware Spectral Arbitration (CASA), a data-free framework that dynamically arbitrates between safeguarding the target's manifold and restoring LoRA alignment based on spectral density. Extensive experiments demonstrate that CASA effectively mitigates artifacts and revives LoRA functionality. Our code is available at https://github.com/Noahwangyuchen/CASA.

Factorized Scheduling Principle: Learning Interpretable and Transferable Policies via Structured Additive Functions

Hong Je-Gal, Hyun-Suk Lee

Scheduling problems arise from repeatedly selecting one item from a set of candidates based on their states. These problems often reduce to assigning priority scores and choosing the highest-ranked item.

In this work, we propose a factorized scheduling principle (FSP) framework to learn interpretable and transferable scheduling rules. The FSP framework represents system states as condition distributions and decomposes a global scheduling principle into additive univariate and pairwise components with identifiability constraints.

The scheduling principle enables the framework to maintain a simple priority-based structure during deployment. This principle is learned by using a policy-based objective combined with a temporal-difference signal defined on the condition distribution.

Experiments on synthetic and realistic scheduling tasks demonstrate the FSP framework's strong performance, interpretability, and zero-shot generalization across different system scales.

Bayesian Rain Field Reconstruction using Commercial Microwave Links and Diffusion Model Priors
Badr MOUFAD, Albina Ilina, Hai Victor Habi, Salem Lahlou, Yazid Janati, HAGIT MESSER, Eric Moulines
Commercial Microwave Links (CMLs) offer dense spatial coverage for rainfall sensing but produce path-integrated measurements that make accurate ground-level reconstruction challenging. Existing methods typically oversimplify CMLs as point sensors and neglect the physical power-law relating rainfall to signal attenuation, resulting in degraded performance under heterogeneous precipitation. In this work, we view rain field reconstruction as a Bayesian inverse problem with Diffusion Models (DMs) as high-fidelity spatial priors. We show that diffusion models better preserve key rainfall statistics compared to censored Gaussian processes. Framing rainfall estimation as a Bayesian inverse problem with a DM prior enables training-free posterior sampling using a broad family of methods, including Plug-and-Play, Sequential Monte Carlo, and Replica Exchange methods. Experiments on synthetic and real-world datasets demonstrate consistent improvements over established CML-based reconstruction baselines.
****
A Robust Optimization Guided Pruning Framework for Vision and Large Language Models
Gabriel Afriat, Hussein Hazimeh, Dimitris Paparas, Rahul Mazumder
Pruning is a common approach to reduce the memory footprint and inference cost of large vision and language models. As these architectures continue to scale, one-shot pruning methods - i.e. approaches that prune the network without any retraining - have become increasingly attractive. Many popular one-shot pruning methods (e.g., WoodFisher, CAP, SparseGPT, and ALPS) typically optimize a quadratic objective under sparsity constraints. However, in practice, this objective is affected by multiple sources of uncertainty, including noise in the calibration data and variability introduced by algorithmic updates. To address these issues, we introduce RobOP, a robust optimization framework that explicitly accounts for such uncertainties. RobOP is modular and flexible, and can be applied with any existing pruning method through simple modifications motivated by our theoretical framework. We demonstrate that by taking into account uncertainty, RobOP offers improvements over prior pruning approaches. Our framework applies tractably across a range of stylized uncertainty sets, enabling robust one-shot pruning at scale. Our code is available at https://github.com/mazumder-lab/RobOP.
****
Knowing the Unknown: Interpretable Open-World Object Detection via Concept Decomposition Model
Xueqiang Lv, Shizhou Zhang, Yinghui Xing, Di Xu, PENG WANG, Yanning Zhang
Open-world object detection (OWOD) requires incrementally detecting known categories while reliably identifying unknown objects. Existing methods primarily focus on improving unknown recall, yet overlook interpretability, often leading to known–unknown confusion and reduced prediction reliability. This paper aims to make the entire OWOD framework interpretable, enabling the detector to truly “knowing the unknown.” To this end, we propose a concept-driven InterPretable OWOD framework(IPOW) by introducing a Concept Decomposition Model (CDM) for OWOD, which explicitly decomposes the coupled RoI features in Faster R-CNN into discriminative, shared, and background concepts. Discriminative concepts identify the most discriminative features to enlarge the distances between known categories, while shared and background concepts, due to their strong generalization ability, can be readily transferred to detect unknown categories. Leveraging the interpretable framework, we identify that known–unknown confusion arises when unknown objects fall into the discriminative space of known classes. To address this, we propose Concept-Guided Rectification (CGR) to further resolve such confusion. Extensive experiments show that IPOW significantly improves unknown recall while mitigating confusion, and provides
concept-level interpretability for both known and unknown predictions.
****

ALAS: Additive Learnable Alpha-Stable Kernels for Flexible Bayesian Optimization
Weibo Huang, Cheng Hua
Bayesian Optimization is widely used for expensive black-box optimization, yet its success often depends on choosing a kernel that matches the objective’s unknown structure. In this work, we propose ALAS, a flexible Gaussian Process kernel family built from symmetric α-stable spectral components. By learning the stability parameter α, ALAS adapts its effective smoothness from data, capturing both smooth trends and sharp irregularities. We present two parameterizations: ALAS, a single stationary component with joint spectral modulation, and ALAS-Sep, a separable variant that learns dimension-wise tail behavior to improve robustness on approximately decomposable objectives. Experiments on standard benchmarks and real-world surrogates demonstrate strong and robust performance across diverse settings.

The Trojan Knowledge: Bypassing Commercial LLM Guardrails via Harmless Prompt Weaving and Adaptive Tree Search
Rongzhe Wei, Peizhi Niu, Xinjie Shen, Tony Tu, Yifan Li, Ruihan Wu, Eli Chien, Pin-Yu Chen, Olgica Milenkovic, Pan Li
Large language models (LLMs) remain vulnerable to jailbreak attacks that bypass safety guardrails. Existing approaches overwhelmingly operate within the prompt-optimization paradigm; the resulting prompts typically retain malicious semantic signals that modern guardrails are primed to detect. In contrast, we identify a deeper vulnerability stemming from the highly interconnected nature of an LLM’s internal knowledge. This structure allows harmful objectives to be realized by weaving together sequences of benign sub-queries, each of which individually evades detection. To exploit this loophole, we introduce the Correlated Knowledge Attack Agent (CKA-Agent), a dynamic framework that reframes jailbreaking as an adaptive, tree-structured exploration of the target model’s knowledge base. The CKA-Agent issues locally innocuous queries, uses model responses to guide exploration across multiple paths, and ultimately assembles the aggregated information to achieve the original harmful objective. Evaluated across SOTA commercial LLMs, CKA-Agent consistently achieves over 95\% success rates even against strong guardrails, underscoring the severity of this vulnerability and the urgent need for defenses against such knowledge-decomposition attacks. Our codes are available at https://github.com/Graph-COM/CKA-Agent.

Prescriptive Scaling Reveals the Evolution of Language Model Capabilities
Hanlin Zhang, Jikai Jin, Vasilis Syrgkanis, Sham M. Kakade
Machine learning model performance arises from competition and application. For deployment, we consider the prescriptive scaling laws: given a pre-training compute budget, what downstream accuracy is attainable with contemporary post-training practice, and how stable is that mapping as the field evolves? Using large-scale observational evaluations with 5k observational and 2k newly sampled data on model performance, we estimate capability boundaries—high conditional quantiles of benchmark scores as a function of log pre-training FLOPs, via smoothed quantile regression with a monotone, saturating sigmoid parameterization. We validate the temporal reliability by fitting on earlier model generations and evaluating on later releases. Across various tasks, the estimated boundaries are mostly stable, with the exception of math reasoning that exhibits a consistently advancing boundary over time. We then extend our approach to analyze task-dependent saturation and to probe contamination-related shifts on math reasoning tasks. Finally, we introduce an efficient algorithm that recovers near-full-data frontiers using roughly 20% of evaluation budget. Together, our work releases the Proteus-2k, the latest model performance evaluation dataset, and introduces a practical methodology for translating compute budgets into reliable performance expectations and for monitoring when capability boundaries move.
****

MapDream: Task-Driven Map Learning for Vision-Language Navigation
Guoxin Lian, Shuo Wang, Yucheng Wang, Yongcai Wang, Maiyue Chen, Kaihui Wang, Bo Zhang, Zhizhong Su, Deying Li, Zhaoxin Fan

Vision-Language Navigation (VLN) requires agents to follow natural language instructions in partially observed 3D environments, motivating map representations that aggregate spatial context beyond local perception.
However, most existing approaches rely on hand-crafted maps constructed independently of the navigation policy.
We argue that maps should instead be learned representations shaped directly by navigation objectives rather than exhaustive reconstructions.
Based on this insight, we propose MapDream, a map-in-the-loop framework that formulates map construction as autoregressive bird’s-eye-view (BEV) image synthesis.
The framework jointly learns map generation and action prediction, distilling environmental context into a compact three-channel BEV map that preserves only navigation-critical affordances.
Supervised pre-training bootstraps a reliable mapping-to-control interface, while the autoregressive design enables end-to-end joint optimization through reinforcement fine-tuning.
Experiments on R2R-CE and RxR-CE achieve state-of-the-art monocular performance, validating task-driven generative map learning.
****

Sample Margin-Aware Recalibration of Temperature Scaling
Haolan Guo, Linwei Tao, Haoyang Luo, Minjing Dong, Chang Xu
Deep neural networks frequently exhibit overconfidence, undermining reliability in safety-critical applications. Existing adaptive methods rely on indirectly learned proxies of sample difficulty. We establish the logit margin as a direct and principled hardness indicator. We prove that margin constrains the feasible temperature range for a target confidence. Empirically, margin strongly correlates with decision boundary proximity and reveals systematic calibration patterns across difficulty levels. We further identify a fundamental flaw in NLL-based optimization: minimizing NLL can paradoxically worsen calibration. To address this, we introduce Charbonnier-SoftECE, a smooth objective that provably upper-bounds the smooth calibration error (smCE). Building on these insights, we propose SMART (Sample Margin-Aware Recalibration of Temperature), a lightweight method that learns a sample-wise margin-to-temperature mapping guided by our calibration-centric objective. Experiments demonstrate state-of-the-art calibration across CNNs and ViTs on standard, long-tailed, and distribution-shifted benchmarks, with minimal inference-time overhead. Code is available at: https://github.com/Misakaaaaaz/ICML2026-SMART.

Temporal Straightening for Latent Planning
Ying Wang, Oumayma Bounou, Gaoyue Zhou, Randall Balestriero, Tim G. J. Rudner, Yann LeCun, Mengye Ren
Learning good representations is essential for latent planning with world models. While pretrained visual encoders produce strong semantic visual features, they are not tailored to planning and contain information irrelevant---or even detrimental---to planning. Inspired by the perceptual straightening hypothesis in human visual processing, we introduce temporal straightening to improve representation learning for latent planning. Using a curvature regularizer that encourages locally straightened latent trajectories, we jointly learn an encoder and a predictor of a Joint-Embedding Predictive Architecture (JEPA) world model. We show that reducing curvature this way makes the Euclidean distance in latent space a better proxy for the geodesic distance and improves the conditioning of the planning objective. We demonstrate empirically that temporal straightening makes gradient-based planning more stable and yields significantly higher success rates across a suite of goal-reaching tasks. Our code is in https://agenticlearning.ai/temporal-straightening.

Identifiable Markov Switching Models with Instantaneous Effects and Exponential Families
Roel Hulsman, Carles Balsells-Rodas, Sara Magliacane
Temporal systems often exhibit non-stationary behaviour, such as seasonal climat

e variation or glucose fluctuations in patients with type-1 diabetes.
One way to model non-stationarity is through discrete latent *regimes*, *i.e.*, stationary segments of time.
Such systems induce a *Markov Switching Model* (MSM), a class of Hidden Markov Models with autoregressive dependencies among latent regimes and observed variables.
Identifying latent regimes is challenging in the presence of frequent regime switches and nonlinear and non-Gaussian dynamics, particularly when there are *instantaneous effects* between the variables, *e.g.*, due to slow rates of measurements.
In this work, we establish the identifiability of both latent regimes and regime-dependent causal structures under temporal regime dependencies, nonlinear lagged and instantaneous effects, and independent noise from the exponential family.
Our identifiability theory subsumes non-temporal mixtures of causal models.
Furthermore, we introduce $\texttt{FlowMSM}$, a regime detection framework that can be paired with any stationary causal discovery method to recover regime-dependent causal structures.
Experiments on synthetic benchmarks and a financial economics dataset demonstrate the effectiveness of our approach to detect latent regimes and discover causal structures from non-stationary time series.

SPUR: Scale-Partitioned Uncertainty Rectification for Robust UAV-on-UAV Interception
Chenqi Yan, Zhaoyu Zeng, Yifeng Yang, Jundong Zhou, Zhuoyuan Ni, Junqi Wu, Qinying Gu, Xinbing Wang, Nanyang Ye
Robust aerial target detection for autonomous UAV-on-UAV pursuit is severely hindered by continuous scale drift, long-tailed scale imbalance, and flight-induced visual noise, rendering standard empirical risk minimization strategies poorly aligned with real-world deployment. To address these challenges, we propose a scale-aware robust optimization framework that performs group-wise minimax optimization over scale-partitioned data, ensuring balanced robustness across long-, mid-, and close-range engagement regimes. We further introduce an uncertainty-rectified regression loss to suppress noise-driven errors without discarding informative hard examples, complemented by a control-aligned center accuracy penalty that prioritizes the localization precision required for stable flight control. Extensive experiments demonstrate that our method yields substantially improved robustness under visual degradation, with significantly slower decay in detection mAP and center-point accuracy compared to baselines. Validated through both photorealistic simulations and real-world flight tests, our system achieves **real-time performance of 120 FPS** on an embedded NVIDIA Orin NX platform, confirming its practical efficacy for high-speed interception.

Dual Mechanisms of Value Expression: Intrinsic vs. Prompted Values in Large Language Models
Jongwook Han, Jongwon Lim, Injin Kong, Yohan Jo
Large language models can express values in two main ways: (1) $\textit{intrinsic}$ expression, reflecting the model's inherent values learned during training, and (2) $\textit{prompted}$ expression, elicited by explicit prompts. Given their widespread use in value alignment, it is paramount to clearly understand their underlying mechanisms, particularly whether they mostly overlap (as one might expect) or rely on distinct mechanisms. We analyze this largely understudied problem at the mechanistic level using two approaches: (1) $\textit{value vectors}$, feature directions representing value mechanisms extracted from the residual stream, and (2) $\textit{value neurons}$, MLP neurons that contribute to value vectors.
We demonstrate that intrinsic and prompted value mechanisms partly share common components crucial for inducing value expression, generalizing across languages and reconstructing theoretical inter-value correlations in the model's internal representations. Yet, each mechanism also possesses unique components that fulfill distinct roles. In particular, the intrinsic mechanism activates in more dive

rse value-related scenarios and promotes response diversity, whereas the prompte d mechanism strengthens instruction compliance, taking effect even in distant ta sks like jailbreaking.

Advancing SVD-based LLM Compression via Layer-Wise Error Model Search
Moritz Thoma, Maximilian Groezinger, Maximilian Forstenhäusler, Emad Aghajanzade h, Manoj Rohit Vemparala, Christos Anagnostopoulos, Pierpaolo Mori, Nael Fasfous , Alexander Frickenstein, Daniel Mueller-Gritschneder, Ulf Schlichtmann
Low-rank SVD-based compression offers a powerful strategy to reduce the computat ional costs of LLMs. However, existing methods face two key limitations: (i) glo bal rank allocation, where uncalibrated error proxies fail to capture complex er ror propagation, and (ii) decomposition quality, where Fisher-based estimators s uffer from severe rank collapse. In this work, we address these limitations by i ntroducing Layer-wise Error Modeling Search (LEMS) and KFAC-SVD. LEMS advances r ank allocation by introducing a layer-wise error surrogate that integrates local and global layer importance alongside a propagation bias, enabling effective gl obal rank allocation via an ILP formulation. KFAC-SVD improves decomposition qua lity by utilizing token-wise statistics, mitigating the rank deficiency observed in prior Fisher-based SVD approaches. Across Mistral, Qwen3, and Llama3 model f amilies, we show that LEMS consistently outperforms existing search strategies, delivering significant zero-shot accuracy gains of up to 4.8 p.p. that generaliz e to model sizes of 70B parameters, while KFAC-SVD achieves an average perplexit y improvement of 15%. The Unlearnability Phenomenon in RLVR for Language Models
Yulin Chen, He He, Chen Zhao
Reinforcement Learning with Verifiable Reward (RLVR) has proven effective in imp roving Large Language Model's (LLM) reasoning ability. However, the learning dyn amics of RLVR remain underexplored.
In this paper, we reveal a counterintuitive phenomenon: among hard examples that the model initially struggles with, a substantial subset remains unlearnable ev en when correct rollouts are present.
To understand the phenomenon, we first demonstrate that existing optimization an d sampling techniques fail to resolve unlearnability.
With cross-example gradient analysis, we show that unlearnable examples have fun damental representation issue, characterized by low gradient similarity with the rest of the examples and ungeneralizable reasoning patterns.
We further show that representation flaws are difficult to mitigate in RL, as da ta augmentation does not improve gradient similarity.
Our study provides the first systematic characterization of unlearnable data in RLVR training and reveals fundamental limitations in current RL approaches for r easoning tasks.

Reasoning Can Be Restored by Correcting a Few Decision Tokens
Changshuo Shen, Leheng Sheng, Yuxin Chen, Xiang Wang, An Zhang
Large reasoning models (LRMs) substantially outperform their base LLM counterpar ts on challenging reasoning benchmarks, yet it remains poorly understood where b ase models go wrong during token-by-token generation and how to narrow this gap efficiently. We study the base–reasoning gap by quantifying token-level distribu tional disagreement between a base model and a stronger reasoning model using li kelihood-based divergences. Across benchmarks, we find that the reasoning advant age is highly sparse and concentrates on a small set of early, planning-related decision tokens. For instance, on Qwen3-0.6B, only $\sim$8\% of generated tokens account for the salient disagreement; these tokens concentrate early in the res ponse, are strongly enriched in planning-related decisions ($17\times$), and coi ncide with high base-model uncertainty—suggesting that base models fail mainly a t early planning points that steer the subsequent reasoning trajectory. Building on these findings, we propose disagreement-guided token intervention, a simple inference-time delegation scheme that performs a one-token takeover by the reaso ning model only at high-disagreement positions and immediately switches back to

the base model. With a small intervention budget, this sparse delegation substantially recovers and can even surpass the performance of a same-size reasoning model on challenging reasoning tasks. Code is available at \url{https://github.com/AlphaLab-USTC/RRTokenIntervention}.

E-VAds: An E-commerce Short Videos Understanding Benchmark for MLLMs
Xianjie Liu, Yiman Hu, Liang Wu, Ping Hu, Yixiong Zou, Jian Xu, Bo Zheng
E-commerce short videos represent a high-revenue segment of the online video industry characterized by a goal-driven format and dense multi-modal signals. Current models often struggle with these videos because existing benchmarks focus primarily on general-purpose tasks and neglect the reasoning of commercial intent. In this work, we first propose a **multi-modal information density assessment framework** to quantify the complexity of this domain. Our evaluation reveals that e-commerce content exhibits substantially higher density across visual, audio, and textual modalities compared to mainstream datasets, establishing a more challenging frontier for video understanding.
To address this gap, we introduce **E-commerce Video Ads Benchmark**, which is the first benchmark specifically designed for e-commerce short video understanding. We curated 3,961 high-quality videos from Taobao covering a wide range of product categories and used a multi-agent system to generate 19,785 open-ended Q\&A pairs. These questions are organized into Perception and Cognition and Reasoning, which consist of five distinct tasks. Finally, we develop **E-VAds-R1**, an RL-based reasoning model featuring a multi-grained reward design called **MG-GRPO**. This strategy provides smooth guidance for early exploration while creating a non-linear incentive for expert-level precision. Experimental results demonstrate that E-VAds-R1 achieves a 109.2\% performance gain in commercial intent reasoning with only a few hundred training samples. Data is available at https://github.com/TaobaoTmall-AlgorithmProducts/E-VAds_Benchmark.

Implicit Intelligence - Evaluating Agents on What Users Don’t Say
Ved Sirdeshmukh, Marc Wetter
Real-world requests to AI agents are fundamentally underspecified. Natural human communication relies on shared context and unstated constraints that speakers expect listeners to infer. Current agentic benchmarks test explicit instruction-following but fail to evaluate whether agents can reason about implicit requirements spanning accessibility needs, privacy boundaries, catastrophic risks, and contextual constraints. We present **Implicit Intelligence**, an evaluation framework testing whether AI agents can move beyond prompt-following to become genuine goal-fulfillers, paired with **Agent-as-a-World (AaW)**, a harness where interactive worlds are defined in human-readable YAML files and simulated by language models. Our scenarios feature apparent simplicity in user requests, hidden complexity in correct solutions, and discoverability of constraints through environmental exploration. Evaluating 16 frontier and open-weight models across 205 scenarios, we find that even the best-performing model achieves only 48.3% scenario pass rate, revealing substantial room for improvement in bridging the gap between literal instruction-following and human-like contextual reasoning.
****
Model-Based Diffusion Sampling for Predictive Control in Offline Decision Making
Haldun Balim, Na Li, Yilun Du
Offline decision-making via diffusion models often produces trajectories that are misaligned with system dynamics, limiting their reliability for control. We propose *Model Predictive Diffuser* (MPDiffuser), a compositional diffusion framework that combines a diffusion planner with a dynamics diffusion model to generate task-aligned and dynamically plausible trajectories. MPDiffuser interleaves planner and dynamics updates during sampling, progressively correcting feasibility while preserving task intent. A lightweight ranking module then selects trajectories that best satisfy task objectives. The compositional design improves sample efficiency and adaptability by enabling the dynamics model to leverage diverse and previously unseen data independently of the planner. Empirically, we demonstrate consistent improvements over prior diffusion-based methods on unconstraine

d (D4RL) and constrained (DSRL) benchmarks, and validate practicality through de
ployment on a real quadrupedal robot.

On the Variability of Concept Activation Vectors
Julia Wenkmann, Damien Garreau
One of the most pressing challenges in artificial intelligence is to make models
 more transparent to their users.
Recently, explainable artificial intelligence has come up with numerous methods
to tackle this challenge.
A promising avenue is to use concept-based explanations, that is, high-level con
cepts instead of plain feature importance scores.
Among this class of methods, Concept Activation Vectors (CAVs, Kim et al., 2018)
 stand out as one of the main protagonists.
One interesting aspect of CAVs is that their computation requires sampling rando
m examples from the train set.
Therefore, the actual vectors obtained may vary depending on the randomness of t
his sampling.
In this paper, we propose a fine-grained theoretical analysis of CAV constructio
n in order to quantify their variability.
Our results, confirmed by experiments on several real-life datasets of four diff
erent modalities, point to an universal result: the variance of CAVs declines ro
ughly as $1/N$, where N is the number of random examples.
Based on this, we give practical recommendations for a resource-efficient applic
ation of the method.

Learnability-Informed Fine-Tuning of Diffusion Language Models
Shubham Parashar, Atharv Chagi, Jacob Helwig, Lakshmi Jotsna Madhavarapu, Sushil
 Vemuri, James Caverlee, Dileep Kalathil, Shuiwang Ji
We aim to improve the reasoning capabilities of diffusion language models (DLMs)
. While SFT is a popular post-training recipe for autoregressive models, its use
 in DLMs faces challenges and can even hurt performance, though the underlying c
auses remain understudied. Our analysis reveals that vanilla SFT overlooks learn
ability, namely, *what* and *when* tokens are learned. Specifically, rare tokens
 are difficult to learn when most of the input is masked, whereas it is straight
forward and thus of little value to learn common
tokens when most of the input is unmasked. Motivated by our analysis, we propose
 LIFT, an efficient SFT-based post-training algorithm for
DLMs. LIFT learns easy tokens when most of the input is masked and hard tokens w
hen more context is available, thereby aligning training with the information av
ailable at different diffusion time steps. Our results show that LIFT outperform
s existing SFT baselines across six reasoning benchmarks, achieving up to a 3x r
elative gain on AIME’24 and AIME’25. Our code is publicly available at https://g
ithub.com/divelab/LIFT.

DeepBlip: Estimating Conditional Average Treatment Effects Over Time
Haorui Ma, Dennis Frauen, Stefan Feuerriegel
Structural nested mean models (SNMMs) are a principled approach to estimate the
treatment effects over time. A particular strength of SNMMs is to break the join
t effect of treatment sequences over time into localized, time-specific ``blip e
ffects''. This decomposition promotes interpretability through the incremental e
ffects and enables the efficient offline evaluation of optimal treatment policie
s without re-computation. However, neural frameworks for SNMMs are lacking, as t
heir inherently sequential g-estimation scheme prevents end-to-end, gradient-bas
ed training. Here, we propose DeepBlip, the first neural framework for SNMMs, w
hich overcomes this limitation with a novel double optimization trick to enable
simultaneous learning of all blip functions. Our DeepBlip seamlessly integrates
sequential neural networks like LSTMs or transformers to capture complex tempora
l dependencies. By design, our method correctly adjusts for time-varying confoun
ding to produce unbiased estimates, and its Neyman-orthogonal loss function ensu
res robustness to nuisance model misspecification. Finally, we evaluate our Deep

Blip across various clinical datasets, where it achieves state-of-the-art performance.

Inference Time Optimization with Confidence Dynamics
Yu Wang, Minghao Liu, Jiayun Wang, Jinrui Huang, Ankit Shah, Wei Wei
Inference time optimization techniques, such as repeated sampling, have significantly advanced the reasoning capabilities of Large Language Models (LLMs). However, the critical role of model uncertainty remains largely underexplored in these optimization strategies. In this paper, we investigate the dynamics of confidence along reasoning trajectories and for first time reveal a surprising and unique pattern: correct answer traces tend to exhibit confidence improvement over time (positive confidence gain), while incorrect traces show attenuated or declining confidence as reasoning proceeds. Based on this observation, we propose Confidence Dynamic Gain (CDG) based voting, which incorporates how the confidence trajectory of the response evolves along the reasoning chain. Experiments across four open-source architectures (DeepSeek-R1, gpt-oss, Gemma-3, Qwen-QwQ) on the AIME24/25, HMMT25, and BRUMO25 benchmarks demonstrate that CDG yields a significant performance boost over baselines. These results demonstrate that our method provides a robust discriminative signal for improving answer selection in LLM reasoning. We also provide theoretical insights for this phenomenon. Code will be released at https://github.com/Accenture/CDG.git.

MemoryBench: A Benchmark for Memory and Continual Learning in LLM Systems
Qingyao Ai, Yichen Tang, Changyue Wang, Jianming Long, Weihang Su, Yiqun LIU
Scaling up data, parameters, and test-time computation has been the mainstream methods to improve LLM systems (LLMsys), but their upper bounds are almost reached due to the gradual depletion of high-quality data and marginal gains obtained from larger computational resource consumption. Inspired by the abilities of human and traditional AI systems in learning from practice, constructing memory and continual learning frameworks for LLMsys has become an important and popular research direction in recent literature. Yet, existing benchmarks for LLM memory often focus on evaluating the system on homogeneous reading comprehension tasks with long-form inputs rather than testing their abilities to learn from accumulated user feedback in service time. Therefore, we propose a user feedback simulation framework and a comprehensive benchmark covering multiple domains, languages, and types of tasks to evaluate the continual learning abilities of LLMsys. Experiments show that the effectiveness and efficiency of state-of-the-art baselines are far from satisfying, and we hope this benchmark could pave the way for future studies on LLM memory and optimization algorithms.

GameDevBench: Evaluating Agentic Capabilities Through Game Development
Wayne Chi, Yixiong Fang, Arnav Yayavaram, Siddharth Yayavaram, Seth Karten, Qiuhong Anna Wei, Runkun Chen, Alexander Wang, Valerie Chen, Ameet Talwalkar, Chris Donahue
Despite rapid progress on coding agents, progress on their multimodal counterparts has lagged behind.
A key challenge is the scarcity of evaluation testbeds that combine the complexity of software development with the need for deep multimodal understanding.
In game development, agents must navigate large, dense codebases while manipulating intrinsically multimodal assets such as shaders, sprites, and animations within a visual game scene.
We present GameDevBench, the first benchmark for evaluating agents on game development tasks.
GameDevBench consists of 333 tasks derived from web and video tutorials.
Tasks require significant multimodal understanding and are complex---the average solution requires over three times the lines of code and file changes compared to prior software development benchmarks.
Agents struggle with game development, with the best agent and method solving only 53.8% of tasks.
We find a strong correlation between perceived task difficulty and multimodal co

mplexity, with average success rate dropping from 51.4% on gameplay-oriented tasks to 33.0% on 2D graphics tasks.
To improve multimodal capability, we introduce two simple image and video-based feedback mechanisms for agents.
Despite their simplicity, these methods consistently improve performance, increasing GPT-5.4's performance from 41.1% to 52.0% when given visual feedback.

Causal Flow Q-Learning for Robust Offline Reinforcement Learning
Mingxuan Li, Junzhe Zhang, Elias Bareinboim
Expressive policies based on flow-matching have been successfully applied in reinforcement learning (RL) more recently due to their ability to model complex action distributions from offline data. These algorithms build on standard policy gradients, which assume that there is no unmeasured confounding in the data. However, this condition does not necessarily hold for pixel-based demonstrations when a mismatch exists between the demonstrator's and the learner's sensory capabilities, leading to implicit confounding biases in offline data. We address the challenge by investigating the problem of confounded observations in offline RL from a causal perspective. We develop a novel causal offline RL objective that optimizes policies' worst-case performance that may arise due to confounding biases. Based on this new objective, we introduce a practical implementation that learns expressive flow-matching policies from confounded demonstrations, employing a deep discriminator to assess the discrepancy between the target policy and the nominal behavioral policy. Experiments across 25 pixel-based tasks demonstrate that our proposed confounding-robust augmentation procedure achieves a success rate 120\% that of confounding-unaware, state-of-the-art offline RL methods.

From Muon to Gluon: Bridging Theory and Practice of LMO-based Optimizers for LLMs
Artem Riabinin, Egor Shulgin, Kaja Gruntkowska, Peter Richtárik
Recent developments in deep learning optimization have brought about radically new algorithms based on the Linear Minimization Oracle (LMO) framework, such as Muon (Jordan et al., 2024b) and Scion (Pethick et al., 2025b). After over a decade of Adam’s dominance, these LMO-based methods are emerging as viable replacements, offering several practical advantages such as improved memory efficiency, better hyperparameter transferability, and most importantly, superior empirical performance on large-scale tasks, including LLM training. However, a significant gap remains between their practical use and our current theoretical understanding: prior analyses (1) overlook the layer-wise LMO application of these optimizers in practice, and (2) rely on an unrealistic smoothness assumption, leading to impractically small stepsizes. To address both, we propose a new LMO-based framework called Gluon, capturing prior theoretically analyzed methods as special cases, and introduce a new refined generalized smoothness model that captures the layer-wise geometry of neural networks, matches the layer-wise practical implementation of Muon and Scion, and leads to state-of-the-art convergence guarantees. Our experiments with NanoGPT and CNN confirm that our assumption holds along the optimization trajectory, ultimately narrowing the gap between theory and practice.

Leveraging Evidence Priors for Robust Prompt Learning under Noisy Supervision in Vision-Language Models
Junnan Zou, Zhu Teng, Wei Zhang, Ming He, Jianping Fan
Prompt learning for vision-language models (VLMs) often suffers from performance degradation when adapting to downstream tasks with noisy labels. Existing methods that rely on filtering or reconstructing supervision can propagate errors, leading to sharp performance drops. We observe that pre-trained embeddings are resilient to label noise, offering stable references despite limited adaptation. Based on this insight, we propose Evidence-Prompt, a framework built on the evidence prior that enhances prompt learning by integrating stable pre-trained knowledge. We treat prompt learning as a Bayesian reasoning task, where credibility is derived from both supervision-agnostic and supervision-conditioned evidence. Thi

s framework effectively combines these sources to infer robust training targets under noisy conditions, enabling stable learning even with high noise levels. Extensive experiments on eight benchmarks with both synthetic and real-world noisy labels demonstrate that our method flattens the accuracy–noise curve and consistently outperforms SOTA methods, with notable gains on OxfordPets dataset at a 75\% noise rate (+36.6\% under Asym and +14.4\% under Sym). Additionally, transferability experiments reveal that incorporating our evidence prior into other SOTA methods results in accuracy improvements ranging from 2.6\% to 15.66\%.

Efficient LLM Moderation with Multi-Layer Latent Prototypes
Maciej Chrabaszcz, Filip Szatkowski, Bartosz Wójcik, Jan Dubi■ski, Tomasz Trzcinski, Sebastian Cygert
Although modern LLMs are aligned with human
values during post-training, robust moderation
remains essential to prevent harmful outputs at deployment time. Existing approaches suffer from
performance-efficiency trade-offs and are difficult to customize to user-specific requirements.
Motivated by this gap, we introduce Multi-Layer
Prototype Moderator (MLPM), a lightweight and
highly customizable input moderation tool. We
propose leveraging prototypes of intermediate representations across multiple layers to improve
moderation quality while maintaining high efficiency. By design, our method adds negligible
overhead to the generation pipeline and can be
seamlessly applied to any model. MLPM achieves
state-of-the-art performance on diverse moderation benchmarks and demonstrates strong scalability across model families of various sizes. Moreover, we show that it integrates smoothly into end-to-end moderation pipelines and further improves
response safety when combined with output moderation techniques. Overall, our work provides a
practical and adaptable solution for safe, robust,
and efficient LLM deployment.
****
StitchCUDA: An Automated Multi-Agents End-to-End GPU Programing Framework with Rubric-based Agentic Reinforcement Learning
Shiyang Li, Zijian Zhang, Winson Chen, Yuebo Luo, Mingyi Hong, Caiwen Ding
Modern machine learning (ML) workloads increasingly rely on GPUs, yet achieving high end-to-end performance remains challenging due to dependencies on both GPU kernel efficiency and host-side settings. Although LLM-based methods show promise on automated GPU kernel generation, prior works mainly focus on single-kernel optimization and do not extend to end-to-end programs, hindering practical deployment.

To address the challenge, in this work, we propose \textsc{StitchCUDA}, a multi-agent framework for end-to-end GPU program generation, with three specialized agents: a \textit{Planner} to orchestrate whole system design, a \textit{Coder} dedicated to implementing it step-by-step, and a \textit{Verifier} for correctness check and performance profiling using Nsys/NCU. To fundamentally improve the \textit{Coder}'s ability in end-to-end GPU programming, \textsc{StitchCUDA} integrates rubric-based agentic reinforcement learning over two atomic skills, task-to-code generation and feedback-driven code optimization, with combined rubric reward and rule-based reward from real executions. Therefore, the \textit{Coder} learns how to implement advanced CUDA programming techniques (e.g., custom kernel fusion, cublas epilogue), and we also effectively prevent \textit{Coder}'s reward hacking (e.g., just copy PyTorch code or hardcoding output) during benchmarking. Experiments on KernelBench show that \textsc{StitchCUDA} achieves nearly 100\% success rate on end-to-end GPU programming tasks, with 1.72$\times$ better sp

eedup over the multi-agent baseline and 2.73$\times$ than the RL model baselines
.
****
Learning 3D-Gaussian Simulators from RGB Videos
Mikel Zhobro, Andreas René Geist, Georg Martius
Realistic simulation is critical for applications ranging from robotics to anima
tion. Video generation models have emerged as a way to capture real-world physic
s from data, but they often face challenges in maintaining spatial consistency a
nd object permanence, relying on memory mechanisms to compensate. As a complemen
tary direction, we present 3DGSim, a learned 3D simulator that directly learns p
hysical interactions from multi-view RGB videos. 3DGSim adopts MVSplat to learn
a latent particle-based representation of 3D scenes, a Point Transformer for the
particle dynamics, a Temporal Merging module for consistent temporal aggregatio
n, and Gaussian Splatting to produce novel view renderings. By jointly training
inverse rendering and dynamics forecasting, 3DGSim embeds physical properties in
to point-wise latent features. This enables the model to capture diverse behavio
rs, from rigid and elastic to cloth-like dynamics and boundary conditions (e.g.,
fixed cloth corners), while producing realistic lighting effects. We show that
3DGSim can generate physically plausible results even in out of distribution cas
es, e.g. ground removal or multi-object interactions, despite being trained only
on single-body collisions.

Lookahead Sample Reward Guidance for Test-Time Scaling of Diffusion Models
Yeongmin Kim, Donghyeok Shin, Byeonghu Na, Minsang Park, Richard Lee Kim, Il-chu
l Moon
Diffusion models have demonstrated strong generative performance; however, gener
ated samples often fail to fully align with human intent. This paper studies an
efficient test-time scaling method for sampling from regions with higher human-a
ligned reward values. Existing methods for computing the expected future reward
(EFR) face important limitations: backward rollout incurs prohibitively high sam
pling costs, while Tweedie-based approaches, including Sequential Monte Carlo an
d gradient guidance, suffer from bias and inherent sampling issues. We show that
the EFR at any $\mathbf{x}_t$ can be computed using only marginal samples from
a pre-trained diffusion model, enabling closed-form reward guidance without neur
al backpropagation. To further improve efficiency, we introduce a few-step looka
head sampling and an accurate solver that guides particles toward high-reward lo
okahead samples. We refer to this sampling scheme as LiDAR sampling. LiDAR achie
ves the same GenEval performance as the latest gradient guidance method for SDXL
with a 9.5× speedup. We release the code at https://github.com/aailab-kaist/Dif
fusion-LiDAR-Sampling.

Adaptive Recurrent Message Passing for Test Time Computing on Graphs
Junshu Sun, Wanxing Chang, Qingming Huang, Shuhui Wang
Pre-trained foundation models have demonstrated remarkable success in many domai
ns, enabling a unified backbone to generalize across diverse downstream tasks. H
owever, extending this paradigm to graph learning remains challenging due to the
intrinsic mismatch between graph data and fixed architectural designs. In this
work, we show that this limitation can be overcome via recurrent graph models. T
o achieve this, we conduct a systematic theoretical analysis, rigorously derivin
g step dependence as a necessary and sufficient condition for an adaptively conv
ergent recurrent process. Building on this foundation, we propose AdaR, an Adapt
ive Recurrent graph model, empowering flexible test-time computing on various do
wnstream tasks without changing model parameters. To enable adaptive inference,
AdaR explicitly encodes normalized step information and representation–target re
lations into the recurrent updates. To ensure convergence of the recurrent proce
ss, AdaR employs gradient-based supervision signals that guide representation up
dates throughout the recurrence. Empirical results demonstrate that AdaR consist
ently outperforms strong baselines in both inductive and transductive settings.

Time-Conditioned Foreseeing: An EHR-Specific Foundation Model for Irregular Dyna

mics and Calendrical Time
Bong Gyun Kang, Junyong Ahn, Hyeongrok Han, Sungroh Yoon
Electronic Health Records (EHRs) possess unique characteristics distinct from natural language, yet existing EHR foundation models often rely on suboptimal NLP-based approaches. We propose a pretraining method tailored to EHRs' distinct features. First, we introduce Pathology-Focused Binning, a density-based quantization strategy that prioritizes clinically significant numerical ranges over usual values. Second, to jointly capture both the exact timing of clinical events and the relative intervals between them, we propose Dual-Calendar Rotary Positional Embedding (RoPE), which encodes absolute and relative temporal signals. Third, we introduce the Time-Conditioned Foreseeing (TCF) objective, aligning with clinical treatment planning to forecast events across multiple temporal horizons by explicitly modeling event timing. Our approach establishes a temporal generative EHR model that outperforms existing foundation models on eleven diverse downstream tasks—achieving up to a 54% improvement in AUPRC—and enables the generation of realistic, temporally consistent patient trajectories. Code is available at https://github.com/Pusheen-cat/TCF_PFM.

ADHD Disease Detection Based on Short- and Long-Term Brain Function Encoding and Memory Graph Network
Dongxun Jiang, Borui Jia, Yuxuan Wang, Dongdong Zhang
Graph-based attention deficit hyperactivity disorder (ADHD) detection methods have been extensively studied, but comparatively less attention has been paid to short-term brain functional reorganization. In this paper, we propose an ADHD disease detection model based on short- and long-term brain function encoding and memory graph network. We first exploit a novel brain map sequence construction method based on short-term windows to extract short-term brain function features. Then, we design a short-term state and temporal dependency encoder to characterize short-term sequence patterns of brain function. Furthermore, a brain function memory is introduced to capture the association of brain activity patterns and historical sequence patterns. Concurrently, GNN-based long-term brain function feature extraction network is used to extract brain structure features, which are fused with short-term features for ADHD detection. Experimental validation on the publicly available neuroimaging datasets ADHD-200 and OpenNeuro-ds002424 demonstrates the superior performance of our model in brain disorder detection.
****
3DGS-HPC: Distractor-free 3D Gaussian Splatting with Hybrid Patch-wise Classification
Jiahao Chen, Yipeng Qin, Ganlong Zhao, Xin Li, Wenping Wang, Guanbin Li
3D Gaussian Splatting (3DGS) has demonstrated remarkable performance in novel view synthesis and 3D scene reconstruction, but its quality often degrades in real-world environments due to transient distractors, such as moving objects and varying shadows. Existing methods commonly introduce semantic priors from pre-trained vision models either to group pixels into coherent regions or to define perceptual error metrics. However, semantic grouping is often misaligned with the binary static/transient distinction, while perceptual features can be fragile under appearance perturbations introduced during 3DGS optimization. We propose 3DGS-HPC, a framework that addresses these issues by combining two complementary principles: a patch-wise classification strategy that leverages local spatial consistency for robust region-level decisions, and a hybrid classification metric that adaptively integrates photometric and perceptual cues for more reliable separation. Extensive experiments demonstrate the superiority and robustness of our method in mitigating distractors to improve 3DGS-based novel view synthesis. Our project page is https://cnhaox.github.io/3DGS-HPC/.

PnP-Corrector: A Universal Correction Framework for Coupled Spatiotemporal Forecasting
Hao Wu, Fan Xu, Yuxu Lu, Penghao Zhao, Fan Zhang, Hao Jia, Yuxuan Liang, Ruijian Gou, Qingsong Wen, Xian Wu, Xiaomeng Huang, Yuan Gao
Coupled spatiotemporal forecasting is important for predicting the future evolut

ion of multiple interacting dynamical systems, such as in climate models.
However, existing methods are severely constrained by the persistent bottleneck of compounding errors.
In coupled systems, errors from each subsystem simulator propagate and amplify one another, a phenomenon we term Reciprocal Error Amplification leading to a rapid collapse of long-range predictions.
To address this challenge, we propose a universal framework called PnP-Corrector (Plug-and-Play Corrector).
The core idea of our framework is to decouple the physical simulation from the error correction process: it freezes pre-trained physics simulation engines and exclusively trains a correction agent to proactively counteract the systematic biases emerging from the coupled system.
Furthermore, we design an efficient predictive model architecture, DSLCast, to serve as the backbone of this framework.
Extensive experiments demonstrate that our method significantly enhances the long-term stability and accuracy of coupled forecasting systems.
For instance, in the challenging task of a 300-day global ocean-atmosphere coupled forecast, our PnP-Corrector framework reduces the prediction error of the baseline model by 28% and surpasses state-of-the-art models on several key metrics.

Geometric Flow Grounding: A Unified Manifold Decoupling Framework for Dynamics Discovery and Verification

Chang Yu, Yuxuan Luo, Yixuan Du, Yuqing Zhou, Siyuan Li, Jingbo Zhou, jiawei jiang, Zhen Lei, Stan Z. Li

Modeling complex dynamics from observational data is fundamental to scientific discovery and artificial intelligence. However, existing approaches are often plagued by the entanglement of static state representations and instantaneous motion, leading to accumulated errors and off-manifold hallucinations where predicted trajectories violate intrinsic geometric constraints. To address this, we propose Geometric Flow Grounding, a unified framework that enforces dynamic evolution strictly along the tangent bundle of the learned data manifold via a differentiable Neural Tangent Projection Layer. By geometrically decoupling state representation from tangential dynamics, our method generalizes across diverse data regimes. In scientific discovery, GFG reduces numerical aliasing and improves long-horizon stability in sparse dynamical systems, while recovering interpretable gene regulatory motifs from single-cell data. For trustworthy AI, the projection residual provides a zero-shot metric for deepfake video detection by revealing inconsistencies with the implicit flow of pre-trained world models. Our results establish manifold-constrained projection as a universal operator for both discovering natural laws and verifying synthetic content. Code will be available at \url{https://github.com/yuchang97/GFG-public}

Plug-and-Play Guidance for Discrete Diffusion Models via Gradient-Informed Logit Correction

Hongkun Dou, Zike Chen, Fengji Li, Hongjue Li, Yue Deng

Controllable generation with discrete diffusion models is often hindered by high computational overhead or the need for retraining. In this paper, we present Gradient-Informed Logit Correction (GILC), a plug-and-play framework that efficiently estimates guidance signals by repurposing the pretrained denoising network as a variational proxy. To circumvent the gradient instability inherent in high-dimensional discrete spaces, we introduce a Jacobian-free mechanism that directly corrects the clean prediction logits, facilitating stable and effective guidance. Our method accommodates both differentiable and non-differentiable reward functions. Extensive experiments across DNA, protein sequence, and molecular generation tasks demonstrate that GILC achieves state-of-the-art performance without additional training, frequently outperforming fine-tuning approaches.

Generative Modeling of Irregular Time Series via SDE-Induced Continuous-Discrete Variational Inference

Zexin Yuan, Qinliang Su, Junxi Xiao
Irregular time series arise ubiquitously in real-world systems, where observations are sparse, asynchronous, and governed by underlying continuous-time dynamics. Existing continuous–discrete state-space models typically rely on path-based variational inference, which is computationally expensive or constrained by restrictive posterior assumptions. We propose SDEVI, a novel framework that performs variational inference directly on the joint distribution over discrete-time observations, while guaranteeing consistency with an underlying continuous process governed by a Stochastic Differential Equation(SDE). SDEVI employs a variational posterior induced by linear time-varying SDEs as a scalable inference backbone. To enable intricate dynamics modeling for real-world data, we introduce non-linear-SDE-induced variational inference and generalize our framework to the complex domain. Extensive experiments across healthcare, physics, climate, and IoT benchmarks demonstrate state-of-the-art performance on interpolation, extrapolation, regression, and classification tasks.

CiteGuard: Conformal False-Discovery Control for Faithful Retrieval-Augmented Generation
Xiangyu Jiang
Large language models increasingly rely on retrieval-augmented generation (RAG) to ground responses in external corpora. Yet, even with strong retrievers, generated statements can remain unsupported, and the resulting citations are often not reliable indicators of evidence. We introduce CiteGuard, a RAG decoding layer that treats sentence-level factuality as a multiple-testing problem and combines conformal calibration with false-discovery-rate control. CiteGuard converts claim–evidence scores into p-values for the null hypothesis "unsupported" and uses BH/BY procedures to decide which claims to keep (with citations) and which to abstain on. On FEVER and Natural Questions, CiteGuard reduces the false-discovery rate among accepted claims from 28–31% (vanilla RAG) to below 10% at α=0.10, while retaining 86–92% of supported claims. This yields a user-controlled risk budget: practitioners can trade off faithfulness and coverage via α, with finite-sample guarantees under standard exchangeability assumptions.

MAST: Motif-Augmented Diffusion with Search Tree for Spectroscopic Molecular Structure Elucidation
Chenghao Jia, Mengdi Liu, Hong Chang, Shiguang Shan, Xilin CHEN
Elucidating molecular structures from spectra is a foundational problem in chemical and materials characterization, yet remains challenging due to spectral ambiguity and the vast molecular space. Although recent diffusion-based generators show strong promise for spectra-conditioned elucidation, existing methods struggle to learn robust spectra-structure relationships from limited paired data when relying solely on global spectral representation. Moreover, the repeated full sampling inference strategy incurs substantial computation overhead. To address these limitations, we propose MAST, a Motif-Augmented diffusion framework with Search Tree, for joint 2D-3D spectroscopic molecular structure elucidation. MAST introduces explicit, interpretable motif priors as intermediate evidences throughout denoising, reducing conditional ambiguity and facilitating spectra-conditioned optimization. We further cast diffusion sampling as reward-guided tree search to prioritize high-reward denoising trajectories, yielding a compact set of spectra-consistent candidates under limited budgets. On the QM9S multi-spectra benchmark, MAST achieves 94.89% exact recovery and improves 3D fidelity, while preserving high chemical validity and stability. Code is available at https://github.com/Jia040223/MAST.

Agora: Toward Autonomous Bug Detection in Production-Level Consensus Protocols with LLM Agents
Xiang Liu, Sa Song, Zhaowei Zhang, Huiying Lan, Jason Zeng, Ming Wu, Michael Heinrich, Sun Yong, Ceyao Zhang
Consensus protocols form the backbone of distributed systems and blockchains, where implementation bugs can cause data corruption and financial losses. While LL

M-based approaches show promise in code analysis, they struggle with deep protoc
ol-level logic bugs involving complex state-dependent behaviors across multiple
execution stages. We present Agora, a domain-aware multi-agent framework that in
tegrates hypothesis-driven testing with LLM capabilities for systematic protocol
verification. Agora employs specialized agents that collaboratively explore pro
tocol state spaces, synthesize attack scenarios using domain-specific constraint
s, and validate findings through iterative refinement. This explicit role separa
tion enables reasoning about global protocol invariants beyond single-function c
ode analysis. We evaluate Agora on four consensus implementations (Raft, EPaxos,
HotStuff, BullShark) using four state-of-the-art LLMs. Agora discovers 15 previ
ously unknown protocol-level logic bugs that violate safety properties, while ex
isting LLM-based agents fail to detect any such protocol-level logic bugs. Our r
esults demonstrate that domain-aware multi-agent collaboration is essential for
detecting deep logic bugs in complex protocols.

Certified Circuits: Stability Guarantees for Mechanistic Circuits
Alaa Anani, Tobias Lorenz, Bernt Schiele, Mario Fritz, Jonas Fischer
Understanding *how* neural networks arrive at their predictions is essential for
debugging, auditing, and deployment. Mechanistic interpretability pursues this
goal by identifying *circuits*—minimal subnetworks responsible for specific beha
viors. However, existing circuit discovery methods are brittle: circuits depend
strongly on the chosen concept dataset and often fail to transfer out-of-distrib
ution, raising doubts whether they capture the concept or merely dataset-specifi
c artifacts. We introduce *Certified Circuits*, which provide provable stability
guarantees for circuit discovery. Our framework wraps any black-box discovery a
lgorithm with randomized data subsampling to certify that inclusion decisions ov
er circuit components—neurons or edges of the model graph, depending on the base
algorithm—are invariant to bounded edit-distance perturbations of the concept d
ataset. Unstable components are abstained from, yielding circuits that are more
compact and more accurate. We validate across three architectures (ResNet, ViT,
GPT-2) on vision (ImageNet and four OOD datasets) and language (IOI, IOI-Hard, G
reater-Than) tasks. Certified circuits achieve up to 56% higher accuracy and up
to 80% fewer components, and remain reliable where baselines degrade. *Certified
Circuits* puts circuit discovery on formal ground by producing mechanistic expl
anations that are provably stable and better aligned with the target concept. Co
de: https://github.com/AlaaAnani/certified-circuits.

Continual Model Routing in Evolving Model Hubs
Jack Bell, Giacomo Carfi', Gerlando Gramaglia, Vincenzo Lomonaco
AI model hubs provide access to a rapidly growing collection of powerful pre-tra
ined models, enabling off-the-shelf mixture-of-experts systems with different ro
uting strategies. However, this rapid growth poses two fundamental challenges: s
caling model selection across thousands of experts and continually updating rout
ing mechanisms as new models and tasks are introduced. In this paper, we formali
se this setting as Continual Model Routing (CMR) and propose *CMRBench*, a new l
arge-scale benchmark simulating realistic hub expansion and including over 2,000
candidate models. Finally, we introduce *CARvE*, a contrastive embedding approa
ch for efficient continual model routing via domain-stratified coreset replay an
d checkpoint-based anchoring. Extensive empirical results and ablations show tha
t CARvE significantly outperforms zero-shot retrieval, fine-tuning, and adapter-
merging baselines in model, family, and domain-level accuracy.

Watermarking Graph Neural Networks via Explanations for Ownership Protection
Jane Downer, Yingdan Shi, Ziyan Liu, Ren Wang, Binghui Wang
Graph Neural Networks (GNNs) are widely deployed in industry, making their intel
lectual property valuable. However, protecting GNNs from unauthorized use remain
s a challenge. Watermarking offers a solution by embedding ownership information
into models. Existing watermarking methods have two limitations: First, they ra
rely focus on graph data or GNNs. Second, the \emph{de facto} backdoor-based met
hod relies on manipulating training data, which can introduce ownership ambiguit

y through misclassification and vulnerability to data poisoning attacks that can interrupt the backdoor mechanism. Our explanation-based watermarking inherits the strengths of backdoor-based methods (e.g., black-box verification) without data manipulation, eliminating ownership ambiguity and data dependencies. In particular, we watermark GNN explanations such that these explanations are statistically distinct from others, so ownership claims must be verified through statistical significance. We theoretically prove that, even with full knowledge of our method, locating the watermark is NP-hard. Empirically, our method demonstrates robustness to fine-tuning and pruning attacks. By addressing these challenges, our approach significantly advances GNN intellectual property protection.

Mean-Shift PCA by Knockoff Mean

Mengda Li, Zeng Li, Jianfeng Yao

Removing noise is difficult, but adding noise is easy. In this work, we show how to eliminate mean-shift noisy components from PCA by deliberately introducing knockoff mean-shift perturbation. Standard PCA is highly sensitive to shifts in the sample mean: a small fraction of samples from a shifted distribution can cause large deviations in the leading principal components. In high-dimensional regimes, existing Robust PCA approaches cannot handle the mean-shift contamination structure inherent in the mixture model. Using tools from Random Matrix Theory, we prove that the mean-shift spikes are spectrally separable from the stable eigenvalues of the original covariance. Furthermore, the original eigenspace remains asymptotically invariant to the contamination, independent of the mixture weight. Exploiting this spectral stability, we propose a simple, two-stage PCA algorithm by adding knockoff mean that identifies and removes the mean-shift component using only standard PCA operations.

Scalable Single-Cell Gene Expression Generation with Latent Diffusion Models

Giovanni Palla, Sudarshan Babu, Payam Dibaeinia, James D Pearce, Donghui Li, Aly A Khan, Theofanis Karaletsos, Jakub M. Tomczak

Computational modeling of single-cell gene expression is crucial for understanding cellular processes, but generating realistic expression profiles remains a major challenge. This difficulty arises from the count nature of gene expression data and complex latent dependencies among genes. Existing generative models often impose artificial gene orderings or rely on shallow neural network architectures. We introduce a scalable latent diffusion model for single-cell gene expression data, which we refer to as scLDM, that respects the fundamental exchangeability property of the data. Our VAE uses fixed-size latent variables leveraging a unified Multi-head Cross-Attention Block (MCAB) architecture, which serves dual roles: permutation-invariant pooling in the encoder and permutation-equivariant unpooling in the decoder. We enhance this framework by replacing the Gaussian prior with a latent diffusion model using Diffusion Transformers and linear interpolants, enabling high-quality generation with multi-conditional classifier-free guidance. We show its superior performance in a variety of experiments for both observational and perturbational single-cell data, as well as downstream tasks like cell-level classification.

Variational inference via Gaussian interacting particles in the Bures-Wasserstein geometry

Giacomo Borghi, Jose A. Carrillo

Motivated by variational inference methods, we propose a zeroth-order algorithm for solving optimization problems in the space of Gaussian probability measures. The algorithm is based on an interacting system of Gaussian particles that stochastically explore the search space and self-organize around global minima via a consensus-based optimization (CBO) mechanism.

Its construction relies on the Linearized Bures–Wasserstein (LBW) space, a novel parametrization of Gaussian measures we introduce for efficient computations. We establish well-posedness and study the convergence properties of the particle dynamics via a mean-field approximation. Numerical experiments on variational inference tasks demonstrate the algorithm’s robustness and superior performance wi

th respect to deterministic gradient-based method in presence of low-dimensional non log-concave targets.

CURE: Consistency-under-Unified Semantic Regularization for Generalized Category Discovery
Yuwei Bian, Shidong Wang, Haofeng Zhang
Generalized Category Discovery (GCD) aims to learn semantically structured representations for discovering novel categories in unlabeled data using supervision from known classes. Most existing methods rely on self-supervised contrastive learning (CL) with consistency and uniformity objectives. We identify an inherent optimization conflict between these objectives: while uniformity enforces global feature dispersion, it can hinder the formation of class-discriminative and semantically coherent structures.
To address this issue, we propose a two-stage framework that decouples representation learning from self-contrastive regularization. The first stage learns category-anchored representations aligned with known class prototypes, while the second stage extends the representation space to novel categories via a consistency objective enhanced with unified semantic regularization. We further introduce a Semantic Exploration Energy mechanism to capture shared semantics across categories and mitigate information loss caused by prototype orthogonalization. The resulting framework, termed *Consistency-under-Unified Semantic Regularization*(**CURE**), achieves state-of-the-art performance on multiple benchmarks and substantially reduces the performance gap between known and novel categories.
****
ORLoopBench: Solver-in-the-Loop Benchmarks for Self-Correction and Behavioral Rationality in Operations Research
Ruicheng Ao, David Simchi-Levi, Xinshang Wang
Operations Research practitioners debug infeasible models through an iterative process: inspecting Irreducible Infeasible Subsystems (\textbf{IIS}), identifying constraint conflicts, and repairing formulations until feasibility is restored. Existing LLM benchmarks mostly treat OR as one-shot translation from problem descriptions to solver code, omitting this diagnostic loop. We formalize infeasible-model repair as a solver-in-the-loop Markov Decision Process in which each action triggers solver re-execution and \textbf{IIS} recomputation, yielding deterministic, verifiable feedback. We introduce \textbf{ORLoopBench}, a benchmark suite with two components: \textbf{ORDebug} releases 5,362 LP/MILP repair instances, while \textbf{ORBias} evaluates closed-form operational decision rationality across inventory settings. Solver-verified RLVR training enables an 8B model to surpass frontier APIs on LP repair (95.3\% vs 92.4\% RR@5), improves diagnostic behavior, and transfers to MILP repair. The same evaluation exposes semantic drift in whole-model code regeneration: feasible regenerated MILPs can solve the wrong problem. Process-level evaluation with solver oracles enables targeted training for reliable OR self-correction.
****
Improving Classifier-Free Guidance of Flow Matching via Manifold Projection
Jian-Feng Cai, Haixia Liu, Zhengyi Su, Chao Wang
Classifier-free guidance (CFG) is a widely used technique for controllable generation in diffusion and flow-based models. Despite its empirical success, CFG relies on a heuristic linear extrapolation that is often sensitive to the guidance scale. In this work, we provide a principled interpretation of CFG through the lens of optimization. We demonstrate that the velocity field in flow matching corresponds to the gradient of a sequence of smoothed distance functions, which guides latent variables toward the scaled target image set. This perspective reveals that the standard CFG formulation is an approximation of this gradient, where the prediction gap, the discrepancy between conditional and unconditional outputs, governs guidance sensitivity. Leveraging this insight, we reformulate the CFG sampling as a homotopy optimization with a manifold constraint. This formulation necessitates a manifold projection step, which we implement via an incremental gradient descent scheme during sampling. To improve computational efficiency and stability, we further enhance this iterative process with Anderson Acceleratio

n without requiring additional model evaluations. Our proposed methods are train
ing-free and consistently refine generation fidelity, prompt alignment, and robu
stness to the guidance scale. We validate their effectiveness across diverse ben
chmarks, demonstrating significant improvements on large-scale models such as D
iT-XL-2-256, Flux, and Stable Diffusion 3.5. Code is available at https://github
.com/LeonSuZhengYi/CFG-MP.

PAWS: Preference Learning with Advantage-Weighted Segments
Aleksandar Taranovic, Onur Celik, Niklas Freymuth, Ge Li, Serge Thilges, Huy Le,
 Tai Hoang, Rania Rayyes, Gerhard Neumann
Preference-based reinforcement learning (PbRL) learns policies from human trajec
tory-level comparisons, avoiding explicit reward design and expert demonstration
s. Existing methods typically train utility functions on trajectory or segment-l
evel preferences while relying on per-step utility estimates during policy optim
ization. This training and inference mismatch induces a distribution shift that
severely degrades temporal credit assignment and limits policy learning.
We analyze this issue and propose PAWS, a segment-based preference learning meth
od that performs policy updates directly using segment-level advantage functions
. By aligning utility training with policy optimization, PAWS preserves trajecto
ry-level preference information and avoids unreliable per-step learning signals.
 Experiments on simulated robotic manipulation and locomotion tasks demonstrate
that PAWS consistently outperforms existing PbRL approaches, highlighting the im
portance of distribution-consistent preference learning.

Smoothie: Smoothing Diffusion on Token Embeddings for Text Generation
Alexander Shabalin, Viacheslav Meshchaninov, Dmitry Vetrov
Diffusion models have achieved state-of-the-art performance in generating images
, audio, and video, but their adaptation to text remains challenging due to its
discrete nature. Prior approaches either apply Gaussian diffusion in continuous
latent spaces, which inherits semantic structure but struggles with token decodi
ng, or operate in categorical simplex space, which respect discreteness but disr
egard semantic relation between tokens. In this paper, we propose Smoothing Diff
usion on Token Embeddings (Smoothie), a novel diffusion method that combines the
 strengths of both approaches by progressively smoothing token embeddings based
on semantic similarity. This technique enables gradual information removal while
 maintaining a natural decoding process. Experimental results on several sequenc
e-to-sequence and unconditional generation tasks demonstrate that Smoothie outpe
rforms existing diffusion-based models in generation quality. Furthermore, ablat
ion studies show that our proposed diffusion space yields better performance tha
n both the standard embedding space and the categorical simplex.

Synthesizing Multimodal Geometry Datasets from Scratch and Enabling Visual Align
ment via Plotting Code
Haobo Lin, Tianyi Bai, Chen Chen, Jiajun Zhang, Bohan Zeng, Wentao Zhang, Binhan
g Yuan
Multimodal geometry reasoning requires models to jointly understand visual diagr
ams and perform
structured symbolic inference, yet current vision--language models struggle with
 complex geometric
constructions due to limited training data and weak visual--symbolic alignment.
We propose a pipeline for synthesizing complex multimodal geometry problems from
 scratch and construct
a dataset named \textbf{GeoCode}, which decouples problem generation into symbol
ic seed construction,
grounded instantiation with verification, and code-based diagram rendering, ensu
ring consistency across
structure, text, reasoning, and images.
Leveraging the plotting code provided in GeoCode, we further introduce code pred
iction as an explicit
alignment objective, transforming visual understanding into a supervised structu

red prediction task.
GeoCode exhibits substantially higher structural complexity and reasoning difficulty than existing benchmarks,
while maintaining mathematical correctness through multi-stage validation.
Extensive experiments show that models trained on GeoCode achieve consistent improvements on multiple geometry
benchmarks, demonstrating both the effectiveness of the dataset and the proposed alignment strategy.

Understanding Private Learning From Feature Perspective
Meng Ding, Mingxi Lei, Shaopeng Fu, Shaowei Wang, Di Wang, Jinhui Xu
Differentially private Stochastic Gradient Descent (DP-SGD) has become integral to privacy-preserving machine learning, ensuring robust privacy guarantees in sensitive domains. Despite notable empirical advances leveraging features from non-private, pre-trained models to enhance DP-SGD training, a theoretical understanding of feature dynamics in private learning remains underexplored. This paper presents the first theoretical framework to analyze private training through a feature learning perspective. Building on the multi-patch data structure from prior work, our analysis distinguishes between label-dependent feature signals and label-independent noise—a critical aspect overlooked by existing analyses in the DP community. Employing a two-layer CNN with polynomial ReLU activation, we theoretically characterize both feature signal learning and data noise memorization in private training via noisy gradient descent. Our findings reveal that (1) Effective private signal learning requires a higher signal-to-noise ratio (SNR) compared to non-private training, and (2) When data noise memorization occurs in non-private learning, it will also occur in private learning, leading to poor generalization despite small training loss. Our findings highlight the challenges of private learning and prove the benefit of feature enhancement to improve SNR. Experiments on synthetic and real-world datasets also validate our theoretical findings.
****

Understanding the Ability of LLMs to Handle Character-Level Perturbation
Anyuan Zhuo, Xuefei Ning, Ningyuan Li, Jingyi Zhu, Yu Wang, Pinyan Lu
This work investigates the resilience of contemporary large language models (LLMs) against frequent character-level perturbations. We examine three types of character-level perturbations including introducing numerous typos within words, shuffling the characters in each word, and inserting a large number of invisible characters into the text. Surprisingly, even under severe perturbation, such as shuffling nearly all words character-wise to produce text that is almost unreadable to humans, or inserting invisible characters which are several times more than the visible ones as noise, many LLMs still maintain notable performance. We explore the underlying causes of this robustness and find that LLMs exhibit remarkable resilience to chaotic segmentation and fragmented tokenization. Furthermore, we examine the mechanisms by which LLMs remove perturbations to correctly comprehend text, including both implicit and explicit mechanisms for character-level perturbation. We hope that our findings on the low-level robustness of LLMs will unveil their inherent architectural strengths, reveal the potential risks of their misuse, and inform the reliable deployment of LLMs across diverse application scenarios.
****

MER-DG: Modality-Entropy Regularization for Multimodal Domain Generalization
Yavuz Yarici, Ghassan AlRegib
Deploying multimodal models in real-world scenarios requires generalization to new environments where recording conditions differ from training, a challenge known as multimodal domain generalization (MMDG). Standard architectures employ separate encoders for each modality and a fusion module, training the system end-to-end by optimizing on the fused features. In this paper, we identify that such joint optimization causes encoders to exploit cross-modal co-occurrences, statistical relationships between modalities that arise from source-specific recording conditions, rather than learning domain-invariant features. We term this failure

mode Fusion Overfitting. To address this, we propose Modality-Entropy Regulariz
ation for Domain Generalization (MER-DG), which maximizes the entropy of each en
coder's feature distribution to preserve feature diversity. MER-DG is architectu
re-agnostic and integrates into existing multimodal frameworks as an additive lo
ss term. Extensive experiments on EPIC-Kitchens and HAC benchmarks demonstrate a
verage improvements of ${\sim}5\%$ over standard fusion and ${\sim}2\%$ over sta
te-of-the-art methods.
****
TopoDistill: Distilling Global System Topology for Causal Discovery in Multivari
ate Time Series
Zehao Liu, Pengfei Jiao, Yuhan Wu, Jianqi Yang, Yuyu Yin
Although causal discovery from multivariate time series is widely used, it remai
ns challenging under noise. Convergent cross mapping (CCM) infers causality by r
econstructing shadow manifolds via time-delay embedding (TDE) and evaluating cro
ss-map skill between manifolds. Despite Takens’ theorem guarantees in ideal sett
ings, TDE effectively attempts to recover system state from a single noisy view,
 often yielding geometrically degraded manifolds and unreliable distance-based n
eighborhoods, which in turn weakens causal identification. We propose TopoDistil
l, a topology-informed knowledge distillation framework that improves univariate
 shadow-manifold reconstruction by aligning local neighborhood structure to a mu
ltivariate system representation. A global embedder trained on multivariate obse
rvations captures a global attractor representation, while a delay embedder is d
istilled to produce embeddings whose neighborhood distributions match the global
 topology. This cross-view alignment yields smoother and more reliable neighborh
oods, improving cross mapping under noise while maintaining specificity against
spurious correlations. Theoretical analysis and experimental results demonstrate
 that our method enables effective causal discovery.

Explicit representation of germline and non-germline residues improves antibody
language modeling
Jeonghyeon Kim, Nathaniel Blalock, Ameya Kulkarni, Kensuke Nakamura, Philip Rome
ro
Antibodies originate from germline templates and are diversified by somatic hype
rmutation, producing sequences in which conserved germline residues scaffold str
ucture while rare non-germline (NGL) substitutions refine antigen binding. Curre
nt antibody language models (ALMs) treat all residues equivalently and inherit a
 germline bias that systematically down-weights functionally critical NGL mutati
ons as statistical noise. We introduce PRISM, a germline-aware ALM that explicit
ly represents germline and non-germline residues as distinct token types over a
factorized 53-token vocabulary. PRISM achieves state-of-the-art pseudo-perplexit
y in hypervariable CDRs and is uniquely positively correlated with experimental
binding affinity across three deep mutational scanning landscapes on which all c
ompared ALMs anti-correlate. The dual-vocabulary further enables property-specif
ic controllable generation previously unattainable with entangled ALMs. NGL-dire
cted sampling improves physics-based binding scores while GL-directed sampling p
reserves stability and solubility. These results establish disentangled germline
/non-germline representation as a substantive advance in antibody language model
ing.
****
TeamTR: Trust-Region Fine-Tuning for Multi-Agent LLM Coordination
Yi Xie, Siao Liu, Falong FAN, Yuanqi Yao, Siyang Cao, Yue Zhao, Bo Liu
Multi-agent LLM systems can improve reasoning and tool use, yet recent evidence
shows their gains are often unstable and sensitive to interaction design.
A promising direction is to train collaboration, but team post-training introduc
es a moving-target effect: when agents interact through a shared context, updati
ng one agent shifts the context distribution faced by the others, which can regr
ess coordination under naive sequential updates.
We propose TeamTR, a trust-region framework for fine-tuning heterogeneous LLM te
ams that explicitly controls this occupancy shift.
TeamTR evaluates each agent update on rollouts from the intermediate team induce

d by partially applied updates, and enforces per-agent trust regions via a token-decomposed reverse KL that is directly monitorable from those rollouts.
This yields population-level per-update and per-stage improvement lower bounds whose functional form applies to any realized update order, and motivates a practical certificate proxy computed from logged surrogates and KL terms.
We instantiate TeamTR for router-based text handoff with sequence-level returns and bounded group-normalized advantages, and show empirically that it mitigates coordination regressions, improves training stability across heterogeneous teams, and supports modular component replacement via a trust-region alignment step.

Saliency-Aware Model Merging
Jungin Park, Jiyoung Lee, Kwanghoon Sohn
Model merging aims to consolidate multiple task-specific models fine-tuned on different datasets into a unified architecture that performs cross-domain proficiency.

Current data-free model merging methods often struggle to scale as they rely on simple parameter-level heuristics that ignore inter-layer dependencies and non-uniform distribution of expertise.

This work proposes SA-Merging, which is built upon connectivity-based saliency formulations from structural pruning (e.g., SynFlow) and extends them to the data-free model merging setting.

We define a saliency score over task vectors relative to a shared base model, and further introduce merge-aware modulation that incorporates agreement across experts to mitigate task interference.

Based on this formulation, an iterative saliency-aware merging procedure progressively removes non-informative updates while preserving end-to-end connectivity.

Furthermore, we extend SA-Merging to introduce rank-wise saliency decomposition for LoRAs without compromising their structural integrity.

Extensive experiments on vision and language tasks demonstrate the effectiveness of our saliency-based approach, further reducing the gap between data-free and test-time adaptation methods.

DITING: A Weak Degradation Listener for Battery Lifetime Early Prediction
Hao Miao, Ni Zhang, Zefei Ning, Li Wang
Battery lifetime early prediction is crucial for safety assessment and decision planning, yet early-stage degradation signals are extremely weak and difficult to distinguish from stochastic noise. Existing methods primarily rely on denoising or signal decomposition, which may lose critical degradation cues. In nature, most organisms exhibit the binaural effect, exploiting discrepancies between left and right auditory inputs to enhance perceptual reliability. Inspired by this, we propose DITING, a weak degradation listener for battery lifetime early prediction. We first employ optimal-transport-based selective matching to extract a robust health template from initial cycles, and further design a tri-coupled degradation manifestation mechanism to distinguish degradation signals from noise. By exploiting the randomness of noise, matched responses under symmetric coupling suppress stochastic fluctuations, while degradation-driven cumulative deviations propagate through the coupling process to form stable bilateral discrepancies, thereby amplifying weak early-stage cues for lifetime prediction. Experiments on various datasets demonstrate that DITING achieves state-of-the-art performance and provides more reliable early support for full-lifecycle battery management.

Characterizing, Evaluating, and Optimizing Complex Reasoning
Haoran Zhang, Yafu Li, Zhi Wang, Zhilin Wang, Shunkai Zhang, Xiaoye Qu, Yu Cheng
Large Reasoning Models (LRMs) increasingly rely on reasoning traces with complex internal structures. However, existing work lacks a unified answer to three fundamental questions:
(1) what defines high-quality reasoning,
(2) how to reliably evaluate long, implicitly structured reasoning traces, and
(3) how to use such evaluation signals for reasoning optimization.

To address these challenges, we provide a unified perspective. (1) We introduce the ME^2 principle to characterize reasoning quality along macro- and micro-level concerning efficiency and effectiveness. (2) Built on this principle, we model reasoning traces as directed acyclic graphs (DAGs) and develop a DAG-based pairwise evaluation method, capturing complex reasoning structures. (3) Based on this method, we construct the TRM-Preference dataset and train a Thinking Reward Model (TRM) to evaluate reasoning quality at scale.
Experiments show that thinking rewards serve as an effective optimization signal. At test time, selecting better reasoning leads to better outcomes (up to 19.3\% gain), and during RL training, thinking rewards enhance reasoning and performance (up to 3.9\% gain) across diverse tasks. Code and data are available at https://github.com/Simplified-Reasoning/TRM.

Breaking the Exploration Bottleneck: Rubric-Scaffolded Reinforcement Learning for Open-Ended LLM Reasoning
Yang Zhou, Sunzhu Li, Shunyu Liu, Wenkai Fang, Kongcheng Zhang, Jiale Zhao, Jingwen Yang, Yihe Zhou, Jianwei Lv, Tongya Zheng, Hengtong Lu, Chen Wei, Xie Yan, Mingli Song
Recent advances in Large Language Models (LLMs) have underscored the potential of Reinforcement Learning (RL) to facilitate the emergence of reasoning capabilities. Despite the encouraging results, a fundamental dilemma persists as RL improvement relies on learning from high-quality samples, yet the exploration for such samples remains bounded by the inherent limitations of LLMs. This, in effect, creates an undesirable cycle in which what cannot be explored cannot be learned. In this work, we propose Rubric-Scaffolded Reinforcement Learning (RuscaRL), a novel instructional scaffolding framework designed to break the exploration bottleneck for open-ended reasoning. Specifically, RuscaRL introduces checklist-style rubrics as (1) explicit scaffolding for exploration during rollout generation, where different rubrics are provided as external guidance within task instructions to steer diverse high-quality responses. This guidance is gradually decayed over time, encouraging the model to internalize the underlying reasoning patterns; (2) verifiable rewards for exploitation during model training, where we can obtain robust LLM-as-a-Judge scores using rubrics as references, enabling effective RL on open-ended reasoning tasks. Extensive experiments demonstrate the superiority of the proposed RuscaRL across various benchmarks, effectively expanding reasoning boundaries under the Best-of-N evaluation.

WIND: Weather Inverse Diffusion for Zero-Shot Atmospheric Modeling
Michael Aich, Andreas Fürst, Florian Sestak, Carlos Ruiz-Gonzalez, Niklas Boers, Johannes Brandstetter
Deep learning has revolutionized weather forecasting, but many challenges remain, including climate modeling. Moreover, the current landscape remains fragmented: highly specialized models are typically trained individually for distinct tasks. To unify this landscape, we introduce WIND, a single pre-trained foundation model capable of replacing specialized baselines across a vast array of tasks. Crucially, in contrast to previous atmospheric foundation models, we achieve this without any task-specific fine-tuning. To learn a robust, task-agnostic prior of the atmosphere, we pre-train WIND with a self-supervised video reconstruction objective, utilizing an unconditional video diffusion model to iteratively reconstruct atmospheric dynamics from a noisy state. At inference, we frame diverse domain-specific problems strictly as inverse problems and solve them via posterior sampling. This unified approach allows us to tackle highly relevant weather and climate problems, including probabilistic forecasting, spatial and temporal downscaling, reconstruction of spatial fields from sparse observations and enforcing global dry air mass conservation. We further demonstrate how WIND can be applied to explore extreme weather events under prescribed out-of-distribution thermodynamic perturbations. By combining generative video modeling with inverse problem solving, WIND offers a computationally efficient alternative for AI-based atmospheric modeling.

DEER: A Benchmark for Evaluating Deep Research Agents on Expert Report Generation

Janghoon Han, Heegyu Kim, Changho Lee, Dahm Lee, Min Hyung Park, Hosung Song, Stanley Jungkyu Choi, Moontae Lee, Honglak Lee

Recent advances in large language models have enabled deep research systems that generate expert-level reports through multi-step reasoning and evidence-based synthesis. However, evaluating such reports remains challenging: report quality is multifaceted, making it difficult to determine what to assess and which criteria to use; LLM-based judges may miss errors that require domain expertise to identify; and because deep research relies on retrieved evidence, report-wide claim verification is also necessary. To address these issues, we propose DEER, a benchmark for evaluating expert-level deep research reports. DEER systematizes evaluation criteria with an expert-developed taxonomy (7 dimensions, 25 subdimensions) operationalized as 101 fine-grained rubric items. We also provide task-specific Expert Evaluation Guidance to support LLM-based judging. In addition to rubric-based assessment, we propose a claim verification architecture that verifies both cited and uncited claims and quantifies evidence quality.

Experiments show that current systems produce structurally plausible, evidence-citing reports, but still struggle to fully satisfy expert-level user requests and achieve logical completeness. Beyond performance comparisons, DEER makes system strengths and limitations interpretable and provides diagnostic signals for improvement.

****

QuITE: Query-Based Irregular Time Series Embedding

Junghoon Lim

Irregular Multivariate Time Series (IMTS) are common in practice, yet their irregular sampling complicates effective modeling. Existing approaches typically either (i) design specialized architectures that limit the reuse of proven Multivariate Time Series (MTS) models, or (ii)

map IMTS onto regular temporal grids through interpolation, which may distort temporal dynamics by introducing artificial values. To address these limitations, we propose a new input-embedding-based approach. We identify that the key bottleneck lies not in the backbone architecture, but in conventional embedding layers that assume uniform sampling. In this work, we introduce QuITE (Query-Based Irregular Time Series Embedding), a simple yet effective plug-and-play embedding module for IMTS. QuITE employs learnable query tokens to aggregate irregular observations through a single self-attention layer, directly producing backbone-compatible latent representations without artificial value generation or architectural modification. Extensive experiments on real-world benchmarks show that QuITE consistently improves MTS models, yielding average relative gains of up to 54.7% in forecasting and 15.8% in classification across diverse datasets and backbone architectures.

A Refined Generalization Analysis for Extreme Multi-class Supervised Contrastive Representation Learning

Nong Minh Hieu, Antoine Ledent

Contrastive Representation Learning (CRL) has achieved strong empirical success in multiple machine learning disciplines, yet its theoretical sample complexity remains poorly understood. Existing analyses usually assume that input tuples are identically and independently distributed, an assumption violated in most practical settings where contrastive tuples are constructed from a finite pool of labeled data, inducing dependencies among tuples. While one recent work analyzed this learning setting using U-Statistics to estimate the population risk, the techniques used therein require the risk of each class to concentrate uniformly, making excess risk bounds scale in the order of $\rho_{\min}^{-{1}/{2}}$ where $\rho_{\min}$ denotes the probability of the rarest class. Such a dependency can be overly pessimistic in the extreme multiclass settings where there are many tail classes which contribute minimally to the overall population risk. Our contributions are two-fold. Firstly, we improve upon the previous work and prove a bound with a sample complexity of the same order as the number of classes R, regard

less of the distribution over classes. Furthermore, we formulate a different est
imator that captures the concentration of the risk \textit{across classes}, enab
ling sharper bounds in extreme multi-class learning scenarios, especially where
class distributions are long-tailed. Under mild assumptions on the class distrib
utions, the resulting sample complexity is $\mathcal{{O}}(k)$ where k is the n
umber of samples per tuple.

RELO: Reinforcement Learning to Localize for Visual Object Tracking
Xin Chen, Chuanyu Sun, Jiao Xu, Houwen Peng, Dong Wang, Huchuan Lu, Kede Ma
Conventional visual object trackers localize targets using handcrafted spatial p
riors, often in the form of heatmaps. Such priors provide only surrogate supervi
sion and are poorly aligned with tracking optimization and evaluation metrics, s
uch as intersection over union (IoU) and area under the success curve (AUC). Her
e, we introduce RELO, a REinforcement-learning-to-LOcalize method for visual obj
ect tracking that formulates target localization as a Markov decision process. S
pecifically, RELO replaces handcrafted spatial priors with a localization policy
 learned over spatial positions via reinforcement learning, with rewards combini
ng frame-level IoU and sequence-level AUC. We additionally introduce layer-align
ed temporal token propagation to improve semantic consistency across frames, wit
h negligible computational overhead. Across multiple benchmarks, RELO achieves s
uperior results, attaining 57.5\% AUC on LaSOT$_\mathrm{ext}$ without template
 updates. This confirms that reward-driven localization provides an effective al
ternative to prior-driven localization for visual object tracking.

Gradient Flow Dynamics and Implicit Bias of Diagonal Linear Networks under Infin
itesimal Initialization
Jiajie Zhao, Jianxing Wang, Junjie Yang, Zhiwei Bai, Yaoyu Zhang
We study the gradient flow dynamics of diagonal linear networks for regression t
asks under infinitesimal initialization. Extending Theorem 1 from Pesme & Flamma
rion (2023), we generalize the analysis to both deep diagonal linear networks an
d a broader class of two-layer diagonal linear networks (as defined in Definitio
n 4.1). Specifically, we demonstrate that the training trajectories of these mod
els can be equivalently characterized by the proposed Algorithm 1. We further pr
ove that this algorithm converges to the solution of a modified $\mathcal{l}_1$
norm minimization problem. As a result, we establish that the implicit bias of b
oth network architectures corresponds to a modified $\mathcal{l}_1$ norm in the
regime of infinitesimal initialization. Additionally, we provide insights into t
he underlying mechanisms governing these dynamics by identifying the Structural
Invariant Manifold (SIM) (Zhao et al., 2026) as the key geometric structure that
 shapes the learning process.

Context-Aware Reasoner: Enhancing Contextual Reasoning in Multimodal Large Langu
age Models
Zhe Zheng, Wenqi Zhang, Xiaohe Zhou, Guiyang Hou, Xinyu Mei, Tianyang Mao, Anni
PIAO, Shengpei Jiang, Yongliang Shen, Yueting Zhuang, Weiming Lu
Multimodal large language models (MLLMs) have demonstrated remarkable reasoning
capabilities over internalized knowledge. However, current research overlooks co
ntextual reasoning, the ability to reason based on the relevant information pres
ent in the context. To investigate this issue, we construct the Visual Contextua
l Reasoning Benchmark (ContextReasonV-Bench), and our analysis reveals two predo
minant failure modes: *context neglect*, where models rely on pre-trained knowle
dge instead of contextual information, and *superficial pattern matching*, where
 models exploit shallow correlations rather than genuine patterns. To address th
ese limitations, we propose a two-stage approach that progressively establishes
and reinforces contextual pattern acquisition. The first stage establishes an "a
nalyze-then-solve" reasoning paradigm through supervised fine-tuning (SFT). We t
hen employ a context-aware reinforcement learning (RL) framework that integrates
 context-aware reward modeling with hierarchical advantage estimation to encoura
ge the model to identify genuine contextual patterns. This approach yields Conte
xt-Aware Reasoner (CAR), a model that achieves 38.14\% accuracy on ContextReason

V-Bench, a 22.09\% improvement over the base model, and generalizes effectively to unseen tasks.
****
Spatially-Regularized Entropy for Discriminative Token Merging in Fine-Grained Re-Identification
Shangze Li, Yifan Xu, Jingmiao Liang, Yongfei Zhang, Yuzhuo Ma, Yingbo Qu
While Vision Transformers (ViTs) offer strong global modeling, their quadratic computational cost limits utility in latency-sensitive applications like person re-identification (ReID). Existing compression strategies, such as token pruning or generic merging, typically rely on coarse-grained criteria tailored for image classification. In fine-grained retrieval, these approaches often discard or smooth out subtle but discriminative local details. To resolve this, we propose SRE-Merge, a training-free framework designed for discriminative token compression. SRE-Merge injects spatial priors into the merging process through three mechanisms: (i) Spatial-Entropy Saliency Assessment (SES-Assess), which quantifies token importance as Spatial-Entropic Mass (SE-Mass) by coupling spatial structure with local attention entropy; (ii) Hybrid Context-Affinity Matching (HCA-Match), which guides precise pair selection by combining feature similarity with mass-derived context; and (iii) Energy-Preserving Weighted Fusion (EPW-Fuse), which incorporates SE-Mass weighting to counteract feature variance reduction. Extensive experiments on standard benchmarks show that SRE-Merge reduces GFLOPs of the base ViT model by about 24\% while retaining competitive retrieval accuracy, establishing a superior accuracy-efficiency trade-off.
****
Absorbing Quantization Error by Deformable Noise Scheduler for Diffusion Models
Mingrui Yang, Wei Huang, Hao Nan SHENG, Donglin Yang, Jichang Yang, Xin Yu, Huining Yu, Yuzhong Jiao, Zhongrui Wang, Xiaojuan Qi
Diffusion models deliver state-of-the-art image quality but are expensive to deploy. Post-training quantization (PTQ) can shrink models and speed up inference, yet residual quantization errors distort the diffusion distribution (the timestep-wise marginal over $\boldsymbol{x}_t$), degrading sample quality. We propose a distribution-preserving framework that absorbs quantization error into the generative process without changing architecture or adding steps.
Deformable Noise Scheduler (DNS) reinterprets quantization as a principled timestep shift, mapping the quantized prediction distribution $\boldsymbol{x}_t$ back onto the original diffusion distribution so that the target marginal is preserved.
Unlike trajectory-preserving or noise-injection methods limited to stochastic samplers, our approach preserves the distribution under both stochastic and deterministic samplers and extends to flow-matching with Gaussian conditional paths. It is plug-and-play and complements existing PTQ schemes.
Empirically, our method consistently enhances generation quality across diverse backbones and existing PTQ baselines. Notably, when further quantizing the FP16 LoRA branch of SVDQuant to enable fully integer inference, our approach effectively mitigates the performance drop, reducing FID from 27.16 to 26.22. Code is available at https://github.com/ZephyrYoung-eYuan/DNS_AQE
****
AnomSeer: Reinforcing Multimodal LLMs to Reason for Time-Series Anomaly Detection
Junru Zhang, Lang Feng, Haoran Shi, Xu Guo, Han Yu, Yabo Dong, Duanqing Xu
Time-series anomaly detection (TSAD) with multimodal large language models (MLLMs) is an emerging area, yet a persistent challenge remains: MLLMs rely on coarse time-series heuristics but struggle with multi-dimensional, detailed reasoning, which is vital for understanding complex time-series data. We present AnomSeer to address this by reinforcing the model to ground its reasoning in precise, structural details of time series, unifying anomaly classification, localization, and explanation. At its core, an expert chain-of-thought trace is generated to provide verifiable, fine-grained reasoning from classical analyses (e.g., statistical measures, frequency transforms). Building on this, we propose a novel time-series grounded policy optimization (TimerPO) that incorporates two additional c

omponents beyond standard reinforcement learning: a time-series grounded advanta ge based on optimal transport and an orthogonal projection to ensure this auxili ary granular signal does not interfere with the primary detection objective. Acr oss diverse anomaly scenarios, AnomSeer, with Qwen2.5-VL-3B/7B-Instruct, outperf orms larger commercial baselines in classification and localization accuracy, p articularly on point- and frequency-driven exceptions. Moreover, it produces pla usible reasoning traces that support its conclusions.

Diffusion Controller: Framework, Algorithms and Parameterization
Tong Yang, Moonkyung Ryu, Chih-Wei Hsu, Guy Tennenholtz, Yuejie Chi, Craig Bouti lier, Bo Dai
Controllable diffusion generation often relies on various heuristics that are se emingly disconnected without a unified understanding. We bridge this gap with Di ffusion Controller (DiffCon), a unified control-theoretic view that casts revers e diffusion sampling as state-only stochastic control within (generalized) linea rly-solvable Markov Decision Processes (LS-MDPs). Under this framework, control acts by reweighting the pretrained reverse-time transition kernels, balancing te rminal objectives against an f-divergence cost. From the resulting optimality conditions, we derive practical reinforcement learning methods for diffusion fin e-tuning: (i) f-divergence-regularized policy-gradient updates, including a PP O-style rule, and (ii) a regularizer-determined reward-weighted regression objec tive with a minimizer-preservation guarantee under the Kullback–Leibler (KL) div ergence. The LS-MDP framework further implies a principled model form: the optim al score decomposes into a fixed pretrained baseline plus a lightweight control correction, motivating a side-network parameterization conditioned on exposed in termediate denoising outputs, enabling effective *gray-box adaptation* with a fr ozen backbone. Experiments on Stable Diffusion v1.4 across supervised and reward -driven finetuning show consistent gains in preference-alignment win rates and i mproved quality–efficiency trade-offs versus gray-box baselines and even the par ameter-efficient white-box adapter LoRA.

Off-Policy Evaluation with Strategic Agents via Local Disclosure
Kiet Q. H. Vo, Abbavaram Gowtham Reddy, Julian Rodemann, Siu Lun Chau, Krikamol Muandet
We study off-policy evaluation (OPE) under strategic behavior where decision sub jects (or agents) respond to a decision maker's policy by strategically modifyin g their covariates. Such behavior induces a policy-dependent covariate shift, br eaking the standard assumption in existing methods that covariates are exogenous to the policy. Related work addresses this challenge by imposing strong assumpt ions such as repeated interactions or full knowledge of agents’ response behavio r, substantially limiting its applicability to OPE. In contrast, we consider a o ne-shot OPE setting where the decision maker has only partial knowledge of the a gents' response behavior. Our key insight is that disclosing local information t hrough post-hoc explanations reveals agents’ pre-strategic covariates prior to a daptation, mitigating the information loss induced by strategic behavior. Levera ging this structure, we estimate a statistical model for the agents’ responses a nd construct a doubly robust estimator for policy value. By assuming that the ag ents' cost sensitivity follows a conditional log-normal distribution, we establi sh consistency of the proposed estimator and validate our approach empirically. More broadly, our results highlight how interaction design can mitigate informat ion asymmetry by revealing otherwise hidden structure in agents' strategic respo nses.

Do Activation Verbalization Methods Convey Privileged Information?
Millicent Li, Alberto Mario Ceballos Arroyo, Giordano Rogers, Naomi Saphra, Byro n C Wallace
Recent interpretability methods have proposed to translate LLM internal represen tations into natural language descriptions using a second *verbalizer* LLM. This is intended to illuminate how the target model represents and operates on input s. But do such *activation verbalization* approaches actually provide *privilege

d* knowledge about the internal workings of the target model, or do they merely convey information about the inputs provided to it? We critically evaluate popular verbalization methods and datasets used in prior work and find that one can perform well on such benchmarks without access to target model internals, suggesting that these datasets are not ideal for evaluating verbalization methods. We then run controlled experiments which reveal that verbalizations often reflect the parametric knowledge of the verbalizer LLM that generated them, rather than the knowledge of the target LLM whose activations are decoded.
Taken together, our results indicate a need for targeted benchmarks and experimental controls to rigorously assess whether verbalization methods provide meaningful insights into the operations of LLMs.
****

Multimodal Fact-Level Attribution for Verifiable Reasoning
David Wan, Han Wang, Ziyang Wang, Elias Stengel-Eskin, Hyunji Lee, Mohit Bansal
Multimodal large language models (MLLMs) are increasingly used for real-world tasks involving multi-step reasoning and long-form generation, where reliability requires grounding model outputs in heterogeneous input sources and verifying individual factual claims.
However, existing multimodal grounding benchmarks and evaluation methods focus on simplified, observation-based scenarios or limited modalities and fail to assess attribution in complex multimodal reasoning.
We introduce MuRGAt (Multimodal Reasoning with Grounded Attribution), a benchmark for evaluating fact-level multimodal attribution in settings that require reasoning beyond direct observation.
Given inputs spanning video, audio, and other modalities, MuRGAt requires models to generate answers with explicit reasoning and precise citations, where each citation specifies both modality and temporal segments. To enable reliable assessment, we introduce an automatic evaluation framework that strongly correlates with human judgments. Benchmarking with human and automated scores reveals that even strong MLLMs frequently hallucinate citations despite correct reasoning.
Moreover, we observe a key trade-off: increasing reasoning depth or enforcing structured grounding often degrades accuracy, highlighting a significant gap between internal reasoning and verifiable attribution.
****

Obliviate: Efficient Unlearning in Recommender Systems
Tushar Prakash, Brijraj Singh, Niranjan Pedanekar, Narayan Chaturvedi
Machine unlearning is becoming increasingly critical in the context of data privacy regulations, particularly for recommendation systems that are directly trained on user interaction data. The goal of this work is to remove requested interaction data and their downstream influence from trained model while preserving recommendation quality, and to do so without incurring the substantial computational cost of full retraining. Existing approaches exhibit several limitations, including limited unlearning completeness and degradation in recommendation performance, while having substantial computational overhead.
In this paper, we propose Obliviate an efficient two-stage unlearning framework for recommender systems that achieves high unlearning completeness while maintaining good utility. In the first stage, we introduce a Low-Rank Unlearning Adapter (LUA), which employs a lightweight Hessian proxy to enable curvature-aware and efficient unlearning through localized low-rank adapters rather than full parameters. In the second stage, we propose Locality-Aware Calibration (LAC), a lightweight refinement stage that updates only the adapter parameters to improve the performance by enforcing unlearning via ranking-based objectives while preserving utility through knowledge distillation. Extensive empirical evaluations demonstrate that Obliviate, achieves high level of forgetting with minimal loss in recommendation quality and at significantly reduced computational cost, offering a practical and scalable solution for large-scale recommender systems.
****

Bridging the Grounding Gap in VideoQA via Typed Memory for Language-based Belief-State Reasoning
Saman Forouzandeh, Wei Peng, Xinghuo Yu, Mahdi Jalili

VideoQA models can be accurate yet often fail to align answers with the correct video segments (the \emph{grounding gap}). We introduce \textbf{LINGUA} (\textbf{L}anguage-based \textbf{IN}ference for \textbf{G}rounded Video \textbf{U}nderstanding \textbf{A}gent), a memory-based agent that performs grounded VideoQA by reasoning in an explicit \emph{linguistic belief state}. LINGUA uses five mechanisms: (1) event-driven perception (retains 8--12\% of frames while preserving 94\% of question-relevant events); (2) typed memory for episodic narratives, semantic affordances, and procedural scripts; (3) Belief-Action-Verification loops with postcondition and temporal checks; (4) meta reflection with contrastive refinement; and (5) Bayesian reliability tracking for continual learning without gradient updates. Built with Gemma3-4B (Ollama, 4-bit), LINGUA outperforms strong baselines on five VideoQA benchmarks, reaching 82.4\% on NExT-QA and 42.3\% Acc@GQA on NExT-GQA (answer + IoU$\geq$0.5 temporal localization), while running 2.6$\times$ faster than dense-frame methods. In continual learning over 100 videos, accuracy rises from 45.2\% (first 10) to 61.8\% (last 10) without catastrophic forgetting, indicating online adaptation via memory refinement.

****

Active Attacks: Red-teaming LLMs via Adaptive Environments

Taeyoung Yun, Pierre-Luc St-Charles, Jinkyoo Park, Yoshua Bengio, Minsu Kim

We address the challenge of automatically generating diverse attack prompts for large language models (LLMs) that elicit harmful behaviors (e.g., insults, sexual content) and are used for safety fine-tuning. While several prior approaches train LLMs with reinforcement learning (RL) to generate such prompts using only a toxicity classifier as a reward, existing diversity-seeking RL methods often collapse to limited modes: once high-reward prompts are found, exploration of new regions is discouraged. Inspired by the active learning paradigm that encourages adaptive exploration, we introduce \textbf{Active Attacks}, a novel RL-based red-teaming algorithm that adapts its attacks as the victim evolves. By periodically safety fine-tuning the victim LLM with collected attack prompts, we naturally induce an \emph{easy-to-hard exploration curriculum}, where the attacker progresses beyond easy modes toward increasingly difficult ones. We observe that this simple plug-and-play module, which seamlessly integrates into existing RL objectives, unexpectedly outperformed prior RL-based methods, improving cross-attack success rates against GFlowNets, the previous state-of-the-art, from 0.07\% to 31.28\% (a relative gain of more than 400×) with only a 6\% increase in computation.

Physics-Informed Pre-training on Efficient Electron-Density Images for Organic Material Property Prediction

Zhixiang Cheng, Hongxin Xiang, Mingquan Liu, Tengfei Ma, Yingzhuo Tu, Wenjie Du, Bosheng Song, Yiping Liu, xiangxiang Zeng

Precise property prediction of organic materials is pivotal for next-generation electronic and energy devices. In density functional theory (DFT), the electron density (ED) serves as the fundamental determinant of material properties. Yet, establishing it as an input modality for material property prediction has been impeded by two practical barriers: scarce large-scale ED data and the enormous computational complexity of ED representation. To bridge these gaps, we introduce VisionED, an efficient physics-informed model pre-trained on electron-density images. We curate a dataset of 2 million molecules and represent ED as multi-shot images that efficiently encode both geometric and electronic structure. VisionED is then pre-trained on 12 million multi-shot ED images via cross-scale, physics-informed pretext tasks. Empirical evaluations on photovoltaic and organic chromophore datasets show that VisionED outperforms state-of-the-art baselines by up to 27.0\%, exhibiting superior robustness under distribution shifts and data scarcity. Notably, the model generalizes to unseen device-scale applications, successfully recovering experimental trends and mixing-ratio effects in ternary blends with an average accuracy of 92.77\%. Moreover, relative to the previous ED point cloud, the ED image improves performance by 26.2\% with 2.6$\times$ fewer memory and 4.6$\times$ lower time. The code and data are available at https://github.com/ZhixiangCheng/VisionED.

****
Unifying Dataset Pruning and Distillation for Efficient Large-scale Compression
Lingao Xiao, Songhua Liu, Yang He, Xinchao Wang
Dataset pruning (DP) and dataset distillation (DD) fundamentally differ in their outputs: DP selects original image subsets, while DD generates synthetic images. Recently, DD's increasing reliance on original images suggests a convergence of the two directions. To investigate this convergence trend, we propose a unified dataset compression (DC) benchmark. This benchmark reveals an interesting trade-off for soft-label-DD: while soft labels provide valuable information, they can make the distillation process less essential, as distilled images may not always outperform random subsets. In addition, the benchmark reveals that in current stages, dataset pruning outperforms dataset distillation at small dataset sizes. Given these observations, we explore hard-label-DC as a complementary approach that emphasizes image quality while offering substantial storage efficiency. Our PCA (Prune, Combine, and Augment) is the first framework that does not rely on soft labels but instead focuses on image quality. (1) "P'' means selecting easy samples based on dataset pruning metrics, (2) "C'' indicates combining these samples effectively, and (3) "A'' is to apply constrained image augmentation during training.
****
Beyond Continuity: Simulation-free Reconstruction of Discrete Branching Dynamics from Single-cell Snapshots
Junda Ying, Yuxuan Wang, Bowen Yang, Peijie Zhou, Lei Zhang
Inferring cellular trajectories from destructive snapshots is complicated by the challenges of stochasticity and non-conservative mass dynamics such as cell proliferation and apoptosis. Existing unbalanced Optimal Transport (OT) methods treat mass as a continuous fluid, performing inference at the population level. However, this macroscopic view often fails to capture the discrete, jump-like nature of birth-death events at single-cell resolution, which is essential for understanding lineage branching and fate decisions. We present **Unbalanced Schrödinger Bridge (USB)**, a simulation-free framework for learning underlying dynamics that effectively integrates both stochastic and unbalanced effects which also models the discrete, jump-like birth–death dynamics at single-cell resolution. Theoretically, USB provides a tractable solution to the Branching Schrödinger Bridge (BSB) problem, offering a rigorous microscopic interpretation where individual cells undergo both Brownian motion and discrete birth-death jumps. Technically, the method implements an efficient solver by introducing a simulation-free training objective that effectively scales to high-dimensional omics data. Empirically, we demonstrate on both simulated and real-world datasets that USB not only achieves trajectory reconstruction performance better than or comparable to deterministic baselines but also uniquely enables realistic discrete simulation of birth-death dynamics at single-cell resolution.
****
GradPower: Powering Gradients for Faster Language Model Pre-Training
Jinbo Wang, Mingze Wang, Jiaqi Zhang, Wei Wang, Peng Pei, Xunliang Cai, Weinan E, Lei Wu
We propose **GradPower**, a lightweight gradient-transformation technique for accelerating language model pre-training. Given a gradient vector $\boldsymbol{g}=(g_{i})_{i}$, GradPower first applies the elementwise `sign-power` transformation: $ \varphi_p(\boldsymbol{g}) = \left({\rm sign}(g_i)|g_i|^p\right)_{i} $ for a fixed $p>0$, and then feeds the transformed gradient into a base optimizer. Notably, GradPower requires only a **single-line code change** and no modifications to the base optimizer’s internal logic, including the hyperparameters.
When applied to AdamW (termed **AdamWPower**), GradPower consistently achieves lower terminal loss across diverse architectures (LLaMA, Qwen2MoE), parameter scales (66M to 2B), datasets (C4, OpenWebText), and learning-rate schedules (cosine, warmup-stable-decay).
The most pronounced gains are observed when training modern mixture-of-experts models with warmup-stable-decay schedules. GradPower also integrates seamlessly

with other state-of-the-art optimizers, such as Muon, yielding further improvements. Finally, we provide theoretical analyses that reveal the underlying mechanism of GradPower and highlight the influence of gradient noise.

Adaptive Bandit Algorithms for Contextual Matching Markets
Shiyun Lin, Simon Mauras, Vianney Perchet, Nadav Merlis
We study bandit learning in matching markets, where players and arms constitute the two market sides, and the players' utilities are linear in the arm contexts. In each round, new arms arrive with observable contexts. Then, the algorithm matches them to players, aiming to minimize each player's regret against a *stable matching benchmark*. This contextual structure creates significant complexity: subtle context shifts can slightly alter one player's utility while completely reconfiguring the underlying benchmark, causing large regret spikes for others. We address this in two settings: *stochastic* contexts, drawn from a latent distribution, and *adversarial* contexts, which may be arbitrary.
For the stochastic case, we introduce a novel minimum preference gap to capture learning difficulty and provide a fully adaptive algorithm with an instance-dependent poly-logarithmic regret upper bound. We also establish matching instance-independent regret upper and lower bounds under a mild distributional assumption. For the adversarial setting, we propose a tractable regret notion that remains valid under arbitrary contexts and achieves an instance-independent sublinear regret bound via an adaptive algorithm.
****

MeshTok: Efficient Multi-Scale Tokenization for Scalable PDE Transformers
Yanshun Zhao, Xiaoyu Peng, Jiamin Jiang, Congcong Zhu, Jingrun Chen
Conventional patchified Transformers operate on uniform spatial partitions, distributing computational effort evenly across the domain irrespective of local features. This inflexible tokenization scheme is inherently limited in its ability to efficiently represent and process solutions to complex PDEs. To address this, we propose MeshTok, an adaptive mesh refinement (AMR)-inspired tokenization and sequence modeling framework. This method selectively refines spatial regions exhibiting sharp gradients, transient features, or multiscale structures, generating a heterogeneous set of multiscale tokens defined on a fixed simulation grid. These tokens are processed within a unified Transformer sequence, enabling the model to simultaneously capture coarse-grained global context and fine-grained local details without requiring specialized architectural components. Although adaptive refinement moderately increases token count, it promotes a more targeted allocation of computational resources to physically informative regions, which we view as a practical inductive bias rather than a formal optimality guarantee. Experimental evaluations across multiple PDE families and benchmark datasets demonstrate that MeshTok consistently improves the efficiency-accuracy trade-off compared to uniform-grid baselines. This suggests adaptive multiscale tokenization as a scalable and generalizable design principle for neural PDE modeling. Code is available at https://github.com/SCAILab-USTC/MeshTok.

Conditional Quantile Adjusted Conformal Prediction for Time Series
Cheng Yu, Zhoufan Zhu, Ke Zhu
Conformal prediction is challenging for time series with time-varying conditional distributions. Existing sequential conformal methods can yield volatile, non-nested prediction intervals due to noisy tail conditional quantile estimation and quantile crossing issue. To overcome these challenges, we construct prediction intervals for time series via a novel method called Conditional Quantile Adjusted Conformal Prediction (CQACP), which stabilizes sequential conformal calibration by modeling the conditional quantile curve of nonconformity score. At each time step, CQACP evaluates a base conditional quantile learner on a grid of quantile levels and fits a Cornish--Fisher approximation parameterized by conditional moments of nonconformity score with monotonicity constraints. Asymptotically, we prove the conditional validity of the prediction interval under serial dependence and show improved conditional quantile estimation accuracy. Experiments on multiple real-world datasets demonstrate that CQACP maintains accurate coverage and

produces smooth, narrow, and nested prediction intervals across different significance levels and prediction models.

SSDCN: Spatial-Spectral Dual-Clustering-based Network for Hyperspectral Image Super-resolution
Yong Yang, Xuran Zhang, Shuying Huang, Xiaozheng Wang, Weiguo Wan, Hangyuan Lu
Hyperspectral Image Single Image Super-Resolution (HSI-SISR) faces a conflict between computational efficiency and global non-local modeling.
■■Existing Transformers suffer from quadratic complexity, while window-based methods compromise global capture.
■■To address this, we propose the Spatial-Spectral Dual-Clustering-based Network (SSDCN). Our method introduces three innovations.
■■First, we design a Spatial-Spectral Dual-Cluster Block (SSDCB). Replacing expensive point-to-point attention, it uses content-driven clustering to learn low-rank structural bases, achieving global modeling with linear complexity $\mathcal{O}(KN)$.
■■Second, we propose a pyramid progressive hierarchical architecture with a Feature Reuse Reconstruction Block (FRRB).
■■It reuses the core tensor and spectral factors from coarse levels, updating only spatial factors to minimize redundancy.
■■Third, we propose a Pyramid Hierarchical Reconstruction Joint Loss to supervise intermediate levels, ensuring structural accuracy and preventing error accumulation.
■■Experiments demonstrate that SSDCN surpasses SOTA methods in metrics and visual quality with significantly fewer parameters and FLOPs, achieving an optimal efficiency-performance balance.

Domain Transfer Becomes Identifiable via a Single Alignment
Sagar Shrestha, Subash Timilsina, Hoang-Son Nguyen, Xiao Fu
Domain transfer (DT) maps source to target distributions and supports tasks such as unsupervised image-to-image translation, single-cell analysis, and cross-platform medical imaging. However, DT is fundamentally ill-posed: push-forward mappings are generally non-identifiable, as measure-preserving automorphisms (MPAs) preserve marginals while altering cross-domain correspondences, leading to content-misaligned translation. Recent work shows that MPAs can be eliminated by jointly transferring multiple corresponding source/target conditional distributions, but supervision signals labeling such conditionals are not always available in practice.
We develop an alternative route to DT identifiability. Under a structural sparsity condition on the Jacobian support pattern, we show that distribution matching together with a single paired anchor sample suffices to identify the ground-truth transfer---requiring substantially less supervision than prior approaches. To enable practical high-dimensional learning, we further propose an efficient Jacobian sparsity regularizer based on randomized masked finite differences, yielding a scalable surrogate without explicit Jacobian evaluation. Empirical results on synthetic and real-world DT tasks validate the theory.

Robust-U1: Can MLLMs Self-Recover Corrupted Visual Content for Robust Understanding?
Jiaqi Tang, Jianmin Chen, Youyang Zhai, Wei Wei, Runtao Liu, Mengjie Zhao, Xiangyu Wu, Qingfa Xiao, Qifeng Chen
Multimodal Large Language Models (MLLMs) have demonstrated remarkable success in visual understanding, yet their performance degrades significantly under real-world visual corruptions. While existing robustness enhancement approaches exist, they are limited: black-box feature alignment lacks interpretability, and white-box text-based reasoning cannot restore lost pixel-level details. This work investigates a fundamental research question: Can MLLMs recover corrupted visual content by themselves? To address this, we propose Robust-U1, a novel framework that equips MLLMs with explicit visual self-recovery capability for robust understanding. The approach comprises three core stages: supervised fine-tuning for in

itial reconstruction, reinforcement learning with dual rewards (pixel-level SSIM and semantic-level CLIP similarity) for aligning high visual quality, and multimodal reasoning that jointly considers both the corrupted input and the recovered image. Extensive experiments demonstrate that Robust-U1 achieves state-of-the-art robustness on the real-world corruption benchmark and maintains superior performance under adversarial corruptions on general VQA benchmarks. Analysis confirms that high-quality visual recovery directly enhances reasoning performance, establishing self-recovery as a critical mechanism for robust visual understanding. The source code is available at https://github.com/jqtangust/Robust-U1.

Scheduling LLM Inference with Uncertainty-Aware Output Length Predictions
Haoyu Zheng, Yongqiang Zhang, Fangcheng Fu, Xiaokai Zhou, Hao Luo, Hongchao Zhu, Yuanyuan Zhu, Hao Wang, Xiao Yan, Jiawei Jiang
To schedule LLM inference, the \textit{shortest job first} (SJF) principle is favorable by prioritizing requests with short output lengths to avoid head-of-line (HOL) blocking. Existing methods usually predict a single output length for each request to facilitate scheduling. We argue that such a \textit{point estimate} does not match the \textit{stochastic} decoding process of LLM inference, where output length is \textit{uncertain} by nature and determined by when the end-of-sequence (EOS) token is sampled. Hence, the output length of each request should be fitted with a distribution rather than a single value. With an in-depth analysis of empirical data and the stochastic decoding process, we observe that output length follows a heavy-tailed distribution and can be fitted with the log-t distribution. On this basis, we propose a simple metric called Tail Inflated Expectation (TIE) to replace the output length in SJF scheduling, which adjusts the expectation of a log-t distribution with its tail probabilities to account for the risk that a request generates long outputs. To evaluate our TIE scheduler, we compare it with three strong baselines, and the results show that TIE reduces the per-token latency by $2.31\times$ for online inference and improves throughput by $1.42\times$ for offline data generation.

Feature Resemblance: Towards a Theoretical Understanding of Analogical Reasoning in Transformers
Ruichen Xu, Wenjing Yan, Ying-Jun Angela Zhang
Understanding reasoning in large language models is complicated by evaluations that conflate multiple reasoning types. We isolate analogical reasoning, where a model transfers an attribute between entities that share known properties, and study when such transfer can emerge from training. To make the problem analytically tractable, we study a minimal transformer-style abstraction that isolates how learned representations support analogical reasoning. Within this setting, we prove three key results. First, joint training on similarity and attribution premises enables analogical reasoning through aligned representations. Second, sequential training succeeds only when similarity structure is learned before specific attributes, revealing a curriculum asymmetry. Third, in our stylized setting, two-hop reasoning $(a \to b, b \to c \Rightarrow a \to c)$ can be viewed as analogical reasoning with identity bridges $(b=b)$, which appear explicitly in training data. Together, these results reveal a unified mechanism: entities with shared properties become aligned in representation space, enabling property transfer through feature resemblance. Experiments with architectures up to 8B parameters show qualitative agreement with the theory and suggest that representational geometry plays an important role in analogical reasoning beyond the stylized model.

Decoupling The "What" and "Where" With Polar Coordinate Positional Embedding
Anand Gopalakrishnan, Róbert Csordás, Jürgen Schmidhuber, Michael Curtis Mozer
The attention mechanism in a Transformer architecture matches key to query based on both content—the what—and position in a sequence—the where. We present an analysis indicating that what and where are entangled in the popular rotary position embedding (RoPE). This entanglement can impair performance particularly when decisions require independent matches on these two factors. We propose an improv

ement to RoPE, which we call Polar Coordinate Position Embedding or PoPE, that e liminates the what-where confound. PoPE is far superior on a diagnostic task req uiring indexing solely by position or by content. On autoregressive sequence mod eling in music, genomic, and natural language domains, Transformers using PoPE a s the positional encoding scheme outperform baselines using RoPE with respect to evaluation loss (perplexity) and downstream task performance. On language model ing, these gains persist across model scale, from 124M to 774M parameters. Cruci ally, PoPE shows strong zero-shot length extrapolation capabilities compared not only to RoPE but even a method designed for extrapolation, YaRN, which requires additional fine tuning and frequency interpolation.

Speculative Sampling For Faster Molecular Dynamics
Arthur Kosmala, Stephan Günnemann, Meng Gao, Brandon M. Wood
Molecular dynamics (MD) is a key tool for simulating the dynamical behavior of a tomic systems. However, MD is inherently serial, which makes it difficult to inc rease single-system throughput with concurrent compute. To address this, we intr oduce **L**angevin **S**peculative **D**ynamics (**LSD**), a distributed and mod el-agnostic speculative sampler for accelerating MD *without adding relative err or*. Inspired by speculative methods in language and diffusion modeling, LSD use s a draft model to propose fast simulation steps and verifies them in parallel w ith a slower target model, applying a transport map from the draft to the target distribution. We extend speculative sampling to second-order Langevin dynamics, derive the achievable speedup as a function of physical parameters, show that L SD generalizes across different systems and draft-target combinations with a 3-9 x speedup, and confirm theoretically and empirically that LSD samples trajectori es from the same distribution as its target model.

Mobility-Embedded POIs: Learning What A Place Is and How It Is Used from Human M ovement
Maria Despoina Siampou, Shushman Choudhury, Shang-Ling Hsu, Neha Arora, Cyrus Sh ahabi
Recent progress in geospatial foundation models highlights the importance of lea rning general-purpose representations for real-world locations, particularly poi nts-of-interest (POIs) where human activity concentrates. Existing approaches, h owever, focus primarily on place identity derived from static textual metadata, or learn representations tied to trajectory context, which capture movement regu larities rather than how places are actually used (i.e., POI's function). We arg ue that POI function is a missing but essential signal for general POI represent ations. We introduce Mobility-Embedded POIs (ME-POIs), a framework that augments POI embeddings derived, from language models with large-scale human mobility da ta to learn POI-centric, context-independent representations grounded in real-wo rld usage. ME-POIs encodes individual visits as temporally contextualized embedd ings and aligns them with learnable POI representations via contrastive learning to capture usage patterns across users and time. To address long-tail sparsity, we propose a novel mechanism that propagates temporal visit patterns from nearb y, frequently visited POIs across multiple spatial scales. We evaluate ME-POIs o n five newly proposed map enrichment tasks, testing its ability to capture both the identity and function of POIs. Across all tasks, augmenting text-based embed dings with ME-POIs consistently outperforms both text-only and mobility-only bas elines. Notably, ME-POIs trained on mobility data alone can surpass text-only mo dels on certain tasks, highlighting that POI function is a critical component of accurate and generalizable POI representations.

Bridging the Knowledge-Prediction Gap in LLMs on Multiple-Choice Questions
Yoonah Park, Haesung Pyun, Yohan Jo
While large language models (LLMs) perform strongly on diverse tasks, their trus tworthiness is limited by erratic behavior that is unfaithful to their internal knowledge. In particular, LLMs often fail on multiple-choice questions (MCQs) ev en if they encode correct answers in their hidden representations, revealing a m isalignment between internal knowledge and output behavior. We investigate and m

itigate this *knowledge-prediction gap* on MCQs through a three-step analysis of hidden representations. First, we quantify the prevalence and magnitude of the gap across models and datasets. Second, we provide a geometric interpretation by identifying distinct *knowledge* and *prediction* subspaces in the residual str eam. Third, we introduce **KAPPA**, a lightweight inference-time intervention th at aligns the two subspaces within the residual stream to reduce the knowledge-p rediction gap. Our results provide a geometric and interpretable explanation of the knowledge-prediction gap in LLMs. Furthermore, KAPPA effectively reduces the gap across diverse MCQ benchmarks and models, and generalizes to free-form sett ings.

Towards Theoretical Understanding of Transformer Test-Time Computing: Investigat ion on In-Context Linear Regression
Xingwu Chen, Miao Lu, Beining Wu, Difan Zou
Scaling test-time computation during language model inference, such as generatin g intermediate thoughts or sampling multiple candidate answers, has proven effec tive in improving model performance.
While these techniques inherently rely on the stochastic nature of inference to explore diverse reasoning paths, prior theoretical works typically build on a *d eterministic decoding* framework, overlooking the stochastic nature of practical language model inference.
This work takes an initial step to bridge this gap by establishing a new theoret ical framework, incorporating *randomness and sampling* directly into the decodi ng analysis.
To demonstrate the framework's effectiveness, we apply it to the canonical in-co ntext linear regression task with continuous and binary coefficients, simulating decoding via noise injection and sampling to analyze widely adopted inference t echniques.
We validate our theoretical findings through numerical simulations, with additio nal experiments on real-world tasks substantiating the framework's potential for practical applications.

Critique-Guided Distillation for Robust Reasoning via Refinement
Berkcan Kapusuzoglu, Supriyo Chakraborty, Zain Sarwar, Chia-Hsuan Lee, Sambit Sa hu
Supervised fine-tuning with expert demonstrations often produces models that imi tate outputs without internalizing the reasoning processes needed for robust gen eralization. While critique-based approaches show promise, training models to ge nerate critiques directly, such as Critique Fine-Tuning (CFT), can lead to outpu t-format drift and degradation of general capabilities. We propose $\textbf{C}$r itique-$\textbf{G}$uided $\textbf{D}$istillation (CGD), a training framework tha t decouples critique consumption from critique generation. During fine-tuning, t he student is trained to refine flawed responses conditioned on teacher critique s. CGD treats critiques as a $\textit{training-time-only}$ supervision signal, e ncouraging internalization of error-aware reasoning: critiques guide learning bu t are absent at inference. Across five model families, CGD consistently outperfo rms CFT and standard distillation on mathematical reasoning benchmarks, yielding 7\% average improvements and gains of up to +15.0\% on AMC23 and +12.2\% on MAT H-500. On challenging competition problems such as AIME24 and AIME25, CGD achiev es substantially higher Pass@1 and stronger performance at low Pass@k, indicatin g improved reasoning quality per sample. Importantly, CGD preserves general inst ruction-following capabilities where CFT degrades significantly ($-$21.3\% on IF Eval). These results position CGD as a practical and compute-efficient intermedi ate training paradigm for reasoning-centric tasks without introducing architectu ral inference-time overhead.

PVDepth: Panoramic Video Depth Estimation via Geometry-Aware Spatiotemporal Adap tation
Chuanxin Song, Peixi Peng
Panoramic video depth estimation is pivotal for applications such as Virtual Rea

lity and World Models. However, advancements in this field are impeded by two pr
imary obstacles: the scarcity of large-scale training data and the unique spatio
temporal challenges of Equirectangular Projection (ERP), which hinder the direct
 transfer of perspective models.
In this paper, we first present **PanoCARLA**, a large-scale synthetic RGB-D pan
oramic video dataset, featuring natural motion trajectories and drone-like roami
ng perspectives.
Building on this foundation, we propose **PVDepth**, an end-to-end framework ada
pted from perspective video depth models.
To tackle ERP-specific geometric distortions and consequent non-linear temporal
dynamics, we introduce two core mechanisms: (1) A *Progressive Sphere-aware Nois
e Initialization* strategy that anneals the noise distribution from planar to sp
herical, guiding the model to adapt to non-uniform information density; and (2)
A *Cube-rectified Temporal Modeling* module that incorporates an auxiliary cubem
ap temporal branch to rectify non-linear temporal dynamics in the ERP domain.
Extensive experiments demonstrate that PVDepth achieves superior performance, ge
nerating geometrically accurate and temporally consistent depth sequences. Code
and data will be released at https://github.com/ChuanxinSong/PVDepth.

VLM-RobustBench: A Comprehensive Benchmark for Robustness of Vision-Language Mod
els

Rohit Saxena, Alessandro Suglia, Pasquale Minervini

Vision-language models (VLMs) achieve strong performance on standard, high-quali
ty datasets, but we still do not fully understand how they perform under real-wo
rld image distortions. We present VLM-RobustBench, a benchmark spanning 49 augme
ntation types across noise, blur, weather, digital, and geometric perturbations,
 evaluated under graded severities (low/mid/high) and binary transforms, yieldin
g 133 corrupted settings. We evaluate 15 VLMs from five families, including prop
rietary GPT-5.4-mini, on two complementary benchmarks: MMBench (visually grounde
d) and MMMU-Pro (reasoning-oriented). Our results reveal that visual severity is
 a weak predictor of difficulty: low-severity spatial perturbations often degrad
e performance more than visually severe photometric corruptions. In particular,
low-severity glass blur reduces MMBench accuracy by about 8 pp on average across
 models, while the largest drops arise from resampling and geometric distortions
 (e.g., upsample, elastic transform), reaching up to 34 pp. Overall, our finding
s suggest current VLMs are semantically strong but spatially fragile, motivating
 the definition of novel robustness evaluation protocols and training regimes th
at emphasize resampling and geometric invariance.

RoCA: Robust Cross-Domain End-to-End Autonomous Driving

Rajeev Yasarla, Shizhong Han, Hsin-Pai Cheng, Apratim Bhattacharyya, Shweta Maha
jan, Litian Liu, Yunxiao Shi, Risheek Garrepalli, Hong Cai, Fatih Porikli

End-to-end (E2E) autonomous driving has recently emerged as a new paradigm, offe
ring significant potential. However, few studies have looked into the practical
challenge of deployment across domains (e.g., cities). Although several works ha
ve incorporated Large Language Models (LLMs) to leverage their open-world knowle
dge, LLMs do not guarantee cross-domain driving performance and may incur prohib
itive retraining costs during domain adaptation. In this paper, we propose RoCA,
 a novel framework for robust cross-domain E2E autonomous driving. RoCA formulat
es the joint probabilistic distribution over the tokens that encode ego and surr
ounding vehicle information in the E2E pipeline. Instantiating with a Gaussian p
rocess (GP), RoCA learns a set of basis tokens with corresponding trajectories,
which span diverse driving scenarios. Then, given any driving scene, it is able
to probabilistically infer the future trajectory. By using RoCA together with a
base E2E model in source-domain training, we improve the generalizability of the
 base model, without requiring extra inference computation. In addition, RoCA en
ables robust adaptation on new target domains, significantly outperforming direc
t finetuning. We extensively evaluate RoCA on various cross-domain scenarios and
 show that it achieves strong domain generalization and adaptation performance.

UniCode: Augmenting Evaluation for Code Reasoning
Xinyue Zheng, Haowei Lin, Shaofei Cai, Yaodong Yang, Zilong Zheng, Yitao Liang
Current coding benchmarks often overstate Large Language Model (LLM) capabilities due to static paradigms and data contamination, allowing models to exploit statistical shortcuts rather than genuine reasoning. To address this, we introduce UniCode, a generative evaluation framework that systematically probes LLM reasoning boundaries via: (1) multi-dimensional augmentation operators to create diverse algorithmic variants; (2) a scalable test generation pipeline achieving 94.5\% correctness without human-written solutions; and (3) fine-grained diagnostic metrics for rich error signals. Our evaluation of state-of-the-art models reveals a significant 31.2\% performance collapse. Critically, we observe a high variance across different reasoning axes, revealing a profound fragility under structural shifts despite surface-level robustness. Furthermore, we identify a ``seed-problem regression," where models fail by defaulting to memorized seed logic and inefficient complexities. Our evaluation code is publicly available at \url{https://github.com/grandsmile/UniCode}.

MoRGen: Mixture-of-Resolutions Generative Forecasting for Irregularly Sampled Medical Time-Series Data
Nassim Oufattole, Matthew B.A. McDermott, Collin Stultz
Autoregressive generative models for irregularly sampled clinical time-series data are increasingly used for zero-shot risk forecasting. Prior work typically adopts a single fine-grained discretization of time, where tokens are generated at one fixed, predetermined temporal resolution. We demonstrate that the zero-shot accuracy of individual generative forecasters varies with temporal resolution: performance can degrade when the model resolution is poorly matched to the temporal dynamics of the endpoint being evaluated. We then propose MoRGen (Mixture-of-Resolutions Generation), which fuses forecasts from generative experts trained at multiple temporal resolutions using a low-capacity task-specific mixture, improving performance across tasks with different temporal dynamics. Across multiple horizons and outcomes on three independent clinical datasets, MoRGen achieves lower binary cross-entropy (BCE) and statistically significant AUROC gains over autoregressive generative models that forecast tokens at a fixed temporal resolution.
****
QTALE: Quantization-Robust Token-Adaptive Layer Execution for LLMs
KangHyun Noh, Jinheon Choi, Yulhwa Kim
Large language models (LLMs) demand substantial computational and memory resources, posing challenges for efficient deployment. Two complementary approaches have emerged to address these issues: token-adaptive layer execution, which reduces floating-point operations (FLOPs) by selectively bypassing layers, and quantization, which lowers memory footprint by reducing weight precision. However, naively integrating these techniques leads to additional accuracy degradation due to reduced redundancy in token-adaptive models.
We propose QTALE (Quantization-Robust Token-Adaptive Layer Execution for LLMs), a novel framework that enables seamless integration of token-adaptive execution with quantization while preserving accuracy. Conventional token-adaptive methods reduce redundancy in two ways: (1) by limiting the diversity of training paths explored during fine-tuning, and (2) by lowering the number of parameters actively involved in inference. To overcome these limitations, QTALE introduces two key components:
(1) a training strategy that ensures diverse execution paths are actively explored during fine-tuning, and
(2) a post-training mechanism that allows flexible adjustment of the execution ratio at inference to reintroduce redundancy when needed.
Experimental results show that QTALE enables seamless integration of token-adaptive layer execution with quantization, showing no noticeable accuracy difference, with the gap to quantization-only models kept below 0.5\% on CommonsenseQA benchmarks.
By combining token-adaptive execution for FLOPs reduction and quantization for m

emory savings, QTALE provides an effective solution for efficient LLM deployment

Neuro-evolutionary Continual Reinforcement Learning
Pengyi Li, Hongyao Tang, Yifu Yuan, YAN ZHENG, Xin Xu, Jianye HAO
Deploying robots in open-ended real-world environments demands continual learnin
g capabilities to adapt to an ever-expanding range of tasks. This requires retai
ning previously acquired skills without forgetting while effectively leveraging
prior knowledge to learn new ones. Inspired by neuroscience, we propose **N**eur
o-**e**volutionary **C**ontinual **R**einforcement **L**earning (**Nevo-CRL**).
Nevo-CRL maintains a fixed-capacity monolithic policy network, solving tasks by
optimizing inter-layer connectivity and neuron parameters.
For each new task, Nevo-CRL constructs a mask population to selectively activate
 the outputs of each hidden layer, thereby forming a task-specific policy popula
tion. Upon completing each task, the best-performing mask is stored, and its act
ivated neurons are frozen to prevent catastrophic forgetting. To facilitate know
ledge transfer, Nevo-CRL reuses neurons from acquired skills based on semantic s
imilarity between tasks, while dynamically allocating additional neurons for tas
k-specific adaptation.
In the learning process, Nevo-CRL iteratively adjusts masks via importance-guide
d crossover to optimize the policy network connectivity. To improve neuron utili
zation, we prune low-activity connections to recycle neurons. Experiments demons
trate that Nevo-CRL achieves state-of-the-art performance among continual RL met
hods.
The code is available at [https://github.com/yeshenpy/Nevo-CRL](https://github.c
om/yeshenpy/Nevo-CRL).

Explainable Forensics of Manipulated Segments in Untrimmed Long Videos
Yue Feng, Jingjing Li, Qijia Lu, Wei Ji, Jingrou Zhang, Fei Shen, Xiao Li, Yizhe
n Jia, Qiang Chen, Limin Wang, Wentong Li, Jie Qin
The rapid advancement of AI-driven video generation has transformed content crea
tion, while simultaneously increasing the risk of misinformation through localiz
ed manipulations in long-form videos. Existing video forensic methods predominan
tly operate on short, independent clips, and thus fail to capture realistic scen
arios where AI-generated content is sparsely embedded within otherwise authentic
 footage. To bridge this gap, we formulate the task of Temporal AI-Generated Seg
ment Localization and Explanation, which targets authenticity detection, tempora
l localization, and interpretable analysis of manipulated segments in untrimmed
long videos. We further introduce TASLE, a large-scale benchmark comprising 12,4
72 untrimmed videos with diverse manipulation patterns and rich annotation signa
ls, including temporal boundaries, authenticity labels, and segment-level ration
ales. In addition, we propose MSLoc, a coarse-to-fine forensic baseline that com
bines a boundary-sensitive proposal generation module for efficient long-video s
canning with an MLLM-based refinement module for precise boundary localization a
nd interpretable reasoning. Experiments validate the effectiveness of the propos
ed baseline, highlighting the importance of segment-level explainable forensics
for long-form AI-generated video analysis. Dataset and code will be made publicl
y available.

TritonGym: A Benchmark for Agentic LLM Workflows in Triton GPU Code Generation
Yue Guan, Yichen Lin, Xu Zhao, Jianzhu Yao, Xinwei Qiang, Zhongkai Yu, Pramod Vi
swanath, Yufei Ding, Adnan Aziz
Large language models (LLMs) can already draft plausible Triton kernels, yet mos
t existing evaluations still focus on single-shot generation and underplay tool
use and feedback. We introduce *TritonGym*, a benchmark and orchestration framew
ork for evaluating agentic workflows in GPU code generation. *TritonGym* standar
dizes access to a set of code generation tools via function-calls, separating in
trinsic model capability from workflow design and enabling fair, apples-to-apple
s comparison. The benchmark spans a maintained operator set, community samples,
out-of-distribution tasks, and DSL extensions, ensuring both generality and exte

nsibility. By providing a common orchestration and evaluation framework, *Triton Gym* democratizes the development of GPU coding agents, supports practical adoption of agent-generated kernels, and facilitates progress on advanced agentic systems.

Bilevel Optimization over Saddle Points of Zero-Sum Markov Games
Zihao Zheng, Irwin King, Songtao Lu
Reinforcement learning (RL) often has a hierarchical structure, where an upper-level (UL) learner selects model parameters and a lower-level (LL) decision-making process responds, naturally leading to a bilevel optimization problem. Most existing bilevel RL methods assume a single-policy LL Markov decision process (MDP), and therefore fail to capture competitive structures arising in applications such as incentive design, where multiple policies interact. We study bilevel optimization problems in which the LL problem is a regularized min–max zero-sum Markov game and the UL objective is optimized through the saddle-point equilibrium induced by the LL game. In this work, we propose penalty-augmented Nikaido–Isoda descent–ascent (PANDA), a penalty-based first-order policy-gradient method based on the Nikaido–Isoda function. By exploiting the min–max game structure, PANDA avoids computing UL hypergradients and does not require second-order information. We prove that PANDA converges to stationary points without convexity assumptions on either the UL or LL objectives. Moreover, PANDA reaches an ϵ-stationary point in $\tilde{\mathcal{O}}(\epsilon^{-1})$ iterations with sample complexity $\tilde{\mathcal{O}}(\epsilon^{-3})$, matching the best-known rates for bilevel RL with single-policy LL MDPs. Experiments demonstrate the superior performance of PANDA over closely related baselines.

CLEAR: Context-Aware Learning with End-to-End Mask-Free Inference for Adaptive Video Subtitle Removal
Qingdong He, Chaoyi Wang, Peng Tang, Yifan Yang, Xiaobin Hu
Video subtitle removal is essential for content localization and media re-editing, yet existing mask-guided diffusion methods face critical limitations: training inefficiency requiring extensive annotations and full model fine-tuning, inference complexity demanding explicit mask sequences, and static prior utilization unable to adapt to quality variations. We present CLEAR (Context-aware Learning for End-to-end Adaptive subtitle Removal), a lightweight adapter-based framework addressing these challenges through three technical innovations. First, self-supervised prior learning (Stage I) extracts occlusion guidance from video pairs using pixel differences as weak supervision, eliminating annotation dependency while learning generalizable subtitle features across languages. Second, LoRA-based adaptive refinement (Stage II) enables parameter-efficient training that preserves pre-trained visual priors while achieving true mask-free end-to-end inference without external detection modules. Third, adaptive focal weighting dynamically adjusts prior influence based on local quality assessment, effectively handling diverse subtitle styles and noisy guidance signals. Extensive experiments demonstrate CLEAR's superior performance in multilingual subtitle removal while requiring only 0.77% trainable parameters, establishing a new paradigm for efficient video text removal without inference-time mask dependencies.
****
TPV: Parameter Perturbations Through the Lens of Test Prediction Variance
Devansh Arpit
We introduce test prediction variance (TPV)—the first-order sensitivity
of a trained model's outputs to parameter perturbations—as a unifying framework for analyzing post-training robustness. TPV's trace form $\mathrm{Tr}(H_{\mathrm{eff}}C)$ separates the geometry of the trained model H_{eff} from the perturbation covariance C, placing SGD noise, label noise, quantization, and pruning under
a single lens. The resulting expressions recover the wide-minima hypothesis for SGD and quantization noise, and yield a distinct Jacobian-spectral characterization for label noise connecting label-noise TPV with benign overfitting in nonlinear networks.

Theoretically, we prove that training-set TPV converges to its test-set counterp art in the overparameterized limit, irrespective of generalization performance, providing the first result that prediction variance under local parameter pertur bations can be inferred from training inputs alone. Empirically, this stability holds far more broadly, including at very low widths. Further, TPV correlates we ll with test loss, enabling practical applications: JBR, a label-free pruning cr iterion derived from TPV geometry matching state-of-the-art baselines; and train ing-set based model selection signal for in-distribution and transfer learning s cenarios. \href{https://github.com/devansharpit/TPV/tree/main}{Code Available He re}

Lagrangian Perturbation Diffusion Steering: Latent Reinforcement Learning for Ge nerative Policies

Hikmet Simsir, Ozgur S. Oguz

Behavior cloning with high-capacity generative policies achieves strong imitatio n performance, but is often limited by demonstration coverage and distribution s hift. Direct reinforcement learning fine-tuning can improve performance, but upd ating large action decoders is frequently unstable and sample inefficient. We pr opose **Lagrangian Perturbation Diffusion Steering (LP-DS)**, a lightweight adap tation method that improves a frozen generative policy by learning a compact noi se-space perturbation before decoding. LP-DS optimizes this perturbation with a Lagrangian trust-region objective, improving downstream value while constraining deviation from the latent prior. Across RoboMimic manipulation, OpenAI Gym loco motion, and Adroit dexterous manipulation benchmarks, LP-DS improves sample effi ciency, success, and return while maintaining higher action-space entropy than u nconstrained noise-space steering, with return improvements of up to 25\% over p rior baselines. Additional evaluations with flow-matching backbones, a large vis ion-language-action model, and physical Franka deployment show that LP-DS is not limited to compact diffusion policies or simulated benchmarks. Project page: ht tps://sites.google.com/view/lp-ds/home.

The Hippocampal Place Field Gradient: A Bio-inspired Framework Building Multisca le Representation for Better Sample Efficiency

ZHOU Shujun, Junrong Qi, Guozhang Chen

The hippocampus encodes space through a striking gradient of place field sizes a long its dorsal-ventral axis, yet the principles generating this continuous grad ient from discrete grid cell inputs remain unclear. We propose a unified theoret ical framework establishing how multiscale hippocampal place fields arise from t he frequency-dependent decay of grid cell projections. Functionally, this organi zation establishes an inductive bias in the population code, managing a fundamen tal trade-off between spatial precision and sample efficiency. Translating this insight to artificial neural networks, we incorporate a hippocampus-inspired pos itional embedding (HIPE) into the Transformer architecture to induce multi-scale representation. Experimental results confirm that this mechanism effectively im proves data efficiency. Our work establishes a link between neural connectivity, activity patterns, and learning, suggesting a principled approach to utilizing multi-scale representations for sample-efficiency learning. Our codes are availa ble at https://github.com/AIogry/relative_PE.

Spurious Correlation Learning in Preference Optimization: Mechanisms, Consequenc es, and Mitigation via Tie Training

Christian Moya, Alex Semendinger, Guang Lin, Elliott Thornley

Preference learning methods like Direct Preference Optimization (DPO) are known to induce reliance on spurious correlations, leading to sycophancy and length bi as in today's language models and potentially severe goal misgeneralization in f uture systems. In this work, we provide a unified theoretical analysis of this p henomenon, characterizing the mechanisms of spurious learning, its consequences on deployment, and a provable mitigation strategy. Focusing on log-linear polici es, we show that standard preference-learning objectives induce reliance on spur

ious features at the population level through two channels: mean spurious bias a
nd causal-spurious correlation leakage. We then show that this reliance creates
an irreducible vulnerability to distribution shift: more data from the same trai
ning distribution fails to reduce the model's dependence on spurious features. T
o address this, we propose *tie training*, a data augmentation strategy using ti
es (equal-utility preference pairs) to introduce data-driven regularization. We
demonstrate that this approach selectively reduces spurious learning without deg
rading causal learning. Finally, we validate our theory on log-linear models and
 provide empirical evidence that both the spurious learning mechanisms and the b
enefits of tie training persist for neural networks and large language models.

See What Matters: Differentiable Grid Sample Pruning for Generalizable Vision-La
nguage-Action Model
Yixu Feng, Zinan Zhao, Yanxiang Ma, Chenghao Xia, Chengbin Du, Yunke Wang, Chang
 Xu
Vision-Language-Action (VLA) models have shown remarkable promise in robotics ma
nipulation, yet their high computational cost hinders real-time deployment. Exis
ting token pruning methods suffer from a fundamental trade-off: aggressive compr
ession using pruning inevitably discards critical geometric details like contact
 points, leading to severe performance degradation. This forces a compromise, li
miting the achievable compression rate and thus the potential speedup. We argue
that breaking this trade-off requires rethinking compression as a geometry-aware
, continuous token resampling in the vision encoder.
To this end, we propose the *Differentiable Grid Sampler (GridS)*, a plug-and-pl
ay module that performs task-aware, continuous resampling of visual tokens in VL
A. By adaptively predicting a minimal set of salient coordinates and extracting
features via differentiable interpolation, GridS preserves essential spatial inf
ormation while achieving drastic compression (with fewer than 10\% original visu
al tokens). Experiments on both LIBERO benchmark and a real robotic platform dem
onstrate that validating the lowest feasible visual token count reported to date
,
GridS achieves a 76\% reduction in FLOPs with no degradation in the success rate
. The code is available at https://github.com/Fediory/Grid-Sampler.

Self-Supervised Flow Matching for Scalable Multi-Modal Synthesis
Hila Chefer, Patrick Esser, Dominik Lorenz, Dustin Podell, Vikash Raja, Vinh Ton
g, Antonio Torralba, Robin Rombach
Strong semantic representations improve the convergence and generation quality o
f diffusion and flow models. Existing approaches largely rely on external models
, which require separate training, operate on misaligned objectives, and exhibit
 unexpected scaling behavior. We argue that this dependence arises from the mode
l's training objective, which poses a denoising task with little incentive to le
arn semantic representations. We introduce *Self-Flow*: a self-supervised flow m
atching paradigm that integrates representation learning within the generative f
ramework. Our key mechanism, *Dual-Timestep Scheduling*, applies heterogeneous n
oise levels across tokens, creating an information asymmetry that forces the mod
el to infer missing information from corrupted inputs. This drives learning stro
ng representations alongside generative capabilities without external supervisio
n. Our method generalizes across modalities and enables multi-modal training whi
le following expected scaling laws, achieving superior image, video, and audio g
eneration.

GSRQ: Gain-Shape Residual Quantization for Sub-1-bit KV Cache
Soosung Kim, Minjae Park, Eui-Young Chung, Jaeyong Chung
The deployment of Large Language Models (LLMs) with extended context windows is
increasingly constrained by the linear growth of Key-Value (KV) cache memory.
Vector Quantization (VQ), particularly Residual Quantization (RQ), is a promisin
g approach for pushing KV cache storage toward the sub-1-bit regime by progressi
vely encoding residuals with small codebooks.
However, most VQ methods still rely on standard ℓ_2 K-means as the core c

odebook-learning primitive.
We identify a subtle high-dimensional issue of this primitive: Euclidean centroid averaging can induce centroid shrinkage, which weakens the angular alignment term in the ℓ_2 distortion and makes directional preservation harder.
To address this issue, we propose Gain-Shape K-means (GSKM), a drop-in replacement for K-means that improves directional fidelity while matching, and in some regimes improving, ℓ_2 distortion.
We then build Gain-Shape Residual Quantization (GSRQ) by incorporating a weighted extension of GSKM into an RQ pipeline.
On LLaMA-3-8B, GSRQ substantially improves over strong KV cache quantization baselines across bit rates.
At 1-bit, it improves the average accuracy across LongBench tasks from 11.34 to 33.54, a gain of 22.20 percentage points over VQLLM.

Multi-Level Strategic Classification: Incentivizing Improvement through Promotion and Relegation Dynamics
Ziyuan Huang, Lina Alkarmi, Mingyan Liu
Strategic classification studies the problem where self-interested individuals or agents manipulate their response to obtain favorable decision outcomes made by classifiers, typically turning to dishonest actions when they are less costly than genuine efforts. While existing studies on sequential strategic classification primarily focus on optimizing dynamic classifier weights, we depart from these weight-centric approaches by analyzing the design of classifier thresholds and difficulty progression within a multi-level promotion-relegation framework. Our model captures the critical inter-temporal incentives driven by an agent's farsightedness, skill retention, and a "leg-up" effect where qualification and attainment can be self-reinforcing. We characterize the agent’s optimal long-term strategy and demonstrate that a principal can design a sequence of thresholds to effectively incentivize honest effort. Crucially, we prove that under mild conditions, this mechanism enables agents to reach arbitrarily high levels solely through genuine improvement efforts.

Efficient Reasoning with Hidden Thinking
Xuan Shen, Yizhou Wang, Yufa Zhou, Xiangxi Shi, Pu Zhao, Yanzhi Wang, Jiuxiang Gu
Chain-of-Thought (CoT) reasoning has become a powerful framework for improving complex problem-solving capabilities in Multimodal Large Language Models (MLLMs). However, the verbose nature of textual reasoning introduces significant inefficiencies. In this work, we propose**Heima** (as hidden llama), an effective CoT compression framework that condenses lengthy CoTs into a small set of abstract thinking tokens, preserving essential reasoning while removing redundancy. We then conduct a theoretical analysis from an information-theoretic perspective, quantifying the information gap induced by compression, showing that reasoning capability is preserved when non-trivial mutual information is retained. To further explore and quantify this information gap, we design the adaptive interpreter that maps thinking tokens back to variable-length textual sequences, thereby reconstructing the reasoning process. Experiments across diverse reasoning benchmarks demonstrate that Heima improves reasoning efficiency, while maintaining or even achieving better zero-shot accuracy. Moreover, the interpreter reconstructs coherent reasoning progresses from compressed thinking tokens, revealing that the information gap is minimal and validating the effectiveness of the proposed framework. This work paves the way for scalable latent reasoning models and advances our understanding of efficient reasoning processes in large models. Code: https://github.com/shawnricecake/Heima

3ViewSense: Spatial and Mental Perspective Reasoning from Orthographic Views in Vision-Language Models
Shaoxiong Zhan, Yanlin Lai, Zheng Liu, Lin Hai, Shen Li, Xiaodong Cai, Zijian Lin, Wen Huang, Hai-Tao Zheng
Current Large Language Models have achieved Olympiad-level logic, yet Vision-Lan

guage Models paradoxically falter on elementary spatial tasks like block countin g. This capability mismatch reveals a critical "spatial intelligence gap," where models fail to construct coherent 3D mental representations from 2D observation s. We uncover this gap via diagnostic analyses showing the bottleneck is a missi ng view-consistent spatial interface rather than insufficient visual features or weak reasoning. To bridge this, we introduce **3ViewSense**, a framework that g rounds spatial reasoning in Orthographic Views. Drawing on engineering cognition , we propose a "Simulate-and-Reason" mechanism that decomposes complex scenes in to canonical orthographic projections to resolve geometric ambiguities. By align ing egocentric perceptions with these allocentric references, our method facilit ates explicit mental rotation and reconstruction. Empirical results on spatial r easoning benchmarks demonstrate that our method significantly outperforms existi ng baselines, with consistent gains on occlusion-heavy counting and view-consist ent spatial reasoning. The framework also improves the stability and consistency of spatial descriptions, offering a scalable path toward stronger spatial intel ligence in multimodal systems.

Counterfactual Occlusion-Aware Learning via Visibility Intervention for LiDAR An omaly Detection

Longyu Yang, Jun Liu, Yap-Peng Tan, Fumin Shen, Heng Tao Shen, Xiaofeng Zhu, Pin g Hu

LiDAR point cloud anomaly detection is critical for autonomous system safety, ye t most existing methods rely only on visible measurements, overlooking occlusion as a structured consequence of the LiDAR sensing process. We argue that anomali es are characterized not only by what is observed, but also by the spatial voids they create, which alter occlusion patterns and volumetric visibility. We propo se Counterfactual Occlusion-Visibility Anomaly Learning (COVAL), a framework tha t intervenes on volumetric visibility during training. Using physics-conformed s ynthetic anomaly construction, COVAL generates paired factual and counterfactual observations with identical scene geometry but different occlusion patterns. Th en, we introduce two complementary objectives: Visibility-Variant Counterfactual Reconstruction, which models occlusion-induced missing regions, and Visibility-Invariant Counterfactual Consistency, which enforces stable representations acro ss visibility changes. Together, these objectives isolate anomaly-induced struct ural missingness and in turn refine representation of normal scenes, thus improv ing anomaly sensitivity at test time. Experiments on standard LiDAR anomaly segm entation benchmarks show that COVAL achieves state-of-the-art performance.

Autobidding Auctions with LLM-Powered Creatives

Bingzhe Wang, Bowei Zhang, Changyuan Yu, Qi Qi

The integration of Large Language Models (LLMs) into ad auctions for dynamic cre ative enhancement presents a paradigm shift, yet introduces significant computat ional costs disrupting traditional mechanism design. This paper provides a compr ehensive game-theoretic and algorithmic framework for such LLM-augmented auction s. We model the system as a dynamic Stackelberg game where the platform (leader) strategically invests in creative enhancement to maximize net revenue, while au tobidding agents (followers) respond to enhanced ad qualities under budget const raints. To endogenize inference costs, we propose the Platform-Investment Mechan ism (PIM). We develop the Online Dual-Descent Bidding with Regularization (ODDB-R) algorithm for agents to learn optimal bidding strategies in this non-stationa ry environment. For the platform, we formulate the investment problem as a conti nuous control task and solve it using a Two-Timescale Stackelberg Learning with Proximal Policy Optimization (TTSL-PPO) algorithm, which provably converges to a Stackelberg Stationary Point. Extensive experiments on large-scale real-world d atasets and state-of-the-art LLMs demonstrate that our framework significantly o utperforms heuristic baselines in revenue, social welfare, and user engagement.

Adaptive Multi-Round Allocation with Stochastic Arrivals

Yuqi Pan, Davin Choo, Haichuan Wang, Milind Tambe, Alastair van Heerden, Cheryl Johnson

We study a sequential resource allocation problem motivated by adaptive network recruitment, in which a limited budget of identical resources must be allocated over multiple rounds to individuals with stochastic referral capacity. Successful referrals endogenously generate future decision opportunities while allocating additional resources to an individual exhibits diminishing returns. We first show that the single-round allocation problem admits an exact greedy solution based on marginal survival probabilities. In the multi-round setting, the resulting Bellman recursion is intractable due to the stochastic, high-dimensional evolution of the frontier. To address this, we introduce a population-level surrogate value function that depends only on the remaining budget and frontier size. This surrogate enables an exact dynamic program via truncated probability generating functions, yielding a planning algorithm with polynomial complexity in the total budget. We further analyze robustness under model misspecification, proving a multi-round error bound that decomposes into a tight single-round frontier error and a population-level transition error. Finally, we evaluate our method on real-world inspired recruitment scenarios.

What Language is This? Ask Your Tokenizer.
Clara Meister, Ahmetcan Yavuz, Pietro Lesci, Tiago Pimentel
Language Identification (LID) is an important component of many multilingual natural language processing pipelines, where it facilitates corpus curation, training data analysis, and cross-lingual evaluation of large language models. Despite near-perfect performance on high-resource languages, existing systems remain brittle in low-resource and closely related language settings. We introduce UniLID, a simple and efficient LID method based on the UnigramLM tokenization algorithm, leveraging its probabilistic framing, parameter estimation technique and inference strategy. In short, to predict a string's language label, we simply ask: under which language's unigram distribution is this string most likely? Our formulation is data- and compute-efficient, supports incremental addition of new languages without retraining existing models, and can naturally be integrated into existing language model tokenization pipelines. Empirical evaluations against widely used baselines, including fastText, GlotLID-M, and CLD3, show that UniLID achieves competitive performance on standard benchmarks, substantially improves sample efficiency in low-resource settings—surpassing 70% accuracy with as few as five labeled samples per language—and delivers large gains on fine-grained dialect identification.
****
Minimizing Mismatch Risk: A Prototype-Based Routing Framework for Zero-shot LLM-generated Text Detection
Ke Sun, Guangsheng Bao, Han Cui, Yue Zhang
Zero-shot methods detect LLM-generated text by computing statistical signatures using a surrogate model. Existing approaches typically employ a fixed surrogate for all inputs regardless of the unknown source. We systematically examine this design and find that detection performance varies substantially depending on surrogate-source alignment. We observe that while no single surrogate achieves optimal performance universally, a well-matched surrogate typically exists within a diverse pool for any given input. This finding transforms robust detection into a routing problem: selecting the most appropriate surrogate for each input. We propose DetectRouter, a prototype-based framework that learns text-detector affinity through two-stage training. The first stage constructs discriminative prototypes from white-box models; the second generalizes to black-box sources by aligning geometric distances with observed detection scores. Experiments on EvoBench and MAGE benchmarks demonstrate consistent improvements across multiple detectio

n criteria and model families.

Reasoning-preserved Efficient Distillation of Large Language Models via Activation-aware Initialization
Junlin He, Yihong Tang, Tong Nie, Guilong Li, Binyu Yang, Jinxiao Du, Lijun Sun, Wei Ma
Efficient Distillation (EDistill) compresses large language models (LLMs) by structured pruning parameters and tuning lightweight modules with high training efficiency. Although these EDistilled LLMs achieve state-of-the-art (SOTA) performance on general ability benchmarks relative to similarly sized LLMs, we identify a severe degradation in their multi-step reasoning ability, which we term reasoning collapse. We systematically analyze the geometric origins of reasoning collapse and show that the SOTA EDistill method based on width-reducing projection matrices suffers from eRank collapse, in which the effective rank (eRank) of hidden representations drops. We theoretically explain how singular values of randomly initialized projection matrices become unevenly distributed, leading to eRank collapse and thus token indistinguishability. To address this issue, we propose RED (Reasoning-preserved Efficient Distillation) for LLMs, which introduces activation-aware initialization to initialize projection matrices as channel-selection matrices, thus theoretically mitigating eRank collapse. Experiments on Llama and Qwen series demonstrate that RED substantially recovers reasoning while maintaining high training efficiency and SOTA general ability.

How Few-Shot Examples Add Up: A Causal Decomposition of Function Vectors in In-Context Learning
Entang Wang, Yiwei Wang, Aleksandra Bakalova, Michael Hahn
In-context learning (ICL) excels at new tasks from minimal examples, yet we still lack a mechanistic explanation of how few-shot prompts shape a model’s function vector (FV)--a causal activation direction that drives task behavior on the ICL query. Across tasks and models, an n-shot FV is well-approximated by a linear combination of example-level sub-FVs, suggesting additive and composable contributions from individual demonstrations. Beyond additivity, we show that models contextualize individual examples' representations based on prior examples to adaptively reweight which demonstrations dominate the FV: attention shifts toward examples that are more informative and less ambiguous under the context. Finally, a causal decomposition separates Query–Key routing from Value updates, finding that contextualization’s most consistent contributions to FV quality arise from Query–Key alignment--particularly in ambiguous settings--while Value-mediated effects are more heterogeneous. Together, these results unify additive superposition with context-dependent attention reweighting into a mechanistic, testable account of how few-shot prompts implement tasks.

Learning Coupled Continuous-Time Latent Dynamics from Irregular Events
Jiankai Zuo, Yang Zhang, Yu Zhang, Jiarui Liang, Yaying Zhang
Modeling dynamic dependencies from irregularly sampled event sequences is a fundamental challenge in modern machine learning. In many real-world systems, individual-level states evolve continuously over time while being simultaneously influenced by population-level dynamics. However, existing methods typically model these processes in isolation or rely on discrete-time approximations that fail to capture long-range temporal irregularities and sparse observations. This paper studies the problem of learning coupled continuous-time latent dynamics from irregular events, where individual event sequences and global distributional processes evolve asynchronously and interact over time. We propose a Coupled Continuous-Time Latent Dynamics (CoCLD) framework that jointly models individual latent dynamics and population-level distributional shifts, and aligns them in a continuous-time latent space. CoCLD integrates a Diffusion-based Latent Interpolator with neural ordinary differential equations, enabling principled interpolation, generation, and alignment of latent states across arbitrary time points. We show that the proposed coupling mechanism yields a consistent estimator of continuous-time latent dynamics under sparse and irregular observations. Empirical evaluatio

ns show CoCLD effectively captures dynamic dependencies and generalizes across t
asks like next-event prediction, mobility trajectory generation, and sequential
behavior modeling, indicating that learning coupled continuous-time latent dynam
ics is a powerful paradigm for irregular event sequence modeling.

EvoClaw: Evaluating AI Agents on Continuous Software Evolution
Gangda Deng, Zhaoling Chen, Zhongming Yu, Haoyang Fan, Yuhong Liu, Yuxin Yang, D
hruv Parikh, Rajgopal Kannan, Le Cong, Mengdi Wang, Qian Zhang, Viktor Prasanna,
 Xiangru Tang, Xingyao Wang
With AI agents increasingly deployed as long-running systems, it becomes essenti
al to autonomously construct and continuously evolve customized software to enab
le interaction within dynamic environments. Yet, existing benchmarks evaluate ag
ents on isolated, one-off coding tasks, neglecting the temporal dependencies and
 technical debt inherent in real-world software evolution.
To bridge this gap, we introduce DeepCommit, an agentic pipeline that reconstruc
ts verifiable Milestone DAGs from noisy commit logs, where milestones are define
d as functionally cohesive development goals.
These executable sequences enable EvoClaw, a novel benchmark that requires agent
s to sustain system integrity and limit error accumulation, dimensions of long-t
erm software evolution largely missing from current benchmarks.
Our evaluation of 12 frontier models across 4 agent frameworks reveals a critica
l vulnerability: overall performance scores drop significantly from $>$80\% on i
solated tasks to at most 38\% in continuous settings, exposing agents' profound
struggle with long-term maintenance and error propagation.

TOM-SWE: User Mental Modeling For Software Engineering Agents
Xuhui Zhou, Valerie Chen, Zora Zhiruo Wang, Graham Neubig, Maarten Sap, Xingyao
Wang
Recent advances in coding agents have made them capable of planning, editing, ru
nning, and testing complex code bases. Despite their growing ability in coding t
asks, these systems still struggle to infer and track user intent, especially wh
en instructions are underspecified or context-dependent. To bridge this gap, we
introduce ToM-SWE, a dual-agent architecture that pairs a primary software-engin
eering (SWE) agent with a lightweight theory-of-mind (ToM) partner agent dedicat
ed to modeling the user's mental state. The ToM agent infers user goals, constra
ints, and preferences from instructions and interaction history, maintains a per
sistent memory of the user, and provides user-related suggestions to the SWE age
nt, while preserving privacy and minimizing context window load. In two software
 engineering benchmarks (ambiguous SWE-bench and stateful SWE-bench), ToM-SWE im
proves task success rates and user satisfaction. Notably, on the stateful SWE be
nchmark, a newly introduced evaluation that provides agents with a user simulato
r along with previous interaction histories, ToM-SWE achieves a substantially hi
gher task success rate of 59.7% compared to 18.1% for OpenHands, a state-of-the-
art SWE agent. Furthermore, in a three-week study with professional developers u
sing ToM-SWE in their daily work, participants found it better aligned with thei
r intent and useful 86% of the time, underscoring the value of stateful user mod
eling for practical coding agents.

Don't Reinvent the Wheel, Just Realign the Spokes: Resource-Efficient Federated
Fine-Tuning via Rank-Wise Expert Assembly
Yebo Wu, Jingguang Li, Zhijiang Guo, Li Li
Federated fine-tuning presents a promising avenue for adapting Large Language Mo
dels (LLMs) to downstream tasks while preserving data privacy. However, the proh
ibitive computational and communication overhead of LLM adaptation inhibits its
deployment on resource-constrained edge devices. In this paper, we propose Smart
Fed, a resource-efficient framework that circumvents expensive training from scr
atch by intelligently reusing knowledge embedded in existing LoRA modules. To fu
lly exploit this potential and ensure scalability, we introduce the Mixture of R
ank-Wise Experts (MoRE). MoRE decomposes LoRA modules into fine-grained rank-lev

el experts, which are selectively activated based on input semantics and resourc e budgets. Furthermore, to optimize resource utilization, we propose Elastic Exp ert Quota Allocation (EEQA), a strategy that adaptively distributes expert capac ity across parameter matrices based on their contribution to model performance. Extensive evaluations across multiple benchmarks demonstrate that SmartFed signi ficantly outperforms state-of-the-art methods in both model performance and trai ning efficiency. Our code is publicly available at https://github.com/benmagnifi co/SmartFed.

Sinkhorn Treatment Effects: A Causal Optimal Transport Measure

Medha Agarwal, Alex Luedtke

We introduce the Sinkhorn treatment effect, an entropic optimal transport measur e of divergence between counterfactual outcome distributions. Unlike classical q uantities such as the average treatment effect, it captures differences across e ntire distributions. We show that this estimand can be written as a smooth trans formation of counterfactual mean embeddings with an appropriate kernel. This cha racterization allows us to establish first-order pathwise differentiability in g eneral, and second-order pathwise differentiability under the null hypothesis of equal counterfactual distributions. Leveraging this smoothness, we construct de biased estimators and asymptotically valid tests for distributional treatment ef fects at a fixed entropic regularization parameter. Because the power of the tes t depends on this unknown parameter, we propose an aggregated test that combines evidence across a grid of regularization choices. Experiments on simulated and image data demonstrate the practical advantages of our estimator and testing pro cedure.

AdaEraser: Training-Free Object Removal via Adaptive Attention Suppression

Dingming Liu

Object removal aims to eliminate specified objects from images while plausibly i npainting the affected regions with background content. Current training-free me thods typically block attention to object regions within self-attention layers d uring the image generation process, leveraging surrounding background informatio n to restore the image. However, indiscriminate suppression of self-attention in the vacated areas can degrade generation quality, as the model must simultaneou sly reconstruct background content in these regions. To solve this conflict, we propose AdaEraser, an adaptive framework that dynamically modulates attention ba sed on the estimated presence of target object concepts. Through analysis of sel f-attention map evolution across denoising timesteps before and during removal, we develop a token-wise adaptive attention suppression strategy. This approach e nables progressive perception of object removal throughout the denoising process , with the suppression strength in self-attention layers adjusted adaptively. Ex tensive experiments demonstrate that AdaEraser achieves superior performance in object removal, outperforming even training-based methods.

Sparse Autoencoders for Interpretable Emotion Control in Text-to-Speech

Hongfei Du, Jiacheng Shi, Sidi Lu, Gang Zhou, Ashley Gao

Integrating large language models (LLMs) into text-to-speech (TTS) systems has i mproved speech expressiveness, yet interpretable emotional control remains chall enging. Existing approaches primarily rely on external conditioning or global ac tivation steering, offering limited insight into the internal representations un derlying emotional control. In this work, we analyze emotion-related variation i n the semantic hidden states of LLM-based TTS models using sparse autoencoders (SAEs) to identify sparse latent features. Our analysis shows that emotional vari ation is distributed across multiple sparse latent features, while intervening o n a small subset enables interpretable emotion control. Building on this observa tion, we introduce a feature-level intervention framework for bidirectional emot ion induction and suppression without modifying backbone parameters. We further show that distinct latent features are associated with specific acoustic attribu tes (e.g., pitch), suggesting that emotional expression arises from coordinated latent contributions rather than a single global shift. Empirically, steering th

ese sparse latent features achieves comparable or superior emotion induction and suppression performance relative to global steering and existing TTS baselines.

S-Quant: Rethinking Weight Quantization with Seed-Based Generation
Mingzi Wang, Lancheng Zou, Shuo Yin, Zhuolun He, Bei Yu
The progressive scaling of large language models (LLMs) has consistently enhanced multimodal understanding and advanced reasoning capabilities, but has substantially increased computational and hardware execution overhead.
In this paper, we present S-Quant, a novel post-method that compresses only model weights.
We partition each weight tensor into fixed-size blocks and assign a single seed to each block.
The seed drives a hardware-friendly Linear Feedback Shift Register (LFSR) generator that dynamically produces multiple basis matrices.
Each block is then reconstructed as a linear combination of these basis matrices, with block-specific coefficients, which substantially reduces the amount of stored data, increases the data-transfer efficiency between memory and compute units, and consequently speeds up memory-bound inference for large language models.
Experimental results on different LLM models ranging from 7B–70B parameters show that S-Quant attains state-of-the-art performance when weights are compressed to approximately 3-bit or 4-bit.
We also design a dedicated ASIC accelerator that achieves a 4× speed-up for memory-bound LLM inference.
****
BIT-LLM: Brain Instruction Tuned LLM with persistent Cross-Attention for fMRI-to-Text Decoding
Sunghwan Lee, Jihun Kim, Chae Lynn Kim, Ji Yun Park, Jong-Hwan Lee
Decoding fMRI into natural language is challenging because strong, pre-trained language priors can dominate autoregressive generation, obscuring whether a model truly utilizes neural evidence. We introduce BIT-LLM, which exposes fMRI-derived tokens as a persistent key–value memory through interleaved cross-attention adapters, enabling repeated neural access throughout decoding. BIT-LLM is trained with a three-stage pipeline: (i) multimodal contrastive learning to obtain semantically aligned fMRI representations, (ii) supervised fine-tuning to learn the brain-LLM interface while freezing the encoder and backbone LLM, and (iii) reward-based finetuning to optimize sequence-level caption quality directly. On the NSD subject-heldout benchmark (S1-7 train, S8 test), BIT-LLM yields substantially improved captioning quality over prior baselines under greedy decoding. In addition to standard captioning metrics, we perform several complementary evaluations to assess the robustness of brain–language grounding. Specifically, we conduct perturbation-based sanity checks by zeroing fMRI inputs or shuffling voxel values, and examine whether internal representations and generated outputs change accordingly. BIT-LLM exhibits clear sensitivity to these perturbations, indicating effective utilization of voxel values and their spatial correspondence.

RECOVER: Reliable Detection of Unauthorized Data Usage in Text-to-Image Diffusion Models via Inversion Robustness
Yanhao Wei, Xiaokang Zhao, Boheng Li, Yang Zhang, Run Wang
Text-to-Image diffusion models have achieved remarkable success in image generation and are increasingly fine-tuned for personalized use cases. However, many personalized models may incorporate unauthorized data during the fine-tuning process, raising growing concerns about potential copyright infringements. Existing methods either require intrusive modifications to the images to be protected, which not only fail to safeguard previously released images but may also degrade image quality, or rely on the availability of the pre-fine-tuned model, thereby limiting their applicability. To bridge this gap, in this paper, we propose the first non-intrusive copyright authentication framework without pre-fine-tuned model. We reveal that if a model is fine-tuned on a specific image, it learns the denoising trajectory of that image across varying noise levels, allowing it to stably reconstruct the image even under noise perturbations. Motivated by this ins

ight, we propose Reliable dEteCtion Of unauthorized data usage via inVErsion Robustness (RECOVER), an effective non-intrusive detection method without pre-fine-tuned model. Unlike existing methods that rely on external watermarks or discrepancies between the suspect and pre-fine-tuned models, RECOVER directly leverages the robustness observed during the inversion–reconstruction process of the suspect model to determine whether an image was used for fine-tuning. Extensive experiments demonstrate that RECOVER is effective across a wide range of scenarios, consistently outperforming existing methods. Our code is publicly available here.

Low-cost Full Fine-tuning: Learning What to Update for LLMs

Jin Li, Yaming Guo, Shenghao Gao, Xinlong Chen, Zuhao Xu, Ying Sun, Chao Wang, Hui Xiong

While Large language models (LLMs) have strong abilities, they generally rely on fine-tuning to supplement downstream task-specific knowledge. Due to the prohibitive memory overhead of full fine-tuning (FT), existing parameter-efficient fine-tuning techniques, e.g., LoRA and Adapters, update parameters only in low-rank or restricted subspaces. However, they fail to approximate FT---the performative fine-tuner---and risk performance degradation in tough tasks. Therefore, we naturally raise a *Low-cost Full Fine-tuning* question: Can we approach standard full fine-tuning in theory, yet with much lower costs in practice? Our key insight is that performing selective updates at each step can, theoretically, recover FT asymptotically, while being cost-effective and ignoring no parameter direction. This motivates a new general fine-tuning paradigm (called *Think-Touch*): we first predict potentials of parameter groups (*think*) and then update only the selected (*touch*) in one step. Theoretically, we show that under a very weak sufficient condition---divergence of the cumulative coverage of the expected gradient norm---any selection strategy can converge in the full-parameter space to a stationary point at which the FT admits no further first-order improvement. Besides, we further derive the general convergence rate for our paradigm and identify a post-hoc greedy strategy that is rate-optimal. Unfortunately, this strategy cannot be directly applied in practice due to its reliance on full and accurate gradient information. Thus, we propose a bandit-based method to online approximate this ideal strategy in the long run with a rigorous regret guarantee. Extensive experimental results on various tasks demonstrate the potential of our paradigm, including much lower space overheads against FT and better performance than LoRAs.

CAPTCHA Solving for Native GUI Agents: Automated Reasoning-Action Data Generation and Self-Corrective Training

Yuxi Chen, Haoyu Zhai, Chenkai Wang, Rui Yang, LINGMING ZHANG, Gang Wang, Huan Zhang

GUI agents are rapidly shifting from multi-module pipelines to end-to-end, native vision-language models (VLMs) that perceive raw screenshots and directly interact with digital devices. Despite rapid progress on general GUI tasks, CAPTCHA solving remains a major challenge. On the other hand, although specialized CAPTCHA solving pipelines exist, they cannot handle general GUI tasks.

To address this gap, we introduce ReCAP: a CAPTCHA-capable native GUI agent that solves modern, interactive CAPTCHA challenges while retaining general GUI-agent performance. We first develop a dynamic CAPTCHA system spanning seven representative CAPTCHA types, designed to stress primitive and complementary capabilities for CAPTCHA solving. Then, we develop an automated data collection and curation pipeline that generates large-scale CAPTCHA interaction trajectories paired with reasoning traces. As CAPTCHA solving often requires multi-step interaction and recovery from intermediate mistakes, we further leverage failed trajectories to construct self-correction data, training agents to reflect on errors and correct their actions online. Across synthetic and real-world test sets, ReCAP substantially improves CAPTCHA-solving success over its base agents, while maintaining strong performance on general GUI-agent benchmarks.

Ask Less, See More: Communication-Conditioned Token Pruning for Vehicle-to-Vehicle Cooperative Autonomous Driving with Multimodal Large Language Models
Shiqi Sun, Yantao Lu, Bingkun Sun, Ning Liu, Bo Jiang, Ying Zhang, Jinchao Chen, Chenglie Du
Multimodal Large Language Models (MLLMs) offer a promising paradigm for vehicle-to-vehicle (V2V) cooperative autonomous driving, enabling language-based decision-making in safety-critical occluded scenarios. However, existing V2V–MLLM frameworks rely on dense token-level sharing and fusion, incurring high communication and inference costs. Moreover, conventional V2V perception methods are limited to feature-sharing paradigms without language reasoning, and existing token pruning strategies fail to consider LiDAR-specific spatial structure and multi-agent fusion. To address these limitations, we propose V2V Communication-Conditioned MLLM Framework (V2V-CCM), a dual-stage cooperative communication framework that broadcasts request messages to all agents and uses them to identify redundant visual tokens. Specifically, Question Semantic Message (QSM) encodes global question intent for question-relevant token selection, while Spatial Coverage Message (SCM) summarizes LiDAR features to identify spatially redundant tokens already observed by other agents. Integrated into dual-stage frameworks, V2V-CCM substantially reduces communication and inference costs while preserving question-relevant tokens and removing spatial redundancy. Extensive experiments on V2V-QA and V2V-GoT-QA demonstrate that V2V-CCM consistently outperforms existing pruning methods and achieves state-of-the-art performance.

A General Framework for Dynamic Consistent Submodular Maximization
Paul Duetting, Federico Fusco, Silvio Lattanzi, Ashkan Norouzi-Fard, Ola Svensson, Morteza Zadimoghaddam
Consistency is an important property in dynamic submodular maximization and entails maintaining a near-optimal solution at all times, making only a small number of adjustments to the solution in each step. Prior work has explored this question for the insertion-only case, where the algorithm faces a stream of n insertions, and has established lower and upper bounds for the cardinality-constrained version of the problem. We consider this question in the fully dynamic setting, where the stream of operations may contain both insertions and deletions.

We develop a general framework for designing algorithms for this setting, and instantiate it to obtain the first constant-factor approximations with sublinear consistency. For cardinality constraints, we propose a $\tfrac 12 - O(\varepsilon)$ approximation that is $O\left(\tfrac{1}{\varepsilon^2}\right)$ consistent. For rank-k matroid constraints, we construct a $\tfrac 14 - O(\varepsilon)$ approximation to the dynamic optimum that is $O\left(\tfrac{\log k}{\varepsilon^2}\right)$ consistent.

ATLAS: Learning to Optimally Memorize the Context at Test Time
Ali Behrouz, Zeman Li, Praneeth Kacham, Majid Daliri, Yuan Deng, Peilin Zhong, Meisam Razaviyayn, Vahab Mirrokni
Transformers have been established as the most popular backbones in sequence modeling, mainly due to their effectiveness in in-context retrieval tasks and the ability to learn at scale. Their quadratic memory and time complexity, however, bound their applicability in longer sequences and so has motivated researchers to explore effective alternative architectures such as modern recurrent neural networks (a.k.a long-term recurrent memory module). Despite their recent success in diverse downstream tasks, they struggle in tasks that requires long context understanding and extrapolation to longer sequences. We observe that these shortcomings come from three disjoint aspects in their design: (1) limited memory capacity that is bounded by the architecture of memory and feature mapping of the input; (2) online nature of update, i.e., optimizing the memory only with respect to the last input; and (3) less expressive management of their fixed-size memory. To enhance all these three aspects, we present Atlas, a long-term memory module with high capacity that learns to memorize the context by optimizing the memory based on the current and past tokens, overcoming the online nature of long-term

memory models. Our experimental results on language modeling, common-sense reasoning, recall-intensive, and long-context understanding tasks support the effectiveness of Atlas compared to other modern recurrent neural networks.

Plain Transformers are Surprisingly Powerful Link Predictors
Quang Truong, Yu Song, Donald Loveland, Mingxuan Ju, Tong Zhao, Neil Shah, Jiliang Tang
Link prediction is a core challenge in graph machine learning, demanding models that capture rich and complex topological dependencies. While Graph Neural Networks (GNNs) are the standard solution, state-of-the-art pipelines often rely on explicit structural heuristics or memory-intensive node embeddings—approaches that struggle to generalize or scale to massive graphs. Emerging Graph Transformers (GTs) offer a potential alternative but often incur significant overhead due to complex structural encodings, hindering their applications to large-scale link prediction. We challenge these sophisticated paradigms with PENCIL, an encoder-only plain Transformer that replaces hand-crafted priors with attention over sampled local subgraphs, retaining the scalability and hardware efficiency of standard Transformers. Through experimental and theoretical analysis, we show that PENCIL extracts richer structural signals than GNNs, implicitly generalizing a broad class of heuristics and subgraph-based expressivity. Empirically, PENCIL outperforms heuristic-informed GNNs and is far more parameter-efficient than ID-embedding–based alternatives, while remaining competitive across diverse benchmarks—even without node features. Our results challenge the prevailing reliance on complex engineering techniques, demonstrating that simple design choices are potentially sufficient to achieve the same capabilities. Our code is publicly available at https://github.com/quang-truong/pencil.

Benchmarking Physics-Informed Time-Series Models for Operational Global Station Weather Forecasting
Tao Han, Zhibin Wen, Zhenghao Chen, Dazhao Du, Song Guo, LEI BAI
The development of Time-Series Forecasting (TSF) models is often constrained by the lack of comprehensive datasets, especially in Global Station Weather Forecasting (GSWF), where existing datasets are small, temporally short, and spatially sparse. To address this, we introduce WEATHER-5K, a large-scale observational weather dataset that better reflects real-world conditions and supports improved model training and evaluation. While recent TSF methods perform well on benchmarks, they still lag behind operational Numerical Weather Prediction (NWP) systems in capturing complex weather dynamics and extreme events. We propose PhysicsFormer, a physics-informed forecasting model that combines a dynamic core with a Transformer residual to predict future weather states. Physical consistency is enforced via pressure–wind alignment and energy-aware smoothness losses, ensuring plausible dynamics while capturing complex temporal patterns. We benchmark PhysicsFormer and other TSF models against operational systems across several weather variables, extreme event prediction, and model complexity, providing a comprehensive assessment of the gap between academic TSF models and operational forecasting. The dataset and benchmark implementation are available at: https://github.com/taohan10200/WEATHER-5K.

Geometry-Aware Decoding with Wasserstein-Regularized Truncation and Mass Penalties for Large Language Models
Arash Gholami Davoodi, Navid Rezazadeh, Seyed Pouyan Mousavi Davoudi, Pouya Pezeshkpour
Large language models (LLMs) must balance diversity and creativity against logical coherence in open-ended generation.
Existing truncation-based samplers are effective but largely heuristic, relying mainly on probability mass and entropy while ignoring semantic geometry of the token space.
We present Top-W, a geometry-aware truncation rule that uses Wasserstein distance—defined over token-embedding geometry—to keep the cropped distribution close to the original, while explicitly balancing retained probability mass against t

he entropy of the kept set.
Our theory yields a simple closed-form structure for the fixed-potential subset update: depending on the mass–entropy trade-off, the optimal crop either collapses to a single token or takes the form of a one-dimensional prefix that can be found efficiently with a linear scan.
We implement Top-W using efficient geometry-based potentials (nearest-set or k-NN) and pair it with an alternating decoding routine that keeps the standard truncation-and-sampling interface unchanged.
Extensive experiments on four benchmarks (GSM8K, GPQA, AlpacaEval, and MT-Bench) across three instruction-tuned models show that Top-W consistently outperforms prior state-of-the-art decoding approaches achieving up to 33.7 percentage improvement.
Moreover, we find that Top-W not only improves accuracy-focused performance, but also boosts creativity under judge-based open-ended evaluation.

FUSE: Full■spectrum Unlearnable Examples via Spectral Equalization
Jiale Cai, Gezheng Xu, Zhihao Li, Ruiyi Fang, Ruizhi Pu, Di Wu, Qicheng Lao, Charles Ling, Boyu Wang
Unlearnable examples (UEs) protect training data by injecting imperceptible perturbations so that models fail to extract exploitable representations. In this paper, we reveal that existing UEs exhibit a critical failure once low-pass filtering is applied, indicating that the effective perturbation signals for unlearnability concentrate predominantly in high frequencies. Hence, we argue that reliable UEs should remain effective across the full spectrum. To this end, we propose **F**ull-spectrum **U**nlearnable Examples via **S**pectral **E**qualization (**FUSE**), which aims to generate spectrum-agnostic perturbations by equalizing the contributions from different bands and enforcing cross-band consistency. Specifically, FUSE adopts a Random Spectral Masking (RSM) strategy during generator training, which randomly removes a contiguous frequency band, forcing the remaining bands to maintain unlearnability. In addition, FUSE further integrates Cross-Band Guidance (CBG), which enforces mutual consistency between high- and low-frequency components, thereby further enhancing low-frequency unlearnability and regulating high-frequency perturbations to preserve the semantic fidelity of images. Extensive experiments across multiple datasets, architectures, and spectral filtering demonstrate the strong protection achieved by FUSE.

Near-Optimal Dynamic Matching via Coarsening with Application to Heart Transplantation
Itai Zilberstein, Ioannis Anagnostides, Zachary W. Sollie, Arman Kilic, Tuomas Sandholm
Online matching has been a mainstay in domains such as Internet advertising and organ allocation, but practical algorithms often lack strong theoretical guarantees. We take an important step toward addressing this by developing new online matching algorithms based on a coarsening approach. Although coarsening typically implies a loss of granularity, we show that, to the contrary, aggregating offline nodes into capacitated clusters can yield near-optimal theoretical guarantees. We apply our methodology to heart transplant allocation to develop theoretically grounded policies based on structural properties of historical data. Furthermore, in simulations based on real data, our policy closely matches the performance of the omniscient benchmark, achieving competitive ratio 0.91, drastically higher than the US status quo policy's 0.51. Our work bridges the gap between data-driven heuristics and pessimistic theoretical lower bounds.

Quantum latent distributions in deep generative models
Omar Bacarreza, Thorin Farnsworth, Alexander Makarovskiy, Hugo Wallner, Tessa Hicks, Santiago Sempere-Llagostera, John J Price, Robert J. A. Francis-Jones, William R. Clements
Many successful families of generative models leverage a low-dimensional latent distribution that is mapped to a data distribution. Though simple latent distributions are often used, the choice of distribution has a strong impact on model p

erformance. Recent experiments have suggested that the probability distributions produced by quantum processors, which are typically highly correlated and classically intractable, can lead to improved performance on some datasets. However, when and why latent distributions produced by quantum processors can improve performance, and whether these improvements are connected to quantum properties of these distributions, are open questions that we investigate in this work. We show in theory that, under certain conditions, these "quantum latent distributions" enable generative models to produce data distributions that classical latent distributions cannot efficiently produce. We provide intuition as to the underlying mechanisms that could explain a performance advantage on real datasets. Based on this, we perform extensive benchmarking on a synthetic quantum dataset and the QM9 molecular dataset, using both simulated and real photonic quantum processors. We find that the statistics arising from quantum interference lead to improved generative performance compared to classical baselines, suggesting that quantum processors can play a role in expanding the capabilities of deep generative models.

Spike Camera Autofocus via Frequency-Domain Spectral-Centroid Migration

Xijie Xiang, Lin Zhu, Yonghong Tian

Autofocus for spike cameras is challenging because their sparse binary measurements do not provide reliable instantaneous gradients, and noise or illumination drift often breaks the unimodal assumptions behind conventional focus measures. We show that during a focus sweep, the stable sensor-observable cue is a persistent migration of spectral energy in the frequency domain: energy shifts outward toward higher frequencies when approaching focus and recedes under renewed defocus. Building on this observation, we propose CEN (Centroid-based Energy Navigation), a frequency-domain autofocus method that measures spectral migration via a bounded spectral centroid computed on accumulated spike blocks, without image reconstruction or explicit edge extraction. To handle multi-peak and irregular responses in real scenes, CEN further performs structure-consistent response identification, selecting the frequency bound whose curve exhibits a clear, localized, interior extremum, followed by robust peak localization using a weighted near-maximum centroid.

Experiments on spike-camera dataset demonstrate that CEN achieves the best overall accuracy and response discriminability across diverse scenes, motion types, and illumination variation patterns.

Beyond First-order Asymptotics in Sequential Mean Testing

VIKAS DEEP, Shubhada Agrawal

We revisit the problem of sequentially testing the mean of bounded distributions in a level-α power-one framework. We study a $\mathrm{KL_{inf}}$-based sequential test that is known to attain the information-theoretic lower bound on the expected stopping time with exact constants as $\alpha \to 0$. Going beyond first-order asymptotics, we establish a central limit theorem (CLT) for the stopping time of this test. Our analysis proceeds in two steps. First, we prove a novel CLT for the $\mathrm{KL_{inf}}$ statistic itself, characterizing its fluctuations around its deterministic limit. We then leverage this result to show that the stopping time, centered appropriately and scaled by $\sqrt{\log(1/\alpha)}$, converges in distribution to a Gaussian limit with an explicit variance. This yields a second-order characterization of an asymptotically optimal sequential test for bounded distributions. Finally, we present numerical experiments that corroborate our theoretical findings.

Dimension-free convergence of diffusion models for approximate Gaussian mixtures

Gen Li, Changxiao Cai, Yuting Wei

Diffusion models are distinguished by their exceptional generative performance, particularly in producing high-quality samples through iterative denoising. While current theory suggests that the number of denoising steps required for accurate sample generation should scale linearly with data dimension, this does not reflect the practical efficiency of widely used algorithms like Denoising Diffusio

n Probabilistic Models (DDPMs). This paper investigates the effectiveness of dif fusion models in sampling complex high-dimensional distributions that can be wel l-approximated by Gaussian Mixture Models (GMMs). For these distributions, our m ain result shows that DDPM takes at most $\widetilde{O}(1/\varepsilon)$ iteratio ns to attain an ε-accurate distribution in total variation (TV) dist ance, independent of both the ambient dimension d and the number of components K, up to logarithmic factors. Furthermore, this result remains robust to scor e estimation errors. These findings highlight the remarkable effectiveness of di ffusion models in high-dimensional settings given the universal approximation ca pability of GMMs, and provide theoretical insights into their practical success.

On the Role of Computation in Reinforcement Learning

Raj Ghugare, Micha■ Bortkiewicz, Alicja Ziarko, Benjamin Eysenbach

How does the amount of compute available to a reinforcement learning (RL) policy affect its learning? Can policies using a fixed amount of parameters, still ben efit from additional compute? The standard RL framework does not provide a langu age to answer these questions formally. Empirically, deep RL policies are often parameterized as neural networks with static architectures, conflating the amoun t of compute and the number of parameters. In this paper, we formalize compute b ounded policies and prove that policies which use more compute can solve problem s and generalize to longer-horizon tasks that are outside the scope of policies with less compute. Building on prior work in algorithmic learning and model-free planning, we propose a minimal architecture that can use a variable amount of c ompute. Our experiments complement our theory. On a set 31 different tasks spann ing online and offline RL, we show that (1) this architecture achieves stronge r performance simply by using more compute, and (2) stronger generalization on longer-horizon test tasks compared to standard feedforward networks or deep res idual network using upto 5 times more parameters.

Adaptive Token Refinement in Long-Tailed Large Vision-Language Models Fine-Tunin g

Wenjun Miao, Mingda Li, Yanchao Hao, Zheng Wei

While large vision-language models (LVLMs) have shown remarkable adaptability to downstream applications, their fine-tuning process remains susceptible to bias under long-tailed data.

Compared to zero-shot scenarios, fine-tuning LVLMs on imbalanced datasets often yields limited performance improvements on tail data.

This is because LVLMs tend to rapidly overfit the head data at an early fine-tun ing stage, thereby impairing the learning of the tail data while simultaneously failing to exploit their quantitative advantage.

Furthermore, in many downstream LVLM scenarios, quantified long-tailed prior kno wledge of data distribution is often unavailable, significantly limiting the app licability of traditional long-tailed techniques that rely heavily on such infor mation.

To address these issues, we propose the Adaptive Token Refinement (ATR), a novel framework that adaptively refines the learning process of LVLMs under long-tail ed data.

Specifically, ATR consists of two token-level operations applied to output and i nput tokens, respectively: 1) a bounded adaptive loss that dynamically filters a nd reweights output tokens to mitigate overfitting on head data,

and 2) a visual token mask strategy that augments the probability paths of input tokens to enhance long-tailed performance.

Extensive experiments demonstrate that ATR consistently enhance both performance and generalization for long-tailed LVLMs fine-tuning.

Posterior Behavioral Cloning: Pretraining BC Policies for Efficient RL Finetunin g

Andrew Wagenmaker, Perry Dong, Raymond Tsao, Chelsea Finn, Sergey Levine

Standard practice across domains from robotics to language is to first pretrain a policy on a large-scale demonstration dataset, and then finetune this policy,

typically with reinforcement learning (RL), in order to improve performance on deployment domains. This finetuning step has proved critical in achieving human or super-human performance, yet while much attention has been given to developing more effective finetuning algorithms, little attention has been given to ensuring the pretrained policy is an effective initialization for RL finetuning. In this work we seek to understand how the pretrained policy affects finetuning performance, and how to pretrain policies in order to ensure they are effective initializations for finetuning. We first show theoretically that standard behavioral cloning (BC) can fail to ensure coverage over the demonstrator's actions, a minimal condition necessary for effective RL finetuning. We then show that if, instead of exactly fitting the observed demonstrations, we train a policy to model the posterior distribution of the demonstrator's behavior given the demonstration dataset, we do obtain a policy that ensures coverage over the demonstrator's actions, enabling more effective finetuning. Furthermore, this policy achieves this while ensuring pretrained performance is no worse than that of the BC policy. We then show this approach is practically implementable with modern generative models and leads to significantly improved RL finetuning performance on both realistic robotic control benchmarks and real-world robotic manipulation tasks, as compared to standard behavioral cloning.

Code2Video: A Code-centric Paradigm for Educational Video Creation

Yanzhe Chen, Kevin Qinghong Lin, Mike Zheng Shou

While recent generative models can synthesize videos in pixel space, they often fail to produce educational videos with precise structures, domain knowledge, and coherent transitions. We argue that this setting is better served by operating in a renderable environment that is explicitly controlled by code. We propose **Code2Video**, a code-centric agent framework that generates educational videos by writing executable Python programs. Code2Video includes three agents: a *Planner* that converts lecture content into a temporal storyboard, a *Coder* that turns the storyboard into runnable code with scope-guided auto-fix, and a *Critic* that refines layout using a VLM guided by *visual anchor prompting*, *i.e.*, mappings from target visual outcomes to code edits. For evaluation, we build **MMMC**, a benchmark of professionally produced, discipline-specific educational videos. We assess Code2Video using aesthetic scores (VLM-as-a-Judge), code efficiency, and **TeachQuiz**, an end-to-end metric that measures how well an *unlearned* VLM can recover knowledge after watching generated videos. Code2Video improves performance by 40% over direct code generation and produces videos comparable to human-crafted tutorials. The code and datasets are available at https://github.com/showlab/Code2Video.

Zero-Shot Off-Policy Learning

Arip Asadulaev, Maksim Bobrin, Salem Lahlou, Dmitry V. Dylov, Fakhri Karray, Martin Taká■

Off-policy learning methods seek to derive an optimal policy directly from a fixed dataset of prior interactions. This objective presents significant challenges, primarily due to the inherent distributional shift and value function overestimation bias.

These issues become even more noticeable in zero-shot reinforcement learning, where an agent trained on reward-free data must adapt to new tasks at test time without additional training.

In this work, we address the off-policy problem in a zero-shot setting by discovering a theoretical connection of successor measures to stationary density ratios.

Using this insight, our algorithm can infer optimal importance sampling ratios, effectively performing a stationary distribution correction with an optimal policy for any task on the fly.

We benchmark our method in motion tracking tasks on SMPL Humanoid, continuous control on ExoRL, and for the long-horizon OGBench tasks.

Our technique seamlessly integrates into forward-backward representation frameworks and enables fast-adaptation to new tasks in a training-free regime.

More broadly, this work bridges off-policy learning and zero-shot adaptation, of
fering benefits to both research areas.

WorldMirror: Universal 3D World Reconstruction with Any-Prior Prompting
Yifan Liu, Zhiyuan Min, Zhenwei Wang, Junta Wu, Tengfei Wang, Yixuan Yuan, Yawei
 Luo, Chunchao Guo
We present WorldMirror, a unified feed-forward model for comprehensive 3D geomet
ric prediction tasks.
Unlike existing methods constrained to image-only inputs or customized for a spe
cific task, our framework flexibly integrates diverse geometric priors, includin
g camera poses, intrinsics, and depth maps, while simultaneously generating mult
iple 3D representations: dense point clouds, multi-view depth maps, camera param
eters, surface normals, and 3D Gaussians. Remarkably, prior injection yields uni
versal gains across all tasks, suggesting that input flexibility and multi-task
prediction are mutually reinforcing. WorldMirror achieves state-of-the-art perfo
rmance across diverse benchmarks from camera, point map, depth, and surface norm
al estimation to novel view synthesis, while maintaining the efficiency of feed-
forward inference. Code and model weights are publicly available at https://gith
ub.com/Tencent-Hunyuan/HunyuanWorld-Mirror.

MARS-SQL: A Multi-Agent Reinforcement Learning Framework For Text-To-SQL
Haolin Yang, Jipeng Zhang, Zhitao He, Alexander Zhou, Yi R. Fung
Large Language Models (LLMs) often struggle with the precise logic and schema al
ignment required for complex Text-to-SQL tasks. While current methods rely heavi
ly on static prompting, they lack the ability to dynamically adapt and self-corr
ect through environmental interaction. To bridge this gap, we propose **MARS-SQL
**, a trainable multi-agent framework for Text-to-SQL. Rather than introducing a
 new standalone SQL primitive, **MARS-SQL** makes an agentic workflow trainable
by decomposing the problem into three specialized roles: schema grounding, query
 generation, and solution validation. Central to our approach is a generation ag
ent trained via a multi-turn RL policy within a ReAct-style loop. The agent lear
ns to iteratively reason, execute intermediate SQL actions on a live database, a
nd refine its strategy based on execution feedback. To improve robustness, we fu
rther introduce a validation mechanism that treats solution selection as a gener
ative modeling task, identifying the optimal interaction trajectory through next
-token prediction probabilities. Empirical evaluations demonstrate the effective
ness of coupling interactive learning with trajectory ranking. **MARS-SQL** achi
eves state-of-the-art performance, recording an execution accuracy of 77.84\% on
 the BIRD development dataset and 89.75\% on the Spider test dataset, while also
 transferring strongly to out-of-domain benchmarks.
Code is available at https://github.com/YangHaolin0526/MARS-SQL.

PepCompass: Navigating Peptide Embedding Spaces Using Riemannian Geometry
Marcin Mo■ejko, Adam Bielecki, Jurand Pr■dzy■ski, Hyun-Su Lee, Antoni Janowski,
Michal Kmicikiewicz, Paulina Szymczak, Karol Jurasz, Marcin Traskowski, Micha■ K
ucharczyk, Marcelo Der Torossian Torres, Cesar de la Fuente-Nunez, Ewa Szczurek
Antimicrobial peptide discovery is challenged by the astronomical size of peptid
e space and the relative scarcity of active peptides.
While generative models provide latent maps of this space, they typically ignore
 decoder-induced geometry and rely on flat Euclidean metrics, making exploration
 distorted and inefficient. Existing manifold-based approaches assume fixed int
rinsic dimensionality, which fails for real peptide data. We introduce **PepComp
ass**, a geometry-aware framework based on a **Union of κ-Stable Riemann
ian Manifolds** that captures local decoder geometry while maintaining computati
onal stability. PepCompass performs global interpolation via **Potential-minimiz
ing Geodesic Search (PoGS)** to bias discovery toward promising seeds and enable
s local exploration through **Second-Order Riemannian Brownian Efficient Samplin
g** and **Mutation Enumeration in Tangent Space**, which together form **Local E
numeration Bayesian Optimization (LE-BO)**. PepCompass achieves a 100% *in-vitro
* validation rate: PoGS identifies four novel seeds and LE-BO optimizes them in

to 25 highly active, broad-spectrum peptides, demonstrating that geometry-informed exploration is a powerful paradigm for antimicrobial peptide design.

Conformal C2ST: Turning weak classifiers into strong two-sample tests
Vansh Bansal, Tianyu Chen, James G. Scott
The two-sample testing problem, a fundamental task in statistics and machine learning, seeks to determine whether two sets of samples, drawn from underlying distributions p and q, are in fact identically distributed (i.e.~whether $p=q$). A popular and intuitive approach is the classifier two-sample test (C2ST), where a classifier is trained to distinguish between samples from p and q. Yet despite simplicity of the C2ST, its reliability hinges on access to a near-Bayes-optimal classifier, a requirement that is rarely met and difficult to verify. This raises a major open question: can a weak classifier still be useful for two-sample testing? We show that the answer is a definitive yes. Building on the work of Hu & Lei (2024), we analyze two conformal variants of the C2ST that convert the scores from any trained classifier---even if weak, biased, or overfit---into exact, finite-sample p-values. We establish two key theoretical properties of the conformal C2ST: (i) finite-sample Type-I error control, and (ii) non-trivial power that degrades gently in tandem with the error of the trained classifier. The upshot is that even poorly performing classifiers can yield powerful and reliable two-sample tests. This general framework finds a powerful application in Bayesian inference, particularly for validating Neural Posterior Estimation (NPE) models, where the task of comparing a learned posterior approximation $q(\theta \mid y)$ to the true posterior $p(\theta \mid y)$ can be framed as a two-sample test. Empirically, the Conformal C2ST outperforms classical discriminative tests across a wide range of benchmarks for this task. Our results establish the conformal C2ST as a practical, theoretically grounded diagnostic tool.
****
Learning Latent Action World Models in the Wild
Quentin Garrido, Tushar Nagarajan, Basile Terver, Nicolas Ballas, Yann LeCun, Michael Rabbat
Agents that can reason and plan in the real world must be able to predict the consequences of their actions. World models possess this capability but require action annotations that can be complex to obtain at scale. Latent action models address this issue by learning an action space from videos alone. Our work studies the training of latent action world models on in-the-wild videos, expanding the scope of existing works that focus on simple robotics simulations, video games, or manipulation data. While diverse videos enable modeling richer actions, they introduce challenges of environmental noise and lack of a common embodiment across videos. To address these, we carefully study the design and evaluation of latent actions. We find that constrained continuous latent actions are better suited for complex in-the-wild videos, compared to vector quantization. For example, actions specific to in-the-wild videos such as humans entering the room, can be modeled and then transferred across videos. However, in the absence of a common embodiment, learned latent actions are localized in space, relative to the camera. Nonetheless, we are able to train a controller that maps known actions to latent ones, allowing us to use latent actions as a universal interface to solve planning tasks on par with action-conditioned baselines.
****
Efficient privacy loss accounting for subsampling and random allocation
Vitaly Feldman, Moshe Shenfeld
We consider the privacy amplification properties of a sampling scheme in which a user’s data is used in k steps chosen randomly and uniformly from a sequence (or set) of t steps. This sampling scheme has been recently applied in the context of differentially private optimization [Chua et al., 2024a, Choquette-Choo et al., 2025] and communication-efficient high-dimensional private aggregation [Asi et al., 2025], where it was shown to have utility advantages over the standard Poisson sampling. Theoretical analyses of this sampling scheme [Feldman and Shenfeld, 2025, Dong et al., 2025] lead to bounds that are close to those of Poisson sampling, yet still have two significant shortcomings. First, in many practi

cal settings, the resulting privacy parameters are not tight due to the approximation steps in the analysis. Second, the computed parameters are either the hockey stick or Rényi divergence, both of which introduce overheads when used in privacy loss accounting. In this work, we demonstrate that the privacy loss distribution (PLD) of random allocation applied to any differentially private algorithm can be computed efficiently. When applied to the Gaussian mechanism, our results demonstrate that the privacy-utility trade-off for random allocation is at least as good as that of Poisson subsampling. In particular, random allocation is better suited for training via DP-SGD. To support these computations, our work develops new tools for general privacy loss accounting based on a notion of PLD realization. This notion allows us to extend accurate privacy loss accounting to subsampling which previously required manual noise-mechanism-specific analysis.

Learning Dynamic Stability Landscapes in Synchronization Networks
Christian Nauck, Junyou Zhu, Michael Lindner, Frank Hellmann
The robustness of synchronization is typically characterized by scalar, per-node stability indices whose dependence on topology is studied via network science or graph neural networks (GNNs). We propose a novel upstream task, stability landscapes, which provide deeper insights into synchronization behavior and from which many such scalar indices can be derived. Crucially, we pioneer a graph-to-image prediction paradigm: learning image-like landscapes as per-node targets directly from graph topology, a formulation we are not aware of having been established elsewhere in the literature. To support this task, we release two datasets of 10,000 graphs each at 20 and 100 nodes with per-node landscape labels, based on a conceptual oscillator model, capturing power grid synchronization behavior. A GNN encodes topology and a CNN decoder renders per-node images, learned end-to-end with good in-distribution accuracy, generalizing across graph sizes and to realistic power grid topologies. This demonstrates that stability landscapes, while beyond the reach of conventional network science, are learnable from topology and open new avenues for moving beyond scalar stability indices in biology, neuroscience, and power grids.

rePIRL: Learn PRM with Inverse RL for LLM Reasoning
Xian Wu, Kaijie Zhu, Ying Zhang, Lun Wang, Wenbo Guo
Process rewards have been widely used in deep reinforcement learning to improve training efficiency, reduce variance, and prevent reward hacking. In LLM reasoning, existing works also explore various solutions for learning effective process reward models (PRM) with or without the help of an expert policy. However, existing methods either rely on strong assumptions about the expert policies (e.g., requiring their reward functions) or suffer intrinsic limitations (e.g., entropy collapse), resulting in weak PRMs or limited generalizability. In this paper, we introduce rePIRL, an inverse RL-inspired framework that learns effective PRMs with minimal assumptions about expert policies. Specifically, we design a dual learning process that updates the policy and the PRM interchangeably. Our learning algorithm has customized techniques to address the challenges of scaling traditional inverse RL to LLMs. We theoretically show that our proposed learning framework can unify both online and offline PRM learning methods, justifying that rePIRL can learn PRMs with minimal assumptions. Empirical evaluations on standardized math and coding reasoning datasets demonstrate the effectiveness of rePIRL over existing methods. We further show the application of our trained PRM in test-time training, test-time scaling, and providing an early signal for training hard problems. Finally, we validate our training recipe and key design choices via a detailed ablation study.

DRFusion: Drift-Resilient Temporally Consistent Infrared–Visible Video Fusion
Xingyuan Li, HaoYuan Xu, Shulin Li, Xiang Chen, Zhiying Jiang, Jinyuan Liu
Infrared and visible video fusion is essential for achieving comprehensive perception in dynamic scenes. However, maintaining temporal consistency remains a formidable challenge. Conventional methods relying on optical flow often suffer from geometric rigidity and ghosting artifacts. Moreover, standard diffusion-based

fusion models typically operate in a frame-by-frame manner; when extended to autoregressive settings, they lack intrinsic temporal constraints and are prone to severe error accumulation and drifting, where minor artifacts amplify over time. To address these limitations, we propose a drift-resilient video fusion method that reformulates the task as history-conditioned motion generation. We introduce Stabilized History Guidance and Soft Temporal Anchoring to reframe temporal consistency as spectral filtering, implicitly aggregating motion dynamics without rigid alignment. Furthermore, our Decoupled Structure-Motion Adaptation strategy bridges pre-trained priors and structural constraints via two-stage training and latent refinement. Extensive experiments demonstrate that our method achieves state-of-the-art performance in both fusion quality and temporal stability.
****

Learning Permutation from Structure Without Supervision
Ran Eisenberg, Ofir Lindenbaum
Many learning problems require uncovering a hidden ordering that reveals structure in unordered data, such as monotonicity in sorting or spatial continuity in jigsaw reconstruction. In these settings, permutations can be learned as latent operators by optimizing objectives defined directly on the reordered output, often without access to ground-truth orderings. Differentiable relaxations such as Gumbel–Sinkhorn make this approach practical by approximating permutation matrices with doubly stochastic matrices. However, learning from structure without supervision induces a non-uniform uncertainty: some assignments become confident early, while others remain ambiguous. Existing methods control this process using a single global temperature, forcing all assignments to sharpen or diffuse simultaneously and leading to instability at scale. We introduce an entropy-adaptive formulation of Gumbel–Sinkhorn that locally modulates temperature based on assignment uncertainty. This allows confident assignments to discretize early while preserving exploration where uncertainty remains. Across sorting and jigsaw reconstruction tasks and in routing-style settings, adaptive entropy control improves training stability and final permutation quality relative to fixed-temperature baselines, particularly as problem size and assignment ambiguity increase.

ScreenParse: Moving Beyond Sparse Grounding with Complete Screen Parsing Supervision
A. Said Gurbuz, Sunghwan Hong, Ahmed Nassar, Marc Pollefeys, Peter W. J. Staar
Modern computer-use agents (CUA) must perceive a screen as a structured state, what elements are visible, where they are, and what text they contain, before they can reliably ground instructions and act. Yet, most available grounding datasets provide sparse supervision, with *insufficient* and *low-diversity* labels that annotate only a small subset of task-relevant elements per screen, which limits both coverage and generalization; moreover, practical deployment requires efficiency to enable low-latency, on-device use. We introduce **ScreenParse**, a large-scale dataset for *complete* screen parsing, with dense annotations of all visible UI elements (boxes, 55-class types, and text) across 771K web screenshots (21M elements). ScreenParse is generated by **Webshot**, an automated, scalable pipeline that renders diverse urls, extracts annotations and applies VLM-based relabeling and quality filtering. Using ScreenParse, we train **ScreenVLM**, a compact, 316M-parameter vision language model (VLM) that decodes a compact ScreenTag markup representation with a structure-aware loss that upweights structure-critical tokens. ScreenVLM substantially outperforms much larger foundation VLMs on dense parsing (e.g., 0.592 vs. 0.294 PageIoU on ScreenParse) and shows strong transfer to public benchmarks. Moreover, finetuning foundation VLMs on ScreenParse consistently improves their grounding performance, suggesting that dense screen supervision provides transferable structural priors for UI understanding. The dataset, model and code will be made publicly available.

FlatLand: Personalized Graph Federated Learning via Tailored Lorentz Space

Jiahong Liu, Ram Samarth B B, Xinyu Fu, Menglin Yang, Weixi Zhang, Rex Ying, Irw in King

Personalization has become a pivotal field of study in contemporary intelligent systems.

Federated learning enables privacy-preserving collaborative training, but highly heterogeneous client data remain challenging, especially in graph federated lea rning where clients possess structurally diverse graphs. Existing personalized f ederated learning (PFL) methods ignore the intrinsic geometric properties of div erse graph structures. We propose FlatLand, a novel personalized Federated learn ing method that embeds different clients' data in tailored Lorentz space of hype rbolic geometry. Our key insight is that hyperbolic geometry naturally accommoda tes the intrinsic negative curvature prevalent in real-world graphs, while the t ime-like dimension in Lorentz space provides a principled way to encode client-s pecific heterogeneity. We develop a parameter decoupling strategy that separates heterogeneous information (captured in time-like parameters) from common knowle dge (preserved in space-like parameters), enabling direct aggregation without re quiring client similarity estimation and extra calculation modules. Empirical re sults on diverse federated graph learning tasks demonstrate that FlatLand achiev es superior performance, particularly in low-dimensional settings. Code is avail able in our GitHub repository.

Predicting Large Model Test Losses with a Noisy Quadratic System

Chuning Li, Chris J. Maddison

We introduce a predictive model that estimates the pre-training loss of large mo dels from model size (N), batch size (B) and number of weight updates (K). This is the first loss prediction model that can handle changing batch size. Th e model outperforms Chinchilla's loss model, a model of the test loss using the batch size and number of tokens, in terms of projecting the loss at extrapolated compute budgets (up to 1000 folds). A natural use of the model is to find optim al N,B,K configurations under explicit and compound resource constraints like time, memory and compute. In our experiments, the model-selected configurations are close to ground-truth optimal. Our work advocates for loss prediction as a b etter alternative to heuristic-based laws, which are growing in complexity. The implementation is available on \href{https://github.com/chuningxdy/Noisy-Quadrat ic-System}{GitHub}.

RLIE: Rule Generation with Logistic Regression, Iterative Refinement, and Evalua tion for Large Language Models

Yang Yang, Hua XU, Zhangyi Hu, Yutao Yue

Large Language Models (LLMs) can propose natural-language rules, circumventing t he reliance on a predefined predicate space in traditional rule learning. Howeve r, existing LLM-based methods often neglect the global interactions among rules, and the potential of using fine-grained rule importance scores to calibrate neu ro-symbolic reasoning remains underexplored. To address this gap, we introduce R

LIE, a framework that integrates LLMs with probabilistic modeling to learn weighted rule sets in four stages: (1) Rule generation: proposing and filtering candidate rules via LLMs; (2) Logistic regression: learning sparse, calibrated weights for global rule selection; (3) Iterative refinement: revising the rule set with error-driven hard examples; and (4) Evaluation: validating the learned system via comparative inference paradigms. Across multiple real-world datasets and LLM backbones, our learned weighted rules achieve superior stability and accuracy, whereas rule-injection prompting yields mixed results and often degrades performance. These results suggest LLMs excel at semantic rule discovery but are less reliable at controlled probabilistic aggregation. Our findings highlight both the promise and the limits of LLMs for inductive reasoning, motivating a principled integration with classic probabilistic rule combination for reliable neuro-symbolic reasoning.

SEMA: a Scalable and Efficient Mamba like Attention via Token Localization and Averaging

Nhat Thanh Tran, Fanghui Xue, shuai zhang, Jiancheng Lyu, Yunling Zheng, Yingyong Qi, Jack Xin

Attention is the critical component of a transformer. Yet the quadratic computational complexity of vanilla full attention in the input size and the inability of its linear attention variant to focus have been challenges for computer vision tasks. We provide a mathematical definition of generalized attention and formulate both vanilla softmax attention and linear attention within the general framework. We prove that generalized attention disperses, that is, as the number of keys tends to infinity, the query assigns equal weights to all keys. Motivated by the dispersion property and recent development of Mamba form of attention, we design Scalable and Efficient Mamba like Attention (SEMA) which utilizes token localization to avoid dispersion and maintain focusing, complemented by theoretically consistent arithmetic averaging to capture global aspect of attention. We support our approach on Imagenet-1k where classification results show that SEMA is a scalable and effective alternative beyond linear attention, outperforming recent vision Mamba models on increasingly larger scales of images at similar model parameter sizes. Source code can be found at: https://github.com/nhatthanhtran/SEMA.

AES: Curing Optimizer Blindness in Long-Tailed Recognition via State-Aware Correction

Fanfu Wang, Jiachang Zhan, Zhiheng Gong, Pengkun Wang, Yang Wang

Long-tailed recognition fundamentally suffers from optimizer blindness where the optimization process mistakenly conflates the magnitude of gradient accumulation with the scarcity of semantic information. Existing strategies relying on static frequency-based priors fail to correct this bias and result in state blindness regarding supervision and micro-level blindness regarding parameter updates. To address these limitations, we propose the AES framework to establish a dynamic and state-aware correction system across the entire learning lifecycle. We specifically introduce Adaptive Residual Supervision loss to act as a real-time reality check for supervision completeness via precision shielding. We also propose Entropy-aware PCGrad to resolve parameter-level conflicts by quantifying task specificity through gradient entropy. Additionally, we devise Sample-level Conflict Arbitrated Fusion to serve as a dynamic inference arbiter that routes predictions based on instance difficulty. Extensive experiments on CIFAR-100-LT, ImageNet-LT, and iNaturalist 2018 demonstrate that our method consistently achieves state-of-the-art performance by effectively balancing head-class stability and tail-class discrimination. Code is available at [here](https://github.com/wangff0101/AES)

****

Discrete Tilt Matching

Yuyuan Chen, Shiyi Wang, Peter Potaptchik, Jaeyeon Kim, Michael Samuel Albergo

Masked diffusion large language models (dLLMs) are a promising alternative to autoregressive generation. While reinforcement learning (RL) algorithms have been

adapted to be compatible with dLLMs for fine-tuning them, their reliance on the computation of the marginal likelihood to evaluate policy objectives is intractable. To overcome this, we exploit a dynamical relation between the unmasking posterior of the base model and that which targets the reward-tilted distribution to derive Discrete Tilt Matching (DTM), an algorithm that avoids intractable likelihood evaluation entirely. DTM can be phrased as a cross-entropy loss that only requires forward evaluation of rewards and whose variance can be adaptively controlled, improving training stability. We motivate DTM on maze planning tasks, and show that fine-tuning LLaDA-8B-Instruct with DTM achieves higher accuracy at lower compute costs than prior RL-based fine-tuning methods across the Sudoku, Countdown, and MATH500 benchmarks.

Eigenvectors of Experts are Training-free Non-collapsing Routers

Giang Do, Hung Le, Truyen Tran

Sparse Mixture of Experts (SMoE) architectures improve the training efficiency of Large Language Models (LLMs) by routing input tokens to a selected subset of specialized experts. Despite their remarkable success, both training and inference in SMoE models suffer from the *expert collapse* issue (Chi et al., 2022a), which degrades model performance. Prior studies primarily focus on improving the router; however, such methods rely on training from scratch or fine-tuning, which requires high computational and data-processing costs. Furthermore, we demonstrate that, despite these efforts, the issue persists when advancing well-pretrained SMoE models, as evidenced by both theoretical and empirical results. To fill that gap, we analyze the advanced SMoE models and observe that the eigenvectors of expert weight matrices encode rich semantic information, pointing to an effective alternative to conventional routing strategies. Building on this insight, we propose **Singular Value Decomposition SMoE (SSMoE)**, a novel and *training-free* framework that leverages spectral properties of the expert weights to address the collapse issue and enhance model performance. Extensive experiments across diverse language and vision tasks, under both clean and corrupt data settings, demonstrate the strong generalization and robustness of SSMoE. Our findings highlight how a deeper understanding of model internals can guide the development of more effective SMoE architectures.

Perceptual Flow Network for Visually Grounded Reasoning

Yangfu Li, Yuning Gong, Hongjian Zhan, Teng Li, Yuanhuiyi Lyu, Tianyi Chen, Qi Liu, Ziyuan Huang, Zhihang Zhong, DanDan Zheng, Yue Lu

Despite the success of LVLMs, general optimization objectives (e.g., standard MLE) fail to constrain visual trajectories, leading to language bias and hallucination. To mitigate this, current methods introduce geometric priors from visual experts as additional supervision. However, we observe that such supervision is typically suboptimal: *it is biased toward geometric precision and offers limited reasoning utility*. To bridge this gap, we propose Perceptual Flow Network (PFlowNet), which eschews rigid alignment with the expert priors and achieves interpretable yet more effective visual reasoning. Specifically, PFlowNet decouples perception from reasoning to establish a self-conditioned generation process. Based on this, it integrates *multi-dimensional rewards* with *vicinal geometric shaping* via variational reinforcement learning, thereby facilitating reasoning-oriented perceptual behaviors while preserving visual reliability. PFlowNet delivers a provable performance guarantee and competitive empirical results, particularly setting new SOTA records on V* Bench (90.6%) and MME-RealWorld-lite (67.0%).

Real-World Unsupervised Models Generalize to Predict Brain Responses to Out-of-Distribution Stimuli

Chenggang Chen, Zhiyu Yang, Xiaoqin Wang

Deep neural networks currently provide the leading quantitative models of neural responses in sensory systems. However, these networks remain implausible as models of sensory development, largely because they rely on supervised training with label efficiency far exceeding that of biological learning. Furthermore, these models are typically trained on manually curated datasets that lack the statist

ical properties of the natural environments to which the brain is exposed. Here, we demonstrate that models trained with unsupervised objectives on real-world data significantly outperform supervised models in predicting brain responses across both human auditory and visual cortex. We show that this performance advantage is not driven by network architecture or dataset size, but rather by the data distribution. Crucially, we find that unsupervised models trained on real-world data exhibit remarkable out-of-distribution generalization: a model trained exclusively on Mandarin speech accurately predicts English-driven brain responses, and a model trained on infant head-cam footage predicts adult visual responses to curated object images. Together, our results illustrate how deep neural networks can be used to reveal the real-world statistics that shape neural representations in the brain.

Hierarchical Anchor Graph Learning for Multi-View Clustering

Xingchen Hu, Miao Jia, Jiyuan Liu, Siwei Wang, KE LIANG, Wenjing Yang

Multi-view clustering (MVC) is a fundamental task in heterogeneous data analysis, where anchor-based graph methods are widely adopted for their computational efficiency. However, existing approaches typically utilize static, single-layer anchors, failing to capture the multi-granularity nature of complex data. Drawing inspiration from hierarchical human cognition, we propose a hierarchical anchor graph learning method, termed HAG-MVC, a novel framework that organizes multi-view data as a multi-level pyramid. Unlike conventional one-shot anchor generation methods, HAG-MVC introduces a multi-level co-evolution mechanism, where anchors and graph structures are iteratively refined together to capture semantics from fine-to-coarse granularities. Moreover, HAG-MVC offers a transparent abstraction architecture as an alternative to black-box deep clustering: by maintaining all anchors within the original feature space, it enables explicit inspection of the abstraction process, ensuring inherent interpretability. Extensive experiments on benchmark datasets demonstrate that HAG-MVC consistently outperforms state-of-the-art methods. Beyond MVC, this work provides a scalable and trustworthy paradigm for hierarchical knowledge representation in broad machine learning tasks.

$\texttt{Multi}^2$: Hierarchical Multi-Agent Decision-Making with LLM-Based Agents in Interactive Environments

Sangeun Park, Minhae Kwon

A central goal of large language model (LLM) research is to build agentic systems that can plan, act, and adapt through sustained interaction with dynamic environments. While recent LLM-based agents exhibit impressive contextual reasoning, their long-horizon decision-making remains fragile, often suffering from $\texti t{objective drift}$, where goals and plans drift over extended interactions.

We introduce $\texttt{Multi}^2$, a hierarchical multi-agent decision-making framework that explicitly decomposes agent behavior into complementary roles. A high-level agent ($\texttt{System 1}$) focuses on context-aware sub-goal generation using supervised fine-tuning (SFT), while a low-level agent ($\texttt{System 2}$) executes atomic actions through offline-to-online reinforcement learning (RL) in interactive environments. This separation enables stable long-horizon control, mitigates objective drift, and allows efficient adaptation.

Across diverse interactive environments, $\texttt{Multi}^2$ consistently outperforms strong agentic baselines, demonstrating improved robustness and coordination in multi-turn interaction. Beyond performance, we introduce and release three hierarchical benchmark datasets, filling a long-standing gap in training and evaluating hierarchical decision-making for LLM-based agents.

Seg-ReSearch: Segmentation with Interleaved Reasoning and External Search

Tianming Liang, Qirui Du, Jian-Fang Hu, Haichao Jiang, Zicheng Lin, Wei-Shi Zheng

Segmentation based on language has been a popular topic in computer vision. While recent advances in multimodal large language models (MLLMs) have endowed segmentation systems with reasoning capabilities, these efforts remain confined by th

e frozen internal knowledge of MLLMs,
which limits their potential for real-world scenarios that involve up-to-date in formation or domain-specific concepts.
In this work, we propose \textbf{Seg-ReSearch}, a novel segmentation paradigm th at overcomes the knowledge bottleneck of existing approaches. By enabling interl eaved reasoning and external search, Seg-ReSearch empowers segmentation systems to handle dynamic, open-world queries that extend beyond the frozen knowledge of MLLMs.
To effectively train this capability, we introduce a hierarchical reward design that harmonizes initial guidance with progressive incentives, mitigating the dil emma between sparse outcome signals and rigid step-wise supervision.
For evaluation, we construct OK-VOS, a challenging benchmark that explicitly req uires outside knowledge for video object segmentation.
Experiments on OK-VOS and two existing reasoning segmentation benchmarks demonst rate that our Seg-ReSearch improves state-of-the-art approaches by a substantial margin.
Code and data is available at https://github.com/iSEE-Laboratory/Seg-ReSearch.

Structured Progressive Knowledge Activation for LLM-Driven Neural Architecture S earch
Zhen Liu, Yuhan Liu, Jinjun Wang, Wei Song, Jianyi Liu, Jingwen Fu
This paper focuses on a key challenge in Neural Architecture Search (NAS): integ rating established architectural knowledge while exploring new designs under exp ensive evaluations.
Large language models (LLMs) are a promising assistant for NAS because they can translate rich architectural and coding priors into executable code edits.
However, in practice, seemingly local revisions often propagate into non-local b ehavioral and performance shifts because a single edit can inadvertently couple multiple interacting functional factors, a phenomenon we refer to as functional entanglement.
To make LLM knowledge usable under such entanglement, we propose Structured Prog ressive Knowledge Activation (SPARK), which activates relevant priors by explici tly selecting the functional factor to modify and conditioning the edit on that factor.
This factor-conditioned editing reduces entangled side effects and yields more t argeted, reliable architecture modifications.
On CLRS-DFS, SPARK achieves a 28.1x sample-efficient architecture evolution spee dup and yields a 22.9% relative improvement in OOD accuracy.
Our code is available at https://github.com/AIM-ResearchLab/SPARK.

Local MAP Sampling for Diffusion Models
Shaorong Zhang, Rob Brekelmans, Greg Ver Steeg
Diffusion Posterior Sampling (DPS) provides a principled Bayesian approach to in verse problems by sampling from $p(x_0 \mid y)$. While posterior sampling is val uable for capturing uncertainty and multi-modality, many classical and practical inverse problem settings ultimately prioritize accurate point estimation—most n otably the MAP estimator, which has long served as a standard reconstruction obj ective in imaging and scientific applications. We introduce Local MAP Sampling (LMAPS), a new inference framework that iteratively solving local MAP subproblems along the diffusion trajectory. This perspective clarifies their connection to global MAP and DPS, offering a unified probabilistic interpretation for optimiza tion-based methods. Building on this foundation, we develop practical algorithms with a covariance approximation motivated by Gaussian prior assumption, a refo rmulated objective for stability and interpretability. Across a broad set of ima ge restoration and scientific tasks, LMAPS achieves state-of-the-art performance .

Gecko: A Simulation Environment with Stateful Feedback for Refining Agent Tool C alls
Zeyu Zhang, Guohao Li, Zhenchang Xing, Alexandros Apostolopoulos, Yu Lin Lee, Li

ang Zheng
The ability to use tools is fundamental for large language model (LLM) agents. Given a task, existing systems use LLMs to plan and generate tool calls, which are executed by real-world tools to complete the task. However, tool calls are prone to errors because they are generated primarily from the intrinsic capabilities of LLMs. Moreover, while it is useful to let LLMs iteratively refine the tool-call sequence using execution results from real tools, this process can be expensive and may cause unsafe side effects. To improve LLM tool calls and address issues caused by using real tools for refinement, we introduce Gecko, a stateful simulation environment that provides informative feedback for refining LLM tool calls before real execution. Specifically, Gecko combines rules and LLMs to check the validity of tool names and arguments, synthesize schema-conforming and state-consistent responses, and judge task completion against the user objective. These three types of feedback allow LLMs to refine their tool calls in simulation, forming a simple yet effective test-time scaling method named GATS. On BFCLv3 and τ^2-bench, GATS consistently improves the performance of various LLMs, including GPT-4o, GPT-5, and Gemini-3.0-pro.

VGGT-Motion: Motion-Aware Calibration-Free Monocular SLAM for Long-Range Consistency
Zhuang Xiong, Chen Zhang, Qingshan Xu, Wenbing Tao
Despite recent progress in calibration-free monocular SLAM via 3D vision foundation models, scale drift remains severe on long sequences. Motion-agnostic partitioning breaks contextual coherence and causes zero-motion drift, while conventional geometric alignment is computationally expensive. To address these issues, we propose VGGT-Motion, a calibration-free SLAM system for efficient and robust global consistency over kilometer-scale trajectories. Specifically, we first propose a motion-aware submap construction mechanism that uses optical flow to guide adaptive partitioning, prune static redundancy, and encapsulate turns for stable local geometry. We then design an anchor-driven direct Sim(3) registration strategy. By exploiting context-balanced anchors, it achieves search-free, pixel-wise dense alignment and efficient loop closure without costly feature matching. Finally, a lightweight submap-level pose graph optimization enforces global consistency with linear complexity, enabling scalable long-range operation. Experiments show that VGGT-Motion markedly improves trajectory accuracy and efficiency, achieving state-of-the-art performance in zero-shot, long-range calibration-free monocular SLAM.

DynaVieW: Schema-Guided World Modeling for Understanding Hierarchical Visual Dynamics
Silin Gao, Hao Zhao, Zeming Chen, Sepideh Mamooler, Antara Raaghavi Bhattacharya, Qiyu Wu, Hiromi Wakaki, Yuki Mitsufuji, Li Mi, Syrielle Montariol, Antoine Bosselut
Multimodal LLMs struggle to systematically model the temporal evolution of visual scenes in videos or multi-image sequences. Such inputs require models to predict or simulate multiple levels of dynamic constituents, such as actions taken in the visual sequence, and the associated changes to the visual environment that result. To address this challenge, we propose a dynamic schema-guided world model, DynaVieW, optimized for visual dynamic prediction and simulation. DynaVieW achieves an in-depth understanding of visual dynamics by learning interleaved state-transition sequences, where states cover broad visual scenes from video keyframes, and transitions capture comprehensive dynamic constituents within a hierarchical schema. DynaVieW jointly models transition prediction and state simulation under a mixture-of-experts architecture, with a cross-expert selective attention and a schema token re-weighted loss, to ensure effective and robust learning. DynaVieW's superior visual dynamic understanding boosts its downstream performances on both visual narrative creation and world simulation, showing improved consistency and controllability of visual generation and better instruction-following ability.

Ultrafast On-Chip Online Learning via Spline Locality in Kolmogorov–Arnold Networks
Duc Hoang, Aarush Gupta, Philip Harris
Ultrafast online learning is essential for high-frequency systems, such as controls for quantum computing and nuclear fusion, where adaptation must occur on sub-microsecond timescales.
Meeting these requirements demands low-latency, fixed-precision computation under strict memory constraints, a regime in which conventional Multi-Layer Perceptrons (MLPs) are both inefficient and numerically unstable.
We identify key properties of Kolmogorov-Arnold Networks (KANs) that align with these constraints.
Specifically, we show that: (i) KAN updates exploiting B-spline locality are sparse, enabling superior on-chip resource scaling, and (ii) KANs are inherently robust to fixed-point quantization.
By implementing fixed-point online training on Field-Programmable Gate Arrays (FPGAs), a representative platform for on-chip computation, we demonstrate that KAN-based online learners are significantly more efficient and expressive than MLPs across a range of low-latency and resource-constrained tasks.
To our knowledge, this work is the first to demonstrate model-free online learning at sub-microsecond latencies.
****
Task-Aware Preference Calibration for Direct Preference Optimization
Mengyang Li, Zhong Zhang, Pinlong Zhao
Direct Preference Optimization (DPO) has become a predominant approach for aligning large language models with human preferences. Recent work has used perplexity differentials to identify unreliable preference labels, but these methods apply uniform calibration strategies across all samples. We observe that the reliability of perplexity signals varies substantially across task types: perplexity differentials strongly correlate with preference quality for factual tasks but provide weak signals for creative tasks where novelty is valued. Based on this observation, we propose Task-Aware Preference Calibration (TAPC), which learns task-conditioned calibration functions that adapt to the characteristics of different prompt types. TAPC employs a task encoder to extract prompt representations and learns task-specific slope and bias parameters for mapping perplexity signals to confidence targets. Through meta-learning on a small reference dataset, TAPC discovers how to weight perplexity signals appropriately for each task category. Experiments on Llama-3-8B and Qwen2-7B demonstrate that TAPC outperforms existing methods across multiple benchmarks, with particularly large improvements on creative and open-ended tasks where uniform calibration strategies fail.

Emergent Analogical Reasoning in Transformers
Gouki Minegishi, Jingyuan Feng, Hiroki Furuta, Takeshi Kojima, Yusuke Iwasawa, Yutaka Matsuo
Analogy is a central faculty of human intelligence, enabling abstract patterns discovered in one domain to be applied to another.
However, the mechanisms underlying analogical reasoning in Transformers remain poorly understood.
In this work, inspired by the notion of functors in category theory, we formalize analogical reasoning as the inference of correspondences between entities across categories.
Based on this formulation, we introduce synthetic tasks that evaluate the emergence of analogical reasoning under controlled settings.
We find that the emergence of analogical reasoning is highly sensitive to data characteristics, optimization choices, and model scale.
Through mechanistic analysis, we show that analogical reasoning in Transformers decomposes into two key components:
(1) geometric alignment of relational structure in the embedding space, and
(2) the application of a functor within the Transformer. These mechanisms enable models to transfer relational structure from one category to another, realizing analogy.

Finally, we quantify these effects and find that the same trends are observed in pretrained LLMs.
In doing so, we move analogy from an abstract cognitive notion to a concrete, mechanistically grounded phenomenon in modern neural networks.
****
LogicSAGE: Neuro-Symbolic Reasoning with Socratic-Guided Enhancement
Jinlong Tian, Jiang Yu, Kewei Cheng, Fengxiang Cheng, Yue He, Yunfei Wang, Haotian Wang, Haoxuan Li, Wenjing Yang, Shixuan Liu
Large Language Models (LLMs) often struggle with complex logical reasoning. Existing approaches typically rely on either purely neural reasoning in natural language or offloading to formal solvers via symbolic representations. However, both paradigms face significant limitations: while LLMs exhibit strong semantic intuition they are prone to hallucinations, whereas symbolic solvers offer rigorous derivation but remain highly sensitive to minor syntactic errors. To combine the strengths of these two paradigms while mitigating their respective limitations, we introduce **LogicSAGE** (**L**ogic-informed **S**ocratic **A**gent for **G**uided **E**nhancement), a dual-process framework that integrates a robust neural reasoner (System 1) with a rigorous symbolic validator (System 2). Specifically, our framework employs a Socratic Error Correction mechanism that treats solver feedback not as terminal failures but as pedagogical signals, engaging in a dialectic loop to iteratively refine logic programs and resolve semantic ambiguities. Extensive experiments on five benchmarks show that LogicSAGE (8B) achieves a state-of-the-art 92.36% average accuracy, significantly outperforming GPT-4 baselines, which establishes that architectural innovation can supersede model scale in faithful reasoning.
****
Entropic Mirror Monte Carlo
Anas Cherradi, Yazid Janati, Alain Oliviero Durmus, Sylvain Le Corff, Yohan Petetin, Julien Stoehr
Importance sampling is a Monte Carlo method which designs estimators of expectations under a target distribution using weighted samples from a proposal distribution. When the target distribution is complex, such as multimodal distributions in high-dimensional spaces, the efficiency of importance sampling critically depends on the choice of the proposal distribution. In this paper, we propose a novel adaptive scheme for the construction of efficient proposal distributions. Our algorithm promotes efficient exploration of the target distribution by combining global sampling mechanisms with a delayed weighting procedure. The proposed weighting mechanism plays a key role by enabling rapid resampling in regions where the proposal distribution is poorly adapted to the target. Our sampling algorithm is shown to be geometrically convergent under mild assumptions and is illustrated through various numerical experiments.
****
When Does Adaptation Win? Scaling Laws for Meta-Learning in Quantum Control
Nima Leclerc, Chris Miller, Nicholas Peter Brawand
Quantum hardware suffers from intrinsic device heterogeneity and environmental drift, forcing practitioners to choose between suboptimal non-adaptive controllers or costly per-device recalibration. We derive a scaling law lower bound for meta-learning showing that the adaptation gain (expected fidelity improvement from task-specific gradient steps) saturates exponentially with gradient steps and scales linearly with task variance, providing a quantitative criterion for when adaptation justifies its overhead. Validation on quantum gate calibration shows negligible benefits for low-variance tasks but > 40% fidelity gains on two-qubit gates under extreme out-of-distribution conditions (10× the training noise), with implications for reducing per-device calibration time on cloud quantum processors. Further validation on classical linear-quadratic control confirms these laws emerge from general optimization geometry rather than quantum-specific physics. We further introduce a few-shot pre-adaptation protocol that estimates the optimal adaptation budget from $N =3–5$ probe steps within 3–19% relative error across out-of-distribution regimes.
****

RADAR: Redundancy-Aware Diffusion for Multi-Agent Communication Structure Generation

Zhen Zhang, Wanjing Zhou, Juncheng Li, Hao Fei, Jun Wen, Wei Ji

Compared with individual agents, large language model based multi-agent systems have shown great capabilities consistently across diverse tasks, including code generation, mathematical reasoning, and planning, etc. Despite their impressive performance, the effectiveness and robustness of these systems heavily rely on their communication topology, which is often fixed or generated in a single step. This restricts fine-grained structural exploration and flexible composition, resulting in excessive token utilization on simple tasks while limiting capability on complicated tasks. To mitigate this challenge, we introduce RADAR, a redundancy-aware and query-adaptive generative framework that actively reduce communication overhead. Motivated by recent progress in conditional discrete graph diffusion models, we formulate communication topology design as a step-by-step generation process, guided by the effective size of the graph. Comprehensive experiments on six benchmarks demonstrate that RADAR consistently outperforms recent baselines, achieving higher accuracy, lower token consumption, and greater robustness across diverse scenarios. Our code and data are available at https://github.com/cszhangzhen/RADAR.

Forget by Uncertainty: Orthogonal Entropy Unlearning for Quantized Neural Networks

Tian Zhang, Yujia Tong, Junhao Dong, Ke Xu, Yuze Wang, Jingling Yuan

The deployment of quantized neural networks on edge devices, combined with privacy regulations like GDPR, creates an urgent need for machine unlearning in quantized models. However, existing methods face critical challenges: they induce forgetting by training models to memorize incorrect labels, conflating forgetting with misremembering, and employ scalar gradient reweighting that cannot resolve directional conflicts between gradients. We propose $\textbf{OEU}$, a novel Orthogonal Entropy Unlearning framework with two key innovations: 1) Entropy-guided unlearning provides an unbiased forgetting direction by maximizing prediction uncertainty on forgotten data, avoiding confident misprediction toward any specific class, and 2) Gradient orthogonal projection eliminates interference by projecting forgetting gradients onto the orthogonal complement of retain gradients, providing theoretical guarantees for utility preservation under first-order approximation. Extensive experiments demonstrate that OEU outperforms existing methods in both forgetting effectiveness and retain accuracy.

****

Evaluating and Explaining Prompt Sensitivity of LLMs Using Interactions

Ruiyang Qin, Qingzhuo Wang, Tian Wang, Zhihua Wei, Wen Shen

The remarkable capabilities of large language models (LLMs) are often undermined by their instability.

Even subtle and semantically irrelevant changes in prompts can cause dramatic fluctuations in performance, a phenomenon known as prompt sensitivity. Previous studies typically evaluate prompt sensitivity by comparing the LLM's final outputs when prompts change. However, such coarse-grained metrics fail to explain the internal reasons for prompt sensitivity.

In this paper, we introduce interactions as a fine-grained tool to analyze prompt sensitivity of LLMs. Specifically, we decompose the output score of the LLM into a set of interactions. Each interaction represents a nonlinear relationship involving a set of input variables. We discover that subtle changes to prompts can trigger severe instability in interactions, even when the outputs of the LLM remain the same. To this end, we propose an Interaction-based Prompt Sensitivity (IPS) metric by quantifying changes in interactions when we introduce subtle changes to prompts.

We apply the IPS metric to 50 open-source LLMs and uncover four factors that reduce the prompt sensitivity of LLMs, including supervised fine-tuning, increased model scales, dense architectures, and few-shot learning. More crucially, we discover a common mechanism by which these four factors reduce prompt sensitivity: all four factors tend to reduce the prompt sensitivity of low-order interactions

(i.e., interactions involving few input variables).

Beyond Description: Federated Adaptation via Semantic-Visual Prototype Alignment
Jiarong Yang, Yuan Liu
Adopting pre-trained Vision-Language Models (VLMs) in Federated Learning (FL) presents a promising avenue for mitigating data scarcity and heterogeneity. However, existing solutions suffer from high computational complexity or ineffective knowledge aggregation. To address these problems, we propose FedSPA (Federated Adaptation via Semantic-Visual Prototype Alignment). On the client side, FedSPA restricts local optimization to visual prototypes, enabling lightweight personalization. On the server side, we introduce a semantic alignment module that leverages client-uploaded prototypes to minimize a contrastive objective, aligning global semantic prototypes with heterogeneous visual distributions and thereby shifting the paradigm from traditional "learning-to-describe" (optimizing static prompts) to "learning-to-align". Extensive experiments demonstrate that FedSPA significantly outperforms state-of-the-art methods in both personalized and global benchmarks, while substantially reducing computational overhead. The code is available at https://github.com/eejiarong/FedSPA-main.
****
When Attributes Disagree: Gradient Conflict in Image Aesthetic Assessment
Ye Wang, Maocai Dai, Jiang Xie, Xiuli Bi, Fei Tao, Xiao Li, Hong Yu
Image Aesthetic Assessment (IAA) predicts an image’s overall aesthetic score, yet aesthetic is influenced by multiple attributes whose relative importance varies with image content and usage scenarios. Under end-to-end training with only overall-score supervision, attribute signals are blended, which can cause gradient conflict across samples dominated by different attributes, resulting in gradient cancellation and persistent systematic bias. To address these issues, we propose AGREE (Attribute-guided Gradient Routing for Establishing Agreement), which learns attribute-specific subspaces and performs gradient routing based on sample-wise attribute sensitivity estimated via perturbation analysis. AGREE further reduces feature coupling across attributes with semantic anchors and improves robustness via error-aware reweighting. Experiments on AVA, LAPIS, AADB, TAD66K, and PARA show consistent improvements over diverse IAA baseline models, and AGREE is plug-and-play for existing end-to-end IAA methods without modifying their original architectures. To our knowledge, this work is among the early efforts in IAA to systematically study gradient conflict and provide an effective solution. The code is available at https://dahat364.github.io/AGREE/.
****
A Computational Framework for Evaluating Human-likeness in LLMs' Open-ended Human Behaviors
Yuxuan Lei, Jianxun Lian, Defu Lian, Jincenzi Wu, Tianfu Wang, Xing Xie
Large Language Models (LLMs) have found widespread application and research in scenarios such as role-playing and sociological simulations. Despite the growing use of LLM-based agents to simulate human activities, the extent to which their behaviors resemble human behavior remains underexplored. As diverse LLMs proliferate, the traditional Turing test is ineffective for scalable evaluation and prone to bias from human-crafted challenges, leading to unfair assessments. In this work, we propose a novel distribution-based framework that comprehensively evaluates human-likeness and believability of AI behaviors by leveraging large-scale open-ended human behavior data from web. For better evaluation, we design generic metrics to cover three principles: rationality, consistency, and diversity. Implemented across online shopping, open-topic Q\&A, and urban mobility, our framework reveals that even the currently best LLM still exhibits a significant gap from real user behavior, underscoring the necessity of comprehensive research and evaluation of AI’s human-like capabilities.
****
(1D) Ordered Tokens Enable Efficient Test-Time Search
Zhitong Gao, Parham Rezaei, Ali Cy, Mingqiao Ye, Nataša Jovanovi■, Jesse Allardice, Afshin Dehghan, Amir Zamir, Roman Bachmann, O■uzhan Fatih Kar
Tokenization is a key component of autoregressive (AR) generative models, conver

ting raw data into more manageable units for modeling. Commonly, tokens describe local information, such as regions of pixels in images or word pieces in text, and AR generation predicts these tokens in a fixed order. A worthwhile question is whether token structures affect the ability to steer the generation through test-time search, where multiple candidate generations are explored and evaluated by a verifier. Using image generation as our testbed, we hypothesize that recent 1D ordered tokenizers with coarse-to-fine structure can be more amenable to search than classical 2D grid structures. This is rooted in the fact that the intermediate states in coarse-to-fine sequences carry semantic meaning that verifiers can reliably evaluate, enabling effective steering during generation. Through controlled experiments, we find that AR models trained on coarse-to-fine ordered tokens exhibit improved test-time scaling behavior compared to grid-based counterparts. Moreover, we demonstrate that, thanks to the ordered structure, pure test-time search over token sequences (i.e., without training an AR model) can perform training-free text-to-image generation when guided by an image-text verifier. Beyond this, we systematically study how classical search algorithms (best-of-N, beam search, lookahead search) interact with different token structures, as well as the role of different verifiers and AR priors.

Two Calm Ends and the Wild Middle: A Geometric Picture of Memorization in Diffusion Models

Nick Dodson, Xinyu Gao, Qingsong Wang, Yusu Wang, Zhengchao Wan

Diffusion models generate high-quality samples but can also memorize training data, raising serious privacy concerns. Understanding the mechanisms governing when memorization versus generalization occurs remains an active area of research. In particular, it is unclear where along the noise schedule memorization is induced, how data geometry influences it, and how phenomena at different noise scales interact. We introduce a geometric framework that partitions the noise schedule into three regimes based on the coverage properties of training data by Gaussian shells and the concentration behavior of the posterior, which we argue are two fundamental objects governing memorization and generalization in diffusion models. This perspective reveals that memorization risk is highly non-uniform across noise levels. We further identify a danger zone at medium noise levels where memorization is most pronounced. In contrast, both the small and large noise regimes resist memorization, but through fundamentally different mechanisms: small noise avoids memorization due to limited training coverage, while large noise exhibits low posterior concentration and admits a provably near linear Gaussian denoising behavior.

For the medium noise regime, we identify geometric conditions through which we propose a geometry-informed targeted intervention that mitigates memorization.

The First Drop of Ink: Nonlinear Impact of Misleading Information in Long-Context Reasoning

Muhan Gao, Zih-Ching Chen, Kuan-Hao Huang

As large language models (LLMs) are increasingly deployed in retrieval augmented generation (RAG) and agentic systems that accumulate extensive context, understanding how distracting information affects performance in long context becomes critical. Prior work shows that semantically relevant but misleading documents can cause performance degradation, yet the quantitative relationship between the proportion of distractors and performance remains unstudied. In this work, we systematically vary the proportion of hard distractors within fixed-length contexts, revealing a striking nonlinear pattern: as the proportion of hard distractors increases, performance drops sharply within the first small fraction, while the remainder of the range yields only marginal additional decline. We term this ''The First Drop of Ink'' effect, analogous to how a single drop of ink contaminates water. We provide both theoretical and empirical analysis grounded in attention mechanics: hard distractors disproportionately capture attention even at small proportions, with diminishing marginal impact as their proportion increases. Through controlled experiments, we further show that filtering yields performance gains primarily from context length reduction rather than distractor removal, an

d only achieves substantial recovery when hard distractor proportion is reduced to near zero, which highlights the importance of upstream retrieval precision.

Scalable Medical Multimodal Fusion via Symmetric Consistency Modeling
Xiaowen Sun, Hui Liu, Gongguan Chen, Ning Mao
Medical diagnosis tasks often rely on heterogeneous information from multiple sources, such as medical images and clinical text. Multimodal fusion is therefore essential for improving classification performance and robustness. However, most existing methods assume a fixed and known modality set, making them less effective when the number or composition of modalities changes. To address this limitation, we propose a modality-agnostic medical multimodal fusion framework that can naturally accommodate an arbitrary number of input modalities. At the coarse-grained modality level, we represent each modality’s estimation of latent semantics as an uncertainty-aware probability distribution, and impose symmetric consistency constraints to achieve global cross-modal semantic alignment. At the fine-grained token level, we further design a token-level consistency constraint based on linear reconstruction. This constraint enables structured mutual verification of local semantics across modalities. Finally, for multimodal fusion, we adopt a multi-view consistency strategy to obtain a unified representation for diagnosis prediction. In particular, each modality is sequentially treated as a conditional view to suppress noise in the remaining modalities and extract shared semantics. Extensive experiments on five public and self-constructed multimodal medical datasets demonstrate the effectiveness and scalability of the proposed approach. Code is available at https://github.com/gjhgjbkg/SMMF.

Universal Approximation with Softmax Attention
Jerry Yao-Chieh Hu, Hude Liu, Hong-Yu Chen, Weimin Wu, Han Liu
We prove that with linear transformations, both (i) two-layer self-attention and (ii) one-layer self-attention followed by a softmax function are universal approximators for continuous sequence-to-sequence functions on compact domains. Our main technique is a new interpolation-based method for analyzing attention’s internal mechanism. This leads to our key insight: self-attention is able to approximate a generalized version of ReLU to arbitrary precision, and hence subsumes many known universal approximators. Building on these, we show that two-layer multi-head attention or even one-layer multi-head attention followed by a softmax function suffices as a sequence-to-sequence universal approximator. In contrast, prior works rely on feed-forward networks to establish universal approximation in Transformers. Furthermore, we extend our techniques to show that, (softmax-)attention-only layers are capable of approximating gradient descent in-context. We believe these techniques hold independent interest.

Teaching Models to Teach Themselves: Reasoning at the Edge of Learnability
Shobhita Sundaram, John Quan, Ariel Kwiatkowski, Kartik Ahuja, Yann Ollivier, Julia Kempe
RL methods for scaling large reasoning models stall on datasets with low initial success rates, and thus little training signal. We investigate a fundamental question:Can a pretrained LLM leverage latent knowledge to generate an automated curriculum for problems it cannot solve? We explore this with SOAR: An asymmetric self-play framework that uses meta-RL to surface these pedagogical signals. A teacher model proposes synthetic problems for a student model, and is rewarded with its improvement on a subset of hard problems, thus grounding the curriculum in real student progress rather than intrinsic proxy rewards. Our study on the hardest subsets of math benchmarks (0/128 success) reveals three core findings. First, it is possible to realize bilevel meta-RL that unlocks learning under sparse, binary rewards by sharpening a latent capacity of pretrained models to generate useful problems. Second, grounded rewards outperform intrinsic learnability rewards used in prior LLM self-play, reliably avoiding typical instability and diversity collapse modes. Third, the structure and well-posedness of questions are more critical for learning progress than solution correctness. Our results suggest that the ability to generate useful stepping stones does not require the pr

eexisting ability to solve the hard problems, paving a principled path to escape reasoning plateaus without additional curated data.
****
Which Algorithms Can Graph Neural Networks Learn?
Solveig Wittig, Antonis Vasileiou, Robert R Nerem, Timo Stoll, Floris Geerts, Yusu Wang, Christopher Morris
In recent years, there has been growing interest in understanding neural architectures' ability to learn to execute discrete algorithms, a line of work often referred to as neural algorithmic reasoning. The goal is to integrate algorithmic reasoning capabilities into larger neural pipelines. Many such architectures are based on (message-passing) graph neural networks (MPNNs), owing to their permutation equivariance and ability to deal with sparsity and variable-sized inputs. However, much existing work is either largely empirical and lacks formal guarantees or it focuses solely on expressivity, leaving open the question of when and how such architectures generalize beyond a finite training set. In this work, we propose a general theoretical framework that characterizes sufficient conditions under which MPNNs can learn an algorithm from a training set of small instances and provably approximate its behavior on inputs of arbitrary size with worst-case guarantees. Our framework applies to a broad class of algorithms, including single-source shortest paths, minimum spanning trees, and general dynamic programming problems, such as the 0-1 knapsack problem. In addition, we establish impossibility results for a wide range of algorithmic tasks, showing that standard MPNNs cannot learn them and derive more expressive MPNN-like architectures that overcome these limitations. Finally, we refine our analysis for the Bellman–Ford algorithm, yielding substantially smaller required training sets and significantly extending the recent work of Nerem et al., 2025 by allowing for a differentiable regularization loss. Empirical results largely support our theoretical findings.
****
Aitchison Embeddings for Learning Compositional Graph Representations
Nikolaos Nakis, Chrysoula Kosma, Panagiotis Promponas, Michail Chatzianastasis, Giannis Nikolentzos
Representation learning is central to graph machine learning, powering tasks such as link prediction and node classification. However, most graph embeddings are hard to interpret, offering limited insight into how learned features relate to graph structure. Many networks naturally admit a role-mixture view, where nodes are best described as mixtures over latent archetypal factors. Motivated by this structure, we propose a compositional graph embedding framework grounded in Aitchison geometry, the canonical geometry for comparing mixtures. Nodes are represented as simplex-valued compositions and embedded via isometric log-ratio (ILR) coordinates, which preserve Aitchison distances while enabling unconstrained optimization in Euclidean space. This yields intrinsically interpretable embeddings whose geometry reflects relative trade-offs among archetypes and supports coherent behavior under component restriction; we consider both fixed and learnable ILR bases. Across node classification and link prediction, our method achieves competitive performance with strong baselines while providing explainability by construction rather than post hoc. Finally, subcompositional coherence enables principled component restriction: removing and renormalizing subsets preserves a well-defined geometry, which we exploit via subcompositional dimensionality removal to probe how archetype groups influence representations and predictions.

PPT-Eval: A Benchmark for Computer-Use Agents on PowerPoint Tasks
Apurva Gandhi, Vishwas Suryanarayanan, Raja Hasnain Anwar, Firoz Shaik, Shubhang Desai, Thong Q. Nguyen, Muhammad Taqi Raza, Vishal Chowdhary, Graham Neubig
Creating and editing slides is a rich, multimodal activity that is ubiquitous in professional and educational settings, making it an ideal testbed for real-world computer-use agents. Microsoft PowerPoint is among the most widely adopted and feature-rich environments for presentation creation. We introduce PPT-Eval, a benchmark of 120 PowerPoint tasks across 12 files that cover both content creation and presentation editing scenarios, organized by difficulty. A central challen

ge in this domain is evaluation: tasks are complex, multimodal, and often admit many valid solutions. Moreover, today’s agents frequently make only partial progress, which binary success metrics fail to capture. To address this, we design a robust evaluation framework to help create task-specific rubrics for PowerPoint tasks, taking inspiration from and building on past works for rubric-based evaluation. These rubrics award partial credit for intermediate steps, penalize unnecessary changes and poor aesthetics, and provide natural language feedback. This nuanced approach proves highly effective, achieving a Kendall's τ_b correlation of 0.77 with human judgments. We find that existing frontier agents still struggle with solving PowerPoint tasks, with strong models like Claude-4.5-Opus achieving only a 45\% success rate and an average partial score of 57\%.
****

MuonSSM: Orthogonalizing State Space Models for Sequence Modeling
Thai Khanh Nguyen, Vo Ngoc Bich Uyen, Thieu Vo, Tan Minh Nguyen, Cuong Pham
State space models (SSMs) have emerged as efficient linear-time alternatives to attention for long-sequence modeling. However, existing SSMs often suffer from instability and memory degradation over extended horizons due to poorly conditioned first-order updates and unbalanced update geometry. We introduce MuonSSM, a general framework that stabilizes SSM training by explicitly conditioning the geometry of memory updates rather than the recurrent transition matrix. MuonSSM augments SSMs with a momentum-based pathway and a lightweight Newton-Schulz transformation on low-rank input injections, yielding bounded and spectrally conditioned updates while preserving parallel scan complexity. Theory shows that MuonSSM improves gradient propagation, mitigates spectral amplification, and enriches memory representations over long horizons. Extensive experiments across language, vision, and time-series benchmarks show consistent gains in accuracy, robustness, and long-context performance when integrated into diverse SSM backbones. These results establish geometric conditioning of updates as a principled pathway to stable, scalable sequence modeling.
****

ViTok-v2: Scaling Native Resolution Autoencoders to 5 Billion Parameters
Philippe Hansen-Estruch, Jiahui Chen, Vivek Ramanujan, Orr Zohar, Markos Georgopoulos, Animesh Sinha, Ji Hou, Edgar Schönfeld, Felix Juefei-Xu, Sriram Vishwanath, Ali Thabet
Vision Transformer (ViT) tokenizers offer a scalable alternative to convolutional auto-encoders, yet current architectures have two key limitations: their performance degrades when images vary in aspect ratio or resolution, and their reliance on adversarial losses makes them harder to train at scale. To address this, we introduce ViTok-v2, a ViT tokenizer building on ViTok. We add native resolution support via NaFlex with 2D RoPE and stabilize training by replacing the standard LPIPS-plus-discriminator objective with our novel DINO perceptual loss. We scale our model to 5B parameters, training the largest ViT-based image compression autoencoder to date and demonstrate continued improvements with scale. In downstream generation experiments with flow matching models, we find that smaller generators perform best with aggressive channel compression while larger generators effectively leverage higher channel counts. ViTok-v2 matches state-of-the-art reconstruction at 256p and outperforms across benchmarks at 512p and higher resolutons, while remaining compatible with any pipeline requiring flexible aspect ratios.

Constitutional Black-Box Monitoring for Scheming in LLM Agents
Simon Storf, Rich Barton-Cooper, James Peters-Gill, Marius Hobbhahn

Safe deployment of Large Language Model (LLM) agents in autonomous settings requires reliable oversight mechanisms. A central challenge is detecting *scheming*, where agents covertly pursue misaligned goals. One approach to mitigating such risks is LLM-based monitoring: using language models to examine agent behaviors for suspicious actions. We study *constitutional black-box monitors*: prompted classifiers that detect scheming using only externally observable inputs and outputs, optimized on synthetic data generated from natural-language behavior specifications. We introduce two pipelines for generating synthetic agent trajectories, *STRIDE* (iterative refinement) and *Gloom* (agent-environment simulation), from which we generate 1,000 samples each. We optimize monitors on these datasets via prompt sweeps, human refinement, and automated prompt optimization, and evaluate performance on 7,500 held-out trajectories from Control Arena, a suite of grounded environments where agents operate in more realistic contexts. Our results demonstrate that monitors selected purely on synthetic data can generalize to more realistic environments, capturing a meaningful scheming signal. However, we find that performance saturates quickly in our setting, with simple prompt sweeps matching the results of more extensive optimization. Pushing beyond this limit yields no further improvements and instead leads to overfitting.

ProMeCD: Unifying Long-Tailed and Noisy Label Learning via White-Box Control

Yu Zhu

Real-world data is rarely clean; it is plagued by severe class imbalance (long-tailed distributions) and label corruption. Current solutions lean heavily on "black-box" meta-learning to re-weight samples. However, this paradigm introduces a fatal circular dependency: it relies on pristine, balanced validation sets to guide the optimization, which are essentially non-existent in the wild. We propose ProMeCD, a self-referential framework that breaks this dependency by recasting optimization as an autonomous control problem. Instead of training an opaque neural meta-learner, we employ a transparent proportional-integral controller. The system monitors ``cognitive entropy'' that is a metric derived from von Mises-Fisher gradient statistics to assess learning uncertainty. To resolve the scalar ambiguity between tail and noisy samples, ProMeCD employs a decoupled control strategy: it boosts tail classes via integral accumulation of magnitude deficits when directional consistency is high, while suppressing noise via proportional feedback when consistency collapses. Theoretically, we prove that this mechanism guarantees convergence and formally prevents the minority initial drop, ensuring monotonic improvement for rare classes. Crucially, ProMeCD is fully white-box and validation-free. Experiments on CIFAR-LT, iNaturalist, CIFAR-N, mini WebVision, and Clothing1M confirm that ProMeCD is not merely efficient; it outperforms the recent meta-learner FMW-Net by over 10\% in severe imbalance settings, proving that explicit control theory offers a superior path to handling imperfect data.

MusicDET: Zero-Shot AI-Generated Music Detection

Chaolei Han, Hongsong Wang, Jie Gui

Detecting AI-generated music is crucial for preserving artistic authenticity and preventing the misuse of generative music technologies. However, existing discriminative detectors typically rely on generated samples during training and often suffer from severe performance degradation when confronted with music produced by unseen generators, which limits their real-world applicability.

To address this issue, we formulate a zero-shot setting for AI-generated music detection, where the detector is trained exclusively on real music without access to any generated samples. Under this setting, we propose MusicDET, a generator-agnostic detection framework based on frequency-guided normalizing flows that probabilistically models the distribution of real music features. By evaluating the likelihood of an input sample under the learned real-music distribution, MusicDET enables effective detection of out-of-distribution music signals.

Experiments on the FakeMusicCaps and SONICS datasets show that MusicDET consistently outperforms conventional discriminative detectors, particularly when detecting music generated by previously unseen models.

The code is at https://github.com/Chaolei98/MusicDET

Learning to Bet for Horizon-Aware Anytime-Valid Testing
Ege Onur Taga, Samet Oymak, Shubhanshu Shekhar
We develop horizon-aware anytime-valid tests and confidence sequences for bounded means under a strict deadline N. Using the betting/e-process framework, we cast horizon-aware betting as a finite-horizon optimal control problem with state space $(t, \log W_t)$, where t is the time and W_t is the test martingale value. We first show that in certain interior regions of the state space, policies that deviate significantly from Kelly betting are provably suboptimal, while Kelly betting reaches the threshold with high probability. We then identify sufficient conditions showing that outside this region, more aggressive betting than Kelly can be better if the bettor is behind schedule, and less aggressive can be better if the bettor is ahead. Taken together these results suggest a simple phase diagram in the $(t, \log W_t)$ plane, delineating regions where Kelly, fractional Kelly, and aggressive betting may be preferable. Guided by this phase diagram, we introduce a Deep Reinforcement Learning approach based on a universal Deep Q-Network (DQN) agent that learns a single policy from synthetic experience and maps simple statistics of past observations to bets across horizons and null values. In limited-horizon experiments, the learned DQN policy yields state-of-the-art results.
****
Robust Filter Attention: Self-Attention as Precision-Weighted State Estimation
Peter Racioppo
We introduce Robust Filter Attention (RFA), a formulation of self-attention as a robust state estimator. Each token is treated as a noisy observation of a latent trajectory governed by a linear stochastic differential equation (SDE), and attention weights are determined by consistency under this model rather than static feature similarity. Under isotropic noise and decay assumptions, RFA matches the computational complexity of standard attention. On language modeling benchmarks, RFA achieves lower perplexity than RoPE within the training window while remaining stable under zero-shot extrapolation to longer contexts. The framework also provides a dynamical interpretation of standard positional mechanisms, connecting rotational embeddings and recency biases to transport and uncertainty propagation induced by stochastic dynamics.
****
DARC: Disagreement-Aware Alignment via Risk-Constrained Decoding
mingxi Zou, Jiaxiang Chen, Junfan Li, Langzhang Liang, Qifan Wang, Xu Yinghui, Zenglin Xu
Preference-based alignment methods (e.g., RLHF, DPO) typically optimize a single scalar objective, implicitly averaging over heterogeneous human preferences. In practice, systematic annotator and user-group disagreement makes mean-reward maximization brittle and susceptible to proxy over-optimization. We propose **Disagreement-Aware Alignment via Risk-Constrained Decoding (DARC)**, a retraining-free inference-time method that frames response selection as distributionally robust, risk-sensitive decision making. Given multiple preference samples or scalable disagreement proxies, DARC reranks candidates by maximizing a *KL-robust (entropic)* satisfaction objective, and provides simple deployment controls that cap or penalize the corresponding entropic risk premium relative to the mean, enabling explicit risk budgets without retraining. We provide theoretical characterization linking this decoding rule to principled pessimism and KL-based distributionally robust optimization. Experiments on alignment benchmarks show that DARC reduces disagreement and tail risk while maintaining competitive average quality under noisy, heterogeneous feedback.
****
MindFlow: Mind Supernet Powered Thinking Flows for Research Idea Innovation
Mengdi Liu, Wenjue Chen, Wenyue Chen, Cheng Yang, Fanqi Kong, Zhangyang Gao, Xiaoxue Cheng, Yiheng Li, Yujian Yuan, Keliang Li, Hong Chang, Shiguang Shan, Chenglin Wu
Research idea innovation is a fundamental engine of scientific progress, yet it remains difficult to generate and evaluate in a scalable and controllable way. T

his challenge lies in its inherently open-ended and multi-objective nature, where ideas should balance novelty, plausibility and feasibility. While recent LLM-based approaches have made progress through carefully designed prompts or agent pipelines, they are constrained by predefined, static ideation workflows. To address this limitation, we propose MindFlow, a framework that explicitly formulates ideation as a graph-structured Flow in Mind, which is composed of modular thinking operators and modeled by a probabilistic mind supernet. Given a research topic, a controller dynamically samples thinking flows to generate candidate ideas. This open-ended problem is optimized using a tournament-based relative ranking, enabling the controller to progressively favor higher-quality thinking flows. We further introduce an evaluation protocol that jointly assesses problem finding and problem solving, going beyond title- or abstract-only judgments. Across diverse topics, MindFlow shows its superiority as an explicit, controllable and optimizable research idea innovator.

WorldPlay: Towards Long-Term Geometric Consistency for Real-Time Interactive World Modeling

Wenqiang Sun, Haiyu Zhang, Haoyuan Wang, Junta Wu, Zehan Wang, Zhenwei Wang, Yunhong Wang, Jun Zhang, Tengfei Wang, Chunchao Guo

This paper presents WorldPlay, a streaming video diffusion model that enables real-time, interactive world modeling with long-term geometric consistency, resolving the trade-off between speed and memory that limits current methods. WorldPlay draws power from three key ingredients. 1) We use a Dual Action Representation to enable robust action control in response to the user's keyboard and mouse inputs. 2) To enforce long-term consistency, our Reconstituted Context Memory dynamically rebuilds context from past frames and uses temporal reframing to keep geometrically important but long-past frames accessible, effectively alleviating memory attenuation. 3) We also propose Context Forcing, a novel distillation method designed for memory-aware model. Aligning memory context between the teacher and student preserves the student's capacity to use long-range information, enabling real-time speeds while preventing error drift. Taken together, WorldPlay generates long-horizon streaming 720p video at 24 FPS with superior consistency, comparing favorably with existing techniques and showing strong generalization across diverse scenes. Project page and online demo can be found: https://3d-models.hunyuan.tencent.com/world/ and https://3d.hunyuan.tencent.com/sceneTo3D.

AMA-Bench: Evaluating Long-Horizon Memory for Agentic Applications

Yujie Zhao, Boqin Yuan, Junbo Huang, Haocheng Yuan, Zhongming Yu, Haozhou Xu, Lanxiang Hu, Abhilash Shankarampeta, Zimeng Huang, Wentao Ni, Yuandong Tian, Jishen Zhao

Large Language Models (LLMs) are increasingly used as autonomous agents in complex, long-horizon applications, where effective memory is critical for sustained performance. Yet existing memory benchmarks are largely dialogue-centric, while real agent memory consists of continuous agent-environment interaction trajectories composed of states, actions, observations, and tool outputs. To address this gap, we introduce **AMA-Bench** (**A**gent **M**emory with **A**ny length), a benchmark for evaluating long-horizon memory in realistic agentic settings. AMA-Bench combines real-world agent trajectories from representative applications with expert-curated QA, as well as synthetic trajectories that scale to arbitrary horizons with rule-based QA. Our study shows that existing memory systems underperform because they fail to capture causal and objective information and rely heavily on lossy similarity-based retrieval. We further propose **AMA-Agent**, a memory system based on causality-graph construction and tool-augmented retrieval. AMA-Agent achieves **57.22%** accuracy on AMA-Bench, outperforming the strongest baseline by **11.16%**. Resources are available at: https://ama-bench.github.io/.

LMM4-IC4K: A Large Multimodal Model Powered Integrated Circuit Footprint Geometry Understanding

Yida Wang, Taiting Lu, Runze Liu, Lanqing Yang, Zhe Chen, Yuehai Wang, Yixin Liu

, Kaiyuan Lin, XiaoMeng Chen, Dian Ding, Yijie Li, Yifan Yang, Yi-Chao Chen, yin cheng jin, Mahanth Gowda
Printed-Circuit-board (PCB) footprint geometry labeling of integrated circuits (IC) is essential in defining the physical interface between components and the P CB layout, requiring precise visual perception. However, the unstructured nature of footprint drawings and abstract diagram annotations prevents direct IC footp rint parsing and automated package geometry labeling methods from developing. Ex isting Large Multimodal Models (LMMs) struggle with inaccurate geometric percept ion, limiting their effectiveness in this task. To address these challenges, we propose LMM4-IC4K, a novel framework that treats IC mechanical drawings as image s and leverages LMMs for structured geometric interpretation. To support such a framework, we introduce ICGeo8K, a multi-modal dataset with 8,608 labeled sample s, including 4138 real-world IC footprint samples and 4470 synthetically generat ed samples. We further present a two-stage training framework to fine-tune LMMs for IC footprint labeling. Extensive experiments demonstrate that our model outp erforms state-of-the-art LMMs on the proposed benchmark. The accurate translatio n of footprint diagrams enabled by LMM4-IC4K contributes to advancing automation and standardization within the PCB industry.

Interactive Segmentation with Elaborate Focus Prior
Kangpeng Hu, Yinghui Sun, Tao Wang, Weihao Zhang, Quansen Sun
Regional refinement for interactive segmentation is of great necessity to ensure the fidelity of segmented pixels nearby user-prompted locations, which specifie s a local window (focus view) for the latest click after a global prediction, w here local pixels are revisited and optimized using numerous refining structures . Previous methods either utilize a two-stage pipeline to estimate the focus vie w or manually preset a fixed scope for all clicks, while the former is time-cons uming, the latter fails to capture the correlation among click position, object geometry, and focus intensity. In this paper, we inherit the core idea of FCFI a nd dedicate a one-stage framework characterized with Elaborate Focus Prior (EFPN et). Concretely, EFPNet outputs an erroneous mask w.r.t historical feedback and newly-placed click in an end-to-end manner, which deduces precise focus region a ccording to its max-connected component, followed with feedback correction consi dering image, feature and mask affinity. We further design a clicked-with-focus mechanism for efficient feedback integration. Extensive studies on four benchmar ks have revealed outstanding performance of EFPNet for both efficacy and computa tional overhead.

Prior Diffusiveness and Regret in the Linear-Gaussian Bandit
Yifan Zhu, John Duchi, Benjamin Van Roy
We prove that Thompson sampling exhibits $\tilde{O}(\sigma d \sqrt{T} + d r \sqr t{\mathrm{Tr}(\Sigma_0)})$ Bayesian regret in the linear-Gaussian bandit with a $\mathcal{N}(\mu_0, \Sigma_0)$ prior distribution on the coefficients, where d is the dimension, T is the time horizon, r is the maximum ℓ_2 norm of the actions, and σ^2 is the noise variance. In contrast to existing regre t bounds, this shows that to within logarithmic factors, the prior-dependent ''b urn-in'' term $d r \sqrt{\mathrm{Tr}(\Sigma_0)}$ decouples additively from the m inimax (long run) regret \sigma d \sqrt{T}. Previous regret bounds exhibit a mul tiplicative dependence on these terms. We establish these results via a new ''el liptical potential'' lemma, and also provide a lower bound indicating that the b urn-in term is unavoidable.

Dynamics of neural scaling laws in random feature regression with powerlaw-distr ibuted kernel eigenvalues
Jakob Kramp, Javed Lindner, Moritz Helias
Training large neural networks exposes neural scaling laws for the generalizatio n error, which points to a universal behavior across network architectures of le arning in high dimensions. It was also shown that this effect persists in the li mit of highly overparametrized networks as well as the Neural network Gaussian p rocess limit. We here develop a principled understanding of the typical behavior

of generalization in Neural Network Gaussian process regression dynamics. We de
rive a dynamical mean-field theory that captures the typical case learning dynam
ics: This allows us to unify multiple existing regimes of learning studied in th
e current literature, namely Bayesian inference on Gaussian processes, gradient
flow with or without weight-decay, and stochastic Langevin training dynamics. Em
ploying tools from statistical physics, the unified framework we derive in eithe
r of these cases yields an effective description of the high-dimensional microsc
opic behavior of networks dynamics in terms of lower dimensional order parameter
s. We show that collective training dynamics may be separated into the dynamics
of N independent eigenmodes, whose evolution equations are only coupled through
collective response functions and a common statistics of an effective, independe
nt noise. Our approach allows us to quantitatively explain the dynamics of the g
eneralization error by linking spectral and dynamical properties of learning on
data with power law spectra, including phenomena such as neural scaling laws and
the effect of early stopping.

GFMate: Empowering Graph Foundation Models with Test-time Prompt Tuning
Yan Jiang, Ruihong Qiu, Zi Huang
Graph prompt tuning has shown great potential in graph learning by introducing t
rainable prompts to enhance the model performance in conventional single-domain
scenarios. Recent research has extended graph prompts to improve Graph Foundatio
n Models (GFMs) by few-shot tuning auxiliary prompts. Despite their progress, mo
st existing methods embed source-domain information into prompts, which serve ei
ther as input to GFMs or encoded during model pre-training. Such prompt entangle
ment with specific source domains and GFM pre-training strategy restricts their
generalisability to other domains and different GFMs. Furthermore, existing GFM
prompts merely rely on few-shot tuning for adaptation, neglecting the rich infor
mation in unlabelled target domain test data. Motivated by these insights, this
paper aims to empower GFMs with pre-training-agnostic test-time graph prompt tun
ing, named GFMate. GFMate introduces centroid and layer prompts applied after pr
e-training on target domains, avoiding entanglement with specific source domains
and model pre-training. In addition, a test-time complementary learning objecti
ve is devised to exploit both labelled and unlabelled target domain data for eff
ective test-time prompt tuning. Extensive experiments on 12 benchmark datasets d
emonstrate the superior performance and efficiency of GFMate, achieving improvem
ents of up to 30.63%. Code is available at https://github.com/YanJiangJerry/GFMa
te.

Desirable Effort Fairness and Optimality Trade-offs in Strategic Learning
Valia Efthymiou, Ekaterina Fedorova, Chara Podimata
Strategic classification examines how decision rules interact with agents who st
rategically adapt their features. Most existing models focus on maximizing predi
ctive performance, assuming agents best respond to the learned classifier. Howev
er, real decision-making systems are rarely optimized solely for accuracy: ethic
al, economic, and institutional considerations often make some feature changes m
ore desirable than others. At the same time, principals may wish to incentivize
these changes fairly across heterogeneous agents.
While prior work has studied causal structure between features, notions of desir
ability, and information disparities in isolation, this work initiates a unified
treatment of these components within a single framework. We frame the problem a
s a constrained optimization problem that captures the trade-offs between optima
lity, desirability, and fairness.
We provide theoretical guarantees on the principal's optimality loss constrained
to a particular desirability fairness tolerance for multiple broad classes of f
airness measures. Finally, through experiments on real datasets, we show the exp
licit tradeoff between maximizing accuracy and fairness in desirability effort.

An analytic theory of convolutional neural network inverse problems solvers
Minh Hai Nguyen, Quoc Bao Do, Edouard Pauwels, Pierre Weiss
Supervised convolutional neural networks (CNNs) are widely used to solve imaging

inverse problems, achieving state-of-the-art performance in numerous applications. However, despite their empirical success, these methods are poorly understood from a theoretical perspective and often treated as black boxes. To bridge this gap, we analyze trained neural networks through the lens of the Minimum Mean Square Error (MMSE) estimator, incorporating functional constraints that capture two fundamental inductive biases of CNNs: translation equivariance and locality via finite receptive fields. Under the empirical training distribution, we derive an analytic, interpretable, and tractable formula for this constrained variant, termed Local-Equivariant MMSE (LE-MMSE). Through extensive numerical experiments across various inverse problems (denoising, inpainting, deconvolution), datasets (FFHQ, CIFAR-10, FashionMNIST), and architectures (U-Net, ResNet, PatchMLP), we demonstrate that our theory matches the neural networks outputs (PSNR $\gtrsim25$ dB). Furthermore, we provide insights into the differences between *physics-aware* and *physics-agnostic* estimators, the impact of high-density regions in the training (patch) distribution, and the influence of other factors (dataset size, patch size, *etc*).
****

Learning Transferable Interaction Primitives from Game Videos for Humanoid Locomotion
Xiangming Zhu, Huayu Deng, Haoran Zhao, Yiwei Hao, Yunbo Wang
Learning humanoid control from video provides a scalable alternative to the scarcity of high-fidelity robot data. Existing methods, however, often rely on curated datasets and treat video as passive kinematic priors. They fail to capture dynamic humanoid interactions with the environment, which are essential for robust control in complex physical environments. To address this, we propose ***TR**ansferable **I**nteraction **P**rimitives (TRIP)*, a framework designed to extract and ground interactions from unlabeled game videos for locomotion control. TRIP explicitly models dependencies between motion dynamics and environmental context via a discrete library of interaction-based action primitives. To bridge the reality gap, we introduce a shared context latent space that aligns implicit video-domain features with functional target-domain observations, enabling the seamless transfer of video-mined strategies to reinforcement learning policies. Our experiments on complex terrain navigation demonstrate that TRIP achieves significant improvements in task performance, sample efficiency, and robustness.

GRAPE: Let GRPO Supervise Query Rewriting by Ranking for Retrieval
Zhaohua Zhang, Jianhuan Zhuo, Muxi Chen, Chenchen Zhao, Wenyu Jiang, Mingyang Chen, Yu Tang, Qiuyong Xiao, Tianwen Jiang, Jihong Zhang, Zhixun Su
The CLIP model has established itself as a cornerstone of large-scale retrieval systems. However, its performance often degrades under distributional shifts such as multilingual, long-form, or multimodal queries. To avoid the prohibitive costs associated with retriever retraining or corpus re-embedding, we propose GRAPE (Grouped Ranking-Aware Policy Optimization Enhancement), a plug-and-play approach that leverages LLM-based query rewriting to bridge these gaps. Unlike existing methods that lack explicit supervision, GRAPE integrates ranking signals into the rewriting LLM via Grouped Relative Policy Optimization (GRPO), ensuring rewritten queries are better aligned with the frozen retriever’s latent distribution. Crucially, we identify a score inflation phenomenon in naive similarity-based finetuning—where irrelevant candidates receive indiscriminately high scores—and mitigate it with a novel corpus-relative ranking-based reward. Extensive experiments across multilingual (Flickr30k-CN, CVLUE, XM3600), long-form (Wikipedia), and multimodal (CIRR) benchmarks demonstrate that GRAPE consistently improves performance, achieving an average gain of 4.9% in Recall@10 without any modification to the underlying retriever.The code is available at https://github.com/mogulzhang/GRAPE.

Achieving Logarithmic Regret in KL-Regularized Zero-Sum Markov Games
Anupam Nayak, Tong Yang, Osman Yagan, Gauri Joshi, Yuejie Chi
Reverse Kullback–Leibler (KL) divergence-based regularization with respect to a fixed reference policy is widely used in modern reinforcement learning to preser

ve the desired traits of the reference policy and sometimes to promote explorati on (using uniform reference policy, known as entropy regularization). Beyond ser ving as a mere anchor, the reference policy can also be interpreted as encoding prior knowledge about good actions in the environment. In the context of alignme nt, recent game-theoretic approaches have leveraged KL regularization with pretr ained language models as reference policies, achieving notable empirical success in self-play methods. Despite these advances, the theoretical benefits of KL re gularization in game-theoretic settings remain poorly understood. In this work, we develop and analyze algorithms that provably achieve improved sample efficien cy under KL regularization. We study both two-player zero-sum Matrix games and M arkov games:
for Matrix games, we propose OMG, an algorithm based on best response sampling w ith optimistic bonuses, and extend this idea to Markov games through the algorit hm SOMG, which also uses best response sampling and a novel concept of superopti mistic bonuses. Both algorithms achieve a logarithmic regret in T that scales inversely with the KL regularization strength β
in addition to the traditional $\widetilde{\mathcal{O}}(\sqrt{T})$ regret withou t the β^{-1} dependence.

The Signal is in the Steps: Local Scoring for Reasoning Data Selection
Hoang Anh Just, Myeongseob Ko, Ruoxi Jia
Distilling long-form reasoning from teacher models into smaller students require s selecting which candidate solutions to train on. Recent work argues that one s hould select responses the student model assigns highest probability, i.e., favo ring solutions ``natural'' to the student. However, we find that this approach w orks within a single teacher but fails when scaling to long reasoning traces fro m multiple diverse teachers. We identify a key cause: this approach scores entir e solutions, but students generalize by recombining familiar reasoning steps, no t by memorizing complete solutions. Full-trajectory scoring optimizes the wrong target; it rewards global fluency while the transferable signal lies in local st ep transitions. We propose Local Average Log Probability (LALP), which scores ea ch reasoning step using only a small window of preceding context, measuring whet her each step is justified by its immediate premises rather than whether the ful l response looks natural to the student. LALP enables two practical use cases: s electing the best teacher before fine-tuning and curating training data from div erse teacher pools. Across math, coding, and science reasoning tasks, LALP consi stently improves accuracy when selecting the most natural solutions by a large m argin.

Failure-Driven Workflow Refinement
Jusheng Zhang, Kaitong Cai, Jing Yang, Ziliang Chen, Yongsen Zheng, Kwok-Yan Lam , Liang Lin, Keze Wang
Workflow optimization for tool-using LLM agents is often cast as global search o ver candidate graphs, scored by a scalar metric. This collapses rich, multi-step failure traces into binary outcomes, obscuring recurring failure structure and making refinement inefficient. We reframe optimization as \emph{distributional r efinement}: each workflow induces a density over a \textbf{Failure Signature Spa ce} $\mathcal{F}$, and the goal is to minimize its \textbf{Expected Failure Mass }. We propose \textbf{CE-Graph}, which maintains a counterexample pool, estimate s dense failure modes, and applies operator-constrained graph edits via a \textb f{Propose-and-Verify} loop with a convergence-aware stopping rule. Across math, code, and QA benchmarks, CE-Graph improves robustness while reducing optimizatio n cost compared to strong workflow-search baselines, suggesting reliability emer ges from learning and reshaping failure landscapes rather than merely maximizing aggregate success rates.

Does Math Reasoning Improve General LLM Capabilities? Understanding Transferabil ity of LLM Reasoning
Maggie Ziyu Huan, Yuetai Li, Tianyu Zheng, Xiaoyu Xu, Seungone Kim, Minxin Du, R adha Poovendran, Graham Neubig, Xiang Yue

Math reasoning has become the poster child of progress in large language models (LLMs), with new models rapidly surpassing human-level performance on benchmarks like MATH and AIME. But as math leaderboards improve week by week, it is worth asking: do these gains reflect broader problem-solving ability or just narrow overfitting? To answer this question, we evaluate over 20 open-weight reasoning-tuned models across a broad suite of tasks, including math, scientific QA, agent planning, coding, and standard instruction-following. We surprisingly find that most models that succeed in math fail to transfer their gains to other domains. To rigorously study this phenomenon, we conduct controlled experiments using math-only data with two widely-used methods: Reinforcement Learning (RL) and Supervised Finetuning (SFT) with detailed ablations. On top of the observation that RL-tuned models transfer better than SFT-tuned models, we identify on-policy fine-tuning as the key mechanism underlying cross-domain transfer, regardless of whether the training signal comes from RL or supervised learning. Latent-space representation and token-space distribution shift analyses reveal that off-policy SFT induces substantial representation and output drift, while on-policy RL preserves general-domain structure. Our results suggest a need to rethink the post-training recipes, particularly the reliance on off-policy SFT-distilled data to advance reasoning models.

Train Once, Reuse Everywhere: Generalizable Implicit ICL by Routing Attention

Jiaqian Li, Yanshu Li, Ligong Han, Ruixiang Tang, Wenya Wang

Implicit in-context learning (ICL) has newly emerged as a promising paradigm that simulates ICL behaviors in the representation space of large language models (LLMs), aiming to attain few-shot performance at zero-shot cost. However, existing approaches largely rely on injecting shift vectors into residual flows, which are typically constructed from labeled demonstrations or task-specific alignment. Such designs fall short of utilizing the structural mechanisms underlying ICL and suffer from limited generalizability. To address this, we propose In-Context Routing (ICR), a novel implicit ICL method that internalizes generalizable ICL patterns at the attention logits level. It extracts reusable structural directions that emerge during ICL and employs a learnable input-conditioned router to modulate attention logits accordingly, enabling an efficient train-once-and-reuse framework. We evaluate ICR on 12 real-world datasets spanning diverse domains and multiple LLMs. The results show that ICR consistently outperforms existing implicit ICL methods that require task-specific retrieval or training, while demonstrating robust generalization to out-of-domain tasks where they struggle. These findings position ICR to push the boundary of the practical value of ICL.

Accelerating Langevin Monte Carlo via Efficient Stochastic Runge-Kutta Methods beyond Log-Concavity

Bin Yang, Xiaojie Wang

Sampling from a high-dimensional probability distribution is a fundamental algorithmic task arising in wide-ranging applications across
multiple disciplines, including scientific computing, computational statistics and machine learning. Langevin Monte Carlo (LMC) algorithms are among the most widely used sampling methods in high-dimensional settings. This paper introduces a novel higher-order and Hessian-free LMC sampling algorithm based on an efficient stochastic Runge--Kutta method of strong order 1.5 for the overdamped Langevin dynamics. In contrast to the existing Runge--Kutta type LMC of Li et al. (2019) involved with three gradient evaluations, the newly proposed algorithm is computationally cheaper and requires only two gradient evaluations at each iteration. Under certain log-smooth conditions, non-asymptotic error bounds of the proposed algorithms are analyzed in $\mathcal{W}_2$-distance. In particular, a uniform-in-time convergence rate of order $O(d ^{\frac32} h^{\frac32})$ is derived in a non-log-concave setting, matching the convergence rate proved in the aforementioned work but under the log-concavity condition. Numerical experiments are finally presented to demonstrate the effectiveness of the new sampling algorithm.

Milestone-Guided Policy Learning for Long-Horizon Language Agents

Zixuan Wang, Yuchen Yan, Hongxing Li, Teng Pan, Dingming Li, Ruiqing Zhang, Weiming Lu, Jun Xiao, Yueting Zhuang, Yongliang Shen
While long-horizon agentic tasks require language agents to perform dozens of sequential decisions, training such agents with reinforcement learning remains challenging. We identify two root causes: credit misattribution, where correct early actions are penalized due to terminal failures, and sample inefficiency, where scarce successful trajectories result in near-total loss of learning signal. We introduce a milestone-guided policy learning framework, BEACON, that leverages the compositional structure of long-horizon tasks to ensure precise credit assignment. BEACON partitions trajectories at milestone boundaries, applies temporal reward shaping within segments to credit partial progress, and estimates advantages at dual scales to prevent distant failures from corrupting the evaluation of local actions. On ALFWorld, WebShop, and ScienceWorld, BEACON consistently outperforms GRPO and GiGPO.
Notably, on long-horizon ALFWorld tasks, BEACON achieves 92.9\% success rate, nearly doubling GRPO's 53.5\%, while improving effective sample utilization from 23.7\% to 82.0\%. These results establish milestone-anchored credit assignment as an effective paradigm for training long-horizon language agents. Code is in supplementary materials and will be publicly released.

ProtocolBench: Which LLM MultiAgent Protocol to Choose?
Hongyi Du, Jiaqi Su, Jisen Li, Lijie Ding, Yingxuan Yang, Peixuan Han, Xiangru Tang, Kunlun Zhu, Jiaxuan You
As large-scale multi-agent systems evolve, the communication protocol layer has become a critical yet under-evaluated factor shaping performance and reliability. Despite the existence of diverse protocols (A2A, ACP, ANP, Agora, etc.), the selection of them is often intuition-driven and lacks standardized guidance. We introduce ProtocolBench, a benchmark that systematically compares agent protocols along four measurable axes: task success, end-to-end latency, message or byte overhead, and robustness under failures. On ProtocolBench, the choice of protocol significantly influences system behavior. In the Streaming Queue scenario, overall completion time varies by up to 36.5\% across protocols, and mean end-to-end latency differs by 3.48 s. Under Fail-Storm Recovery, resilience also differs consistently across protocols. Beyond evaluation, we present ProtocolRouter, a lightweight constraint-aware protocol router that selects per-scenario (or per-module) protocols from requirement and runtime signals. ProtocolRouter reduces Fail-Storm recovery time by up to 18.1\% versus the best single-protocol baseline and achieves scenario-specific gains such as higher success in GAIA, while exposing trade-offs across other metrics. We also release ProtocolRouterBench to standardize constrained protocol-selection evaluation and improve reliability at scale.
****
Probabilistic Salient Object Ranking
Rongjin Guo, Guan Huankang, Rynson W. H. Lau
Salient Object Ranking (SOR) aims to study how humans visually explore complex scenes by predicting an ordered sequence of objects that attracts our attention. Existing SOR approaches typically model this ranking deterministically, assuming a single, fixed ranking sequence of attention. However, such deterministic SOR fails to capture the true nature of human attention. We observe that human attention shifts exhibit variability and stochasticity, i.e., the next object of fixation is not a definitive choice but rather a probability distribution. Yet, existing SOR methods and evaluation metrics do not account for this inherent randomness. To address this fundamental problem, we first propose ProbSOR, a novel Probabilistic Salient Object Ranking framework built upon a vision-language model (VLM) backbone. By incorporating Group Relative Policy Optimization (GRPO), ProbSOR explicitly learns the uncertainty of attention shifts. We then propose a new metric tailored for ProbSOR, as existing SOR metrics only support deterministic rankings. We further construct a ProbSOR dataset comprising 15,000 probabilistic SOR samples, to support both model training and evaluation. Extensive experiments show that ProbSOR achieves strong performance in salient object ranking under

both our proposed and traditional benchmarks.

PrivAct: Internalizing Contextual Privacy Preservation via Multi-Agent Preferenc e Training
Yuhan Cheng, Hancheng Ye, Hai Helen Li, Jingwei Sun, Yiran Chen
Large language model (LLM) agents are increasingly deployed in personalized task s involving sensitive, context-dependent information, where privacy violations m ay arise in agents' action due to the implicitness of contextual privacy.
Existing approaches rely on *external*, inference-time interventions which are b rittle, scenario-specific, and may expand the privacy attack surface.
We propose **PrivAct**, a contextual privacy-aware multi-agent learning framewor k that *internalizes* contextual privacy preservation directly into models' gene ration behavior for privacy-compliant agentic actions. By embedding privacy pref erences into each agent, PrivAct enhances system-wide contextual integrity while achieving a more favorable privacy-helpfulness tradeoff.
Experiments across multiple LLM backbones and benchmarks demonstrate consistent improvements in contextual privacy preservation, reducing leakage rates by up to 12.32\% while maintaining comparable helpfulness, as well as zero-shot generali zation and robustness across diverse multi-agent topologies.
Code is available at https://github.com/chengyh23/PrivAct.

High-Accuracy Sampling for Diffusion Models and Log-Concave Distributions
Fan Chen, Sinho Chewi, Constantinos Costis Daskalakis, Alexander Rakhlin
We present algorithms for diffusion model sampling which obtain δ-error i n $\mathrm{polylog}(1/\delta)$ steps, given access to $\widetilde O(\delta)$-acc urate score estimates in L^2. This is an exponential improvement over all prev ious results. Specifically, under minimal data assumptions, the complexity is $\ widetilde O(d\mathrm{polylog}(1/\delta))$ where d is the dimension of the data ; under a non-uniform L-Lipschitz condition, the complexity is $\widetilde O(\ sqrt{dL}\mathrm{polylog}(1/\delta))$; and if the data distribution has intrinsic dimension $d_\star$, then the complexity reduces to $\widetilde O(d_\star\mathr m{polylog}(1/\delta))$. Our approach also yields the first $\mathrm{polylog}(1/\ delta)$ complexity sampler for general log-concave distributions using only grad ient evaluations.

Less is Enough: Synthesizing Diverse Data in LLM Feature Space with Sparse Autoe ncoders
Zhongzhi Li, Xuansheng Wu, Yijiang Li, Lijie Hu, Ninghao Liu
The diversity of post-training data is critical for effective downstream perform ance in large language models (LLMs).
Many existing approaches to constructing post-training data quantify diversity u sing text-based metrics that capture linguistic variation, but such metrics prov ide only weak signals for the task-relevant features that determine downstream p erformance.
In this work, we introduce ***Feature Activation Coverage* (FAC)** which measure s data diversity in an interpretable feature space.
Building upon this metric, we further propose a diversity-driven data synthesis framework, named **FAC Synthesis**, that first uses a sparse autoencoder to iden tify missing features from a seed dataset, and then generates synthetic samples that explicitly reflect these features.
Experiments show that our approach consistently improves both data diversity and downstream performance on various tasks, including instruction following, toxic ity detection, reward modeling, and behavior steering.
Interestingly, we identify a shared, interpretable feature space across model fa milies (i.e., LLaMA, Mistral, and Qwen), enabling cross-model knowledge transfer .
Our work provides a solid and practical methodology for exploring data-centric o ptimization of LLMs.

InertialAR: Autoregressive 3D Molecule Generation with Inertial Frames

Haorui Li, weitao Du, Yuqiang Li, Hongyu Guo, Shengchao Liu
Transformer-based autoregressive models have emerged as a unifying paradigm across modalities such as text and images, but their extension to 3D molecule generation remains underexplored. The gap stems from two fundamental challenges: (1) how to tokenize molecules into a canonical 1D sequence of tokens that is invariant to both SE(3) transformations and atom index permutations, and (2) how to design an architecture capable of modeling hybrid atom-based tokens that couple discrete atom types with continuous 3D coordinates. To address these challenges, we introduce InertialAR. It first performs generation-oriented canonical tokenization by aligning each molecule to a canonical inertial frame and reordering atoms, thereby converting arbitrary 3D structures into a unique, SE(3)- and permutation-invariant sequence of tokens for autoregressive generation. Built upon this canonical tokenization, we propose geometric positional encoding (GeoPE), which endows Transformer attention with 3D geometric awareness. Finally, InertialAR utilizes a hierarchical autoregressive paradigm to decode the next atom, consecutively predicting the atom type and 3D coordinates via Diffusion Loss. Experimentally, InertialAR achieves state-of-the-art performance on 8 of the 10 evaluation metrics for unconditional generation across QM9, GEOM-Drugs, and B3LYP. Moreover, it significantly outperforms baselines in controllable generation for targeted chemical functionality, attaining state-of-the-art results across all 5 metrics. Code is available at github.com/HaoruiLi46/InertialAR.

Matrix-Free GPU Semidefinite Programming for Quantum Ordered Search at the k=6 Frontier
Yancheng Wu, Huikang Liu, Wenzhi Gao, Yuexin Su, Tongyang Li, Dongdong Ge, Yinyu Ye
Quantum computation offers the potential for a significant constant-factor speedup for the Ordered Search Problem (OSP). A classical construction is the k-query quantum ordered search algorithm, which can exactly search an N-element ordered list and achieves a query complexity improvement of a factor of $\frac{k}{\log_2 N}$. For larger k, stronger constant-factor improvements could be obtained by finding the largest admissible list size $N^\star$, a task that can be formulated as a structured semidefinite program (SDP). However, solving this SDP becomes computationally intractable beyond $k=6$, as existing CPU and GPU solvers rely on explicit construction of prohibitively large constraint matrices.
In this paper, we introduce a matrix-free GPU SDP framework that evaluates the highly structured constraints in OSP on-the-fly using custom CUDA kernels, reducing memory complexity from quadratic to linear and shifting the bottleneck from memory to computation. Using this approach, we provide strong numerical evidence that the optimal list size for $k=6$ is at least $90,000$, improving the empirical upper bound on the query coefficient from 0.390 to 0.365. We further rigorously certify the upper bound $N^\star < 94,000$ by constructing dual infeasibility certificates via matrix-free minimum-eigenvalue estimation.

CentaurEval: Benchmarking Human-in-the-Loop Value in Agentic Coding
Hanjun Luo, Chiming Ni, Jiaheng Wen, Zhimu Huang, Bingduo Liao, Sylvia Chung, Yiran Wang, Yingbin Jin, Jialin Li, Xinfeng Li, Wenyuan Xu, XiaoFeng Wang, Hanan Salam
LLM-powered coding agents are reshaping the development paradigm. However, existing evaluation systems, neither traditional tests for humans nor benchmarks for LLMs, fail to capture this shift, excluding problems that require both human reasoning to guide solutions and AI efficiency for implementation. We introduce CentaurEval, a unified, ecologically valid benchmark for measuring human-in-the-loop value in coding. CentaurEval's core innovation is its "Collaboration-Necessary" problem templates, which are intractable for standalone LLMs or humans, but solvable through effective collaboration. CentaurEval dynamically instantiates tasks from 45 templates, providing a standardized IDE for humans and a reproducible 450-task toolkit for LLMs. We benchmark 45 participants against 5 LLMs under 4 levels of human intervention. Results show that while LLMs or humans alone achieve poor pass rates (0.67% and 18.89%), human–AI collaboration significantly impr

oves to 31.11%. Our analysis reveals an emerging co-reasoning partnership, chall enging the traditional human-tool hierarchy by showing that strategic breakthrou ghs can originate from either humans or AI.
****
Bullet Trains: Parallelizing Training of Temporally Precise Spiking Neural Netwo rks
Todd Morrill, Christian-Gernot Pehle, Anthony M. Zador
Continuous-time, event-native spiking neural networks (SNNs) operate strictly on spike events, treating spike timing and ordering as the representation rather t han an artifact of time discretization. This viewpoint aligns with biological co mputation and with the native resolution of event sensors and neuromorphic proce ssors, while enabling compute and memory that scale with the number of events. H owever, two challenges hinder practical, end-to-end trainable event-based SNN sy stems: 1) exact charge--fire--reset dynamics impose inherently sequential proces sing of input spikes, and 2) precise spike times must be solved without time bin s. We address both. First, we use parallel associative scans to consume multiple input spikes at once, yielding up to 44x speedups over sequential simulation wh ile retaining exact hard-reset dynamics. Second, we implement differentiable spi ke time solvers that compute spike times to machine-precision without discrete-t ime approximations or restrictive analytic assumptions. We demonstrate the viabi lity of training SNNs using our solutions on four event-based datasets on GPUs.

Efficient Skill Grounding via Code Refactoring with Small Language Models
Sera Choi, Wonje Choi, Saehun Chun, Daehee Lee, Jooyoung Kim, Chaeun Lee, Honguk Woo
Effective skill grounding is essential for deploying reusable skills in embodied agents, as even minor embodiment or environmental differences can render an ent ire skill incompatible.
This challenge is particularly pronounced in embodied settings, where agents mus t operate in dynamic, partially observable environments without access to large language models (LLMs).
In this setting, reliance on LLMs is impractical, while small language models (s LMs) remain insufficient for the effective skill grounding required for reliable long-horizon control.
We present RECENT, a refactoring-centric agent framework that enables efficient skill grounding with sLMs by decoupling skill semantics from embodiment- and env ironment-specific execution binding.
By representing skills as executable code, RECENT preserves the semantic intent encoded in a skill’s control structure while grounding it by modifying only exec ution bindings through localized refactoring, rather than regenerating code from scratch.
We evaluate RECENT across diverse skill grounding scenarios spanning multiple ro bot embodiments in dynamic environments, demonstrating robust long-horizon perfo rmance when deployed with an sLM.
Across all scenarios, RECENT achieves the best performance among sLM-based Code-as-Policies (CaP) methods and matches the task performance of LLM-based CaP.

SlideSparse: Fast and Flexible (2N-2):2N Structured Sparsity
Yingbo Hao, Hanyong Shao, Ting Song, Yan Xia, Di Zhang, Shaohan Huang, Xun Wu, S ongchen Xu, Le Xu, Li Dong, Zewen Chi, Yi Zou, Furu Wei
NVIDIA's 2:4 Sparse Tensor Cores deliver $2\times$ throughput but demand strict 50% pruning—a ratio that causes severe accuracy loss in LLMs. Milder $(2N-2):2N$ patterns (e.g., 6:8, 25% pruning) preserve accuracy far better—within 0.4–1.8 a verage points of dense in our Qwen2.5-7B/14B study—yet receive *NO* hardware sup port and fall back to dense execution. We present **SlideSparse**, the first sys tem to unlock Sparse Tensor Core acceleration for the $(2N-2):2N$ model family o n commodity GPUs. Our *Sliding Window Decomposition* rewrites any $(2N-2):2N$ we ight block into $N-1$ overlapping 2:4-compliant windows without changing the und erlying dot product; in addition, our *Activation Lifting* fuses the correspondi ng activation rearrangement into per-token quantization at low marginal cost. In

tegrated into vLLM, **SlideSparse** is evaluated across various GPUs (A100, H100, B200, RTX 4090, RTX 5080, DGX-spark), precisions (FP4, INT8, FP8, BF16, FP16), and model families (Llama, Qwen, BitNet). On compute-bound workloads, the measured speedup ($1.33\times$) matches the theoretical upper-bound $N/(N-1)=4/3$ at 6:8 weight sparsity in Qwen2.5-7B, establishing $(2N-2):2N$ as a practical path to better accuracy–speedup trade-offs in LLM acceleration. Code available at https://github.com/bcacdwk/vllmbench.

Federated Distillation for Whole Slide Image via Gaussian-Mixture Feature Alignment and Curriculum Integration

Luru Jing, Cong Cong, Yanyuan Chen, Yongzhi Cao

Federated learning (FL) offers a promising framework for collaborative digital pathology by enabling model training across institutions. However, real-world deployments face heterogeneity arising from diverse multiple instance learning (MIL) architectures and heterogeneous feature extractors across institutions. We propose FedHD, a novel FL framework that performs local Gaussian-mixture feature alignment tailored for WSI analysis. Instead of exchanging model parameters, each client independently distills semantically rich synthetic feature representations aligned with the distribution of real WSIs. To preserve diagnostic diversity, FedHD adopts a one-to-one distillation strategy, generating a synthetic counterpart for each real slide to avoid over-compression. During federation, a curriculum-based integration strategy progressively incorporates cross-site synthetic features into local training once performance plateaus. Furthermore, an optional interpretation module reconstructs pseudo-patches from synthetic embeddings, enhancing transparency. FedHD is architecture-agnostic, privacy-preserving, and supports personalized yet collaborative training across diverse institutions. Experiments on TCGA-IDH, CAMELYON16, and CAMELYON17 show that FedHD consistently outperforms state-of-the-art federated and distillation baselines.

Scaling up Multi-Turn Off-Policy RL and Multi-Agent Tree Search for LLM Step-Provers

Ran Xin, Zeyu Zheng, Yanchen Nie, Kun Yuan, Xia Xiao

The integration of Large Language Models (LLMs) with automated theorem proving has shown immense promise, yet is constrained by challenges in scaling up both training-time reinforcement learning (RL) and inference-time compute. This paper introduces BFS-Prover-V2, a step-level theorem proving system designed to address this dual scaling problem. We present two primary innovations. The first is a novel multi-turn off-policy RL framework for continually improving the performance of the LLM step-prover at training time. This framework, inspired by the principles of AlphaZero, utilizes a multi-stage expert iteration pipeline featuring adaptive tactic-level data filtering and periodic retraining to surmount the performance plateaus that typically curtail long-term RL in LLM-based agents. The second innovation is a planner-enhanced multi-agent system that scales reasoning capabilities at inference time. This architecture employs a general reasoning model as a high-level planner to iteratively decompose complex theorems into a sequence of simpler subgoals. This hierarchical approach substantially reduces the search space, enabling a team of parallel prover agents to collaborate efficiently by leveraging a shared proof cache. We demonstrate that this dual approach to scaling yields state-of-the-art results on established formal mathematics benchmarks. BFS-Prover-V2 achieves 95.08% and 41.4% on the miniF2F and ProofNet test sets respectively. While demonstrated in the domain of formal mathematics, the RL and inference techniques presented in this work are of broader interest and may be applied to other domains requiring long-horizon multi-turn reasoning and complex search.

DFSAttn: Dynamic Fine-grained Sparse Attention for Efficient Video Generation

Jie Hu, Zixiang Gao, Yutong He, Kun Yuan

Diffusion transformers have achieved remarkable success in high-quality video generation, yet their reliance on spatiotemporal 3D full attention incurs prohibitive computational cost due to the quadratic complexity of attention. Block spars

e attention is a common approach to mitigate this by focusing computation on imp
ortant regions. However, attention maps in DiTs exhibit inherently dynamic and f
ine-grained sparsity, which causes existing block sparse attention methods to de
grade significantly in quality, especially at high sparsity ratios. In this pape
r, we revisit block sparse attention and derive a theoretical lower bound on att
ention recall to characterize the key factors governing its effectiveness. Guide
d by these insights, we propose DFSAttn, a training-free sparse attention framew
ork that enables dynamic, fine-grained sparsification efficiently. DFSAttn incor
porates three core designs: Hilbert curve-based token reordering to achieve fine
-grained sparsity while preserving efficient GPU execution, hierarchical block s
coring for accurate block importance estimation, and sparse mask caching with ad
aptive ratios to balance accuracy and efficiency. Experimental results demonstra
te that DFSAttn consistently outperforms prior methods under high sparsity, achi
eving up to 2.1$\times$ end-to-end speedup while maintaining high generation qua
lity. Our code is open-sourced and available at https://github.com/jessica-hujie
/DFSAttn.

Butterworth as Attention: Anisotropic Spectral Gating for Pansharpening
Zhenggang Wang, Wu Wang, Huazhe Liang, Tai-Xiang Jiang
Pansharpening fuses high-resolution panchromatic
(PAN) images with low-resolution multispectral
(LMS) images. For spatial-spectral fusion,
Fast Fourier Transform (FFT)-based methods
provide a global receptive field to capture
long-range dependencies and naturally separate
frequency components. However, most existing
approaches directly transplant spatial operators
like convolution or self-attention, while disregarding
the fundamental structure of the spectrum:
a strict spatial correspondence where each coordinate
represents a specific frequency component,
and a highly non-uniform, radially decaying
energy distribution. To address this, we revisit
the classical Butterworth filter, a frequencydomain
operator defined directly on spectral coordinates
that is inherently suited for processing
such structured representations. We generalize
the standard isotropic Butterworth filter into an
anisotropic, learnable frequency-domain gating
mechanism, establishing an efficient alternative
to self-attention, and propose the Anisotropic Butterworth
Fusion Network (ABFNet). Its core
is a novel dual-branch gating module that employs
learnable anisotropic Butterworth filters
to perform adaptive direction-aware feature selection,
integrating global context and local details
with linear complexity. Extensive experiments
show that ABFNet achieves state-of-the-art
(SOTA) performance on pansharpening benchmarks
with low computational overhead. Furthermore,
its superior accuracy on CIFAR-100
classification validates the broader applicability
of this frequency-domain learning paradigm.
****
Efficient Code Analysis via Graph Representation Learning-Guided Large Language
Models
Hang Gao, Tao Peng, Baoquan Cui, Hong Huang, Fengge Wu, Junsuo Zhao, Jian Zhang
Large Language Models (LLMs) have significantly advanced code analysis tasks, ye
t they struggle to detect malicious behaviors fragmented across files, whose int
ricate dependencies easily get lost in the vast amount of benign code. We theref

ore propose a graph-centric attention acquisition pipeline that enhances LLMs' a bility to localize malicious behavior. The approach parses a project into a code graph, uses an LLM to encode nodes with semantic and structural signals, and tr ains a Graph Neural Network (GNN) under sparse supervision. The GNN performs an initial detection, and by interpreting these predictions, identifies key code se ctions that are most likely to contain malicious behavior. These influential reg ions are then used to guide the LLM's attention for in-depth analysis. This stra tegy significantly reduces interference from irrelevant context while maintainin g low annotation costs. Extensive experiments show that the method consistently outperforms existing approaches on multiple public and custom datasets, highligh ting its potential for practical deployment in software security scenarios. Code s can be found in https://github.com/Epiphaniespt/GMLLM.git.

Towards Multimodal Large Language Models with Both Training and Inference Effici ency

Qianhao Yuan, Yanjiang Liu, Guozhao Mo, Yaojie Lu, Hongyu Lin, Jia Zheng, Ben He , Xianpei Han, Le Sun

Multimodal Large Language Models (MLLMs) mainly fall into two architectures, eac h involving a trade-off between training and inference efficiency: embedding spa ce alignment (e.g. LLaVA series) is inefficient during inference, while cross-at tention space alignment (e.g. Flamingo) is inefficient in training. A primary di fference between them lies in whether each visual token attends to other tokens within the LLM backbones. To investigate whether this form of attention is essen tial for MLLMs, we propose NAEViT (No AttEntion from Visual Tokens), an attentio n mechanism that eliminates such interactions. Our pilot experiment shows that a ttention from visual tokens
is highly redundant. Then, we introduce SAISA (Self-Attention Input Space Alignm ent), a novel architecture that enhances both training and inference efficiency. SAISA directly aligns visual features with the input spaces of NAEViT attention blocks, reducing computational overhead in both attention and FFNs. We conduct experiments on various baseline models, model sizes and training datasets. SAISA achieves superior performance compared to the baselines, while significantly re ducing computational costs. Further ablation studies validate the effectiveness of SAISA across various LLMs and visual encoders.

The Geometric Origin of Grokking: Accelerating Generalization via Active Structu ral Reorganization

Kefei Tao, Zhang Zhang, Mingze Qi, Xiaojun Duan

Grokking, the phenomenon where models suddenly generalize long after overfitting training data, remains a puzzling challenge in neural network dynamics. Through mechanistic analysis, we find that this transition is fundamentally driven by a structural reorganization of token representations, with the onset of grokking entailing a shift toward a well-defined geometry, and reveal the model’s distinc t understanding of data’s dual characteristics. Building on these geometric insi ghts, we propose R2G (Repel-to-Grokking) Loss, an active intervention that resha pes the representation manifold by enforcing structural repulsion. The versatili ty of R2G is empirically validated in both algorithmic and linguistic tasks, whi le our theoretical analysis and ablation studies jointly demonstrate that angula r reorganization is the primary driver of grokking. Our work offers a novel mech anistic perspective on the evolution of grokking and provides a useful tool for enhancing model efficiency and reliability.

Model-Free Robust Average-Reward Reinforcement Learning with Sample Complexity A nalysis

Zachary Andrew Roch, George K. Atia, Yue Wang

Robust reinforcement learning (RL) under the average-reward criterion is essenti al for long-term decision-making, particularly when the environment may differ f rom its training dynamics. However, most existing studies focus on model-based s ettings and provide only asymptotic guarantees, hindering their principled under standing and practical deployment, especially in data-limited scenarios. We aim

to close this gap by proposing a model-free algorithm, **Robust Halpern Iteratio n (RHI)**. We first design our algorithm based on a black-box sampling oracle, w hich can estimate the worst-case performance accurately. We then derive the fini te sample complexity of RHI under the generative model setting, assuming the sam pling oracle. To concretely design such an oracle, we propose a K-order multi- level Monte-Carlo estimator, which is shown to have a lower bias compared to pri or methods. We further instantiate our design for multiple uncertainty models, i ncluding KL and χ^2 divergence sets, and show that our RHI algorithm achiev es an ε-optimal robust policy with a sample complexity of $\tilde{\m athcal{O}}\left(\frac{SA\mathcal{H}^2}{\varepsilon^{(2+o(1))}}\right)$, where $ S,A$ are the number of states and actions, and $\mathcal{H}$ is the robust optim al span. Our result asymptotically matches the best complexity in robust average reward RL.

Bridging Time and Frequency: A Joint Modeling Framework for Irregular Multivaria te Time Series Forecasting

Xiangfei Qiu, Kangjia Yan, Xvyuan Liu, Xingjian Wu, Jilin Hu

Irregular multivariate time series (IMTS) forecasting is challenging due to non- uniform sampling and variable asynchronicity. These irregularities violate the e quidistant assumptions of standard models, hindering local temporal modeling and rendering classical frequency-domain methods ineffective for capturing global p eriodic structures. To address this challenge, we propose TFMixer, a joint time–frequency modeling framework for IMTS forecasting. Specifically, TFMixer incorpo rates a Global Frequency Module that employs a learnable Non-Uniform Discrete Fo urier Transform (NUDFT) to directly extract spectral representations from irregu lar timestamps. In parallel, the Local Time Module introduces a query-based patc h attention mechanism to adaptively aggregate informative temporal segments and alleviate information density imbalance. Finally, TFMixer fuses the time-domain and frequency-domain representations to generate forecasts and further leverages inverse NUDFT for explicit seasonal extrapolation. Extensive experiments on rea l-world IMTS benchmarks demonstrate the effectiveness and robustness of TFMixer under irregular sampling and missing data.

Optimal Learning from Label Proportions with General Loss Functions

Lorne Applebaum, Travis Dick, Claudio Gentile, Haim Kaplan, Tomer Koren

Motivated by problems in online advertising, we address the task of Learning fro m Label Proportions (LLP). We introduce a novel and versatile low-variance debia sing methodology to learn from aggregate label information, significantly advanc ing the state of the art in LLP. Our debiasing approach exhibits remarkable flex ibility, seamlessly accommodating a broad spectrum of practically relevant loss functions across both binary and multi-class classification settings. By careful ly combining our estimators with standard techniques, we improve sample complexi ty guarantees for a large class of losses of practical relevance. We also empiri cally validate the efficacy of our proposed approach across a diverse array of b enchmark datasets, demonstrating compelling empirical advantages over standard b aselines.

Inverting Data Transformations via Diffusion Sampling

Jinwoo Kim, Sékou-Oumar Kaba, Jiyun Park, Seunghoon Hong, Siamak Ravanbakhsh

We study the problem of transformation inversion on general Lie groups: a datum is transformed by an unknown group element, and the goal is to recover an invers e transformation that maps it back to the original data distribution. Such unkno wn transformations arise widely in machine learning and scientific modeling, whe re they can significantly distort observations. We take a probabilistic view and model the posterior over transformations as a Boltzmann distribution defined by an energy function on the data space. To sample from this posterior, we introdu ce a diffusion process on Lie groups that keeps all updates on-manifold and only requires computations in the associated Lie algebra. Our method, Transformation -Inverting Energy Diffusion (TIED), relies on a new trivialized target-score ide ntity that enables efficient score-based sampling of the transformation posterio

r. As a key application, we focus on test-time equivariance, where the objective is to improve the robustness of pretrained neural networks to input transformations. Experiments on image homographies and PDE symmetries demonstrate that TIED can restore transformed inputs to the training distribution at test time, showing improved performance over strong canonicalization and sampling baselines.

A Theory of Contrastive Learning with Natural Images

Antonio Torralba, Yair Weiss

Why does contrastive learning with simple images and augmentations yield useful representations for downstream tasks? We address this question by analytically computing the optimal representation in terms of the contrastive loss for a range of basic augmentations and any image dataset with stationary statistics. We show that for certain augmentations the optimum can be attained by a CNN whose first layer filters are sinusoids, followed by a pointwise nonlinearity, global average pooling, and a final linear layer that performs partial whitening. We also show that the optimal weights in such CNNs for more complicated augmentations are still sinusoids. The frequencies of the sinusoids and their weights can be computed using a simple “waterfilling” algorithm given the dataset’s expected power spectrum. Experiments with different image datasets and augmentations show that such CNNs trained with SGD empirically learn sinusoids in their first layer and to perform partial whitening.

MiniMax Learning of Interpretable Factored Stochastic Policies from Conjoint Data, with Uncertainty Quantification

Connor Thomas Jerzak, Priyanshi Chandra, Rishi Hazra

We study offline policy optimization over exponentially large factorial action spaces from randomized preference data, showing how conjoint experiments can estimate interpretable stochastic policies with asymptotically valid uncertainty under regularity conditions. Conjoint analyses typically report Average Marginal Component Effects (AMCEs) by averaging over opponent attributes and thus ignore strategic interdependence. We instead learn *stochastic interventions*—product-of-Categorical policies over factor levels—that (i) optimize expected outcomes in an average-case setting and (ii) extend to a two-player *minimax* (adversarial) setting that realistically captures simultaneous strategic candidate selection. Methodologically, we derive a closed-form optimizer for a tractable two-way interaction regime with L_2 variance regularization, and provide a general gradient-based procedure for richer model classes. Uncertainty from the outcome model propagates asymptotically to both the optimal policy and its value via a Delta method approximation. We further model institutional details (e.g., primaries) inside the minimax objective and introduce a data-driven measure of strategic divergence between parties. On synthetic data, we empirically characterize finite-sample error and coverage as dimensionality and n vary. On a U.S. presidential conjoint, adversarially learned policies produce restricted-equilibrium vote shares that align with historical election ranges in our data, in stark contrast to non-adversarial (averaging) optimizers.

SERA: Soft-Verified Efficient Repository Agents

Ethan Shen, Daniel Tormoen, Saurabh Shah, Ali Farhadi, Tim Dettmers

Open-weight coding agents should hold a fundamental advantage over closed-source systems because they can specialize to private codebases, encoding repository-specific information directly in their weights. Yet the cost and complexity of training has kept this advantage theoretical until now. We present Soft-Verified Efficient Repository Agents (SERA), an efficient method for training coding agents that enables the rapid and cheap creation of agents specialized to private codebases. Using Soft Verified Generation (SVG), we generate thousands of trajectories from any code repository, without requiring unit tests. Beyond repository specialization, we apply SVG to a larger corpus of codebases, generating 200,000+ synthetic trajectories. Using only supervised finetuning (SFT), SERA achieves leading results among fully open-source (open data, method, code) models while matching the performance of open-weight models like Devstral-Small-2. Creating SERA

models is 26x cheaper than reinforcement learning and 57x cheaper than previous synthetic data methods to reach equivalent performance. We use our dataset to provide detailed analysis of scaling laws, ablations, and confounding factors for training coding agents. Overall, we believe our work will greatly accelerate research on open coding agents and showcase the advantage of open-source models that can adapt to private codebases.

Opt-Miner: Empowering Information-Seeking Agent with Tree-Guided Data Synthesis for Optimization Modeling

Haoyang Liu, Yuyang Cai, Jie Wang, Xiongwei Han, Minyang Hu, Shuqi LIU, Mingxuan Yuan, Jianye HAO, Feng Wu

Large Language Model (LLM) agents have shown significant potential in automated optimization modeling for mathematical problems. However, real-world problems are still challenging due to their knowledge-intensive nature. Existing methods, constrained by static parametric knowledge, often lack the domain expertise required to comprehend complex scenarios and apply appropriate mathematical techniques, leading to errors.

To address this challenge, we propose the Opt-Miner framework, where the agent learns to identify missing knowledge, retrieve technical documents on the web, and ground its mathematical models for improved modeling performance.

The core of Opt-Miner is a novel tree-guided data synthesis pipeline coupled with a retrieval-based group relative policy optimization (R-GRPO) algorithm, designed to foster the agent’s information-seeking capabilities.

Specifically, we first formulate each problem into a tree structure, with its scenario contexts and mathematical techniques embedded in subtrees.

We then employ subtree union, transfer, and knowledge fogging to synthesize complex, multi-domain problems that incorporate knowledge gaps, thereby necessitating active information seeking to solve these problems.

Based on synthesized data, we propose R-GRPO for agent reinforcement learning. Experiments demonstrate that Opt-Miner-Qwen3-8B achieves performance comparable to 32B state-of-the-art specialized agents and commercial reasoning models.

Fast and Near-Optimal Algorithms for Private Hypothesis Selection

Hilal Asi, Hongjie Chen

We study the problem of private hypothesis selection: given samples from an unknown distribution drawn from a finite hypothesis class, the goal is to identify the best hypothesis under the constraint of differential privacy. Existing algorithms for this problem are either computationally expensive or achieve sub-optimal statistical rates. We propose new algorithms that achieve near-optimal rates while running in nearly linear time in the number of hypotheses. Rather than applying the exponential mechanism directly with a score function that requires pairwise comparisons between hypotheses, our approach introduces a carefully designed loss function based on a small set of strong hypotheses. This structure allows the score to be evaluated efficiently for most hypotheses, yielding significant computational savings. We further extend our algorithms to the agnostic setting, where the true distribution may not belong to the hypothesis class. As an application, we obtain faster differentially private algorithms for universal statistical estimation in low dimensional settings.

Offline Reinforcement Learning with Universal Horizon Models

Hojun Chung, Junseo Lee, Songhwai Oh

Model-based reinforcement learning (RL) offers a compelling approach to offline RL by enabling value learning on imagined on-policy trajectories. However, it often suffers from compounding errors due to repeated model inference on self-generated states. While geometric horizon models (GHM) alleviate this issue through direct prediction over a discounted infinite-horizon future, they remain challenged in accurately modeling distant future states. To this end, we introduce universal horizon models (UHM), a generalization of GHM that directly predicts future states under arbitrary horizons. Leveraging this flexibility, we propose a scalable value learning method that employs a winsorized horizon distribution to st

abilize training by capping excessively large horizons. Experimental results on 100 challenging OGBench tasks demonstrate that the proposed method outperforms competitive baselines, particularly on tasks with highly suboptimal datasets and those requiring long-horizon reasoning. Project page: https://rllab-snu.github.io/projects/UHM/

Unifying and Optimizing Data Values for Selection via Sequential Decision-Making
Hongliang Chi, Qiong Wu, Zhengyi Zhou, Jonathan Light, Emily Dodwell, Yao Ma

Data selection has emerged as a crucial downstream application of data valuation, yet the theoretical foundations for using data values in selection remain unexplored. We reformulate data selection as a sequential decision-making problem where the optimal selection sequence arises from dynamic programming, and data values can be understood as encodings of this optimal sequence. This framework unifies and reinterprets existing methods like Data Shapley through the lens of approximate dynamic programming, revealing them as myopic linear approximations to the sequential problem. We further analyze how selection optimality degrades with utility curvature under submodularity, explaining when and why these approximations fail. To bridge theory and practice, we propose an efficient bipartite graph-based surrogate that preserves submodular structure while enabling scalable greedy selection with provable guarantees. Experiments on classical ML benchmarks and large-scale LLM fine-tuning data selection demonstrate substantial improvements over existing methods. Code is publicly available at https://github.com/frankhlchi/SeqDataVal

Rank-guided Diffusion for Noise Few-Shot Learning
Zelei Wu, Kun Zhou, Xulun Ye, Yifan Mei, Jie Hong, Jieyu Zhao

In real-world Few-Shot Learning (FSL), support sets are quickly constructed and inevitably contain noisy samples. With limited examples per class, even a single noisy instance can distort class distributions, cause prototype drift, and reduce generalization. Existing methods mostly assume clean data or require large-scale statistics, which are impractical in FSL’s data-scarce setting. We find that clean samples in semantic feature space lie in low-rank subspaces, while noisy samples cause rank anomalies disrupting this structure. To address this, we propose a differentiable low-rank approximation that estimates the intrinsic rank of the support set and detects anomalous noisy samples. Building on this, a rank-guided diffusion process generates high-quality replacements under low-rank constraints, reconstructing a clean, consistent support set for improved robustness.This low-rank guided approach effectively mitigates prototype drift and significantly reduces errors under noise levels up to 40\% across MiniImageNet, TieredImageNet, and other noisy benchmarks, demonstrating the power of low-rank geometry for noise detection and correction in FSL. Our source code is available at https://github.com/wuzelei123/CRDProto.

Securing Multimodal AI through Internal Information Decomposition
Jehyeok Yeon, Hyeonjeong Ha, Qiusi Zhan, Heng Ji

Multimodal large language models introduce attack surfaces absent in unimodal systems: adversaries can distribute malicious intent across modalities to evade unimodal safeguards. This motivates using cross-modal consistency as a detection signal rather than inspecting each modality in isolation. Our key observation is that benign inputs induce compatible predictive behavior from text-only and vision-only reasoning that stabilizes when fused, whereas adversarial manipulation disrupts this consistency, causing abnormal multimodal behavior. Existing defenses that examine raw inputs or outputs overlook this internal fusion process, rendering them brittle and computationally expensive. We propose FlowGuard, a lightweight inference-time framework that detects harmful inputs by monitoring internal multimodal consistency. Unlike approaches that rely on scalar confidence metrics, FlowGuard derives FlowVectors inspired by Partial Information Decomposition that quantify cross-modal redundancy, synergy, and modality-specific dominance, capturing whether multimodal fusion aligns with unimodal semantic evidencebetween unimodal and fused multimodal output distributions. In a one-class classificat

ion problem trained solely on benign data, FlowGuard reduces Attack Success Rate s from $>90\%$ to $<15\%$ on unseen attacks, with $<3\%$ utility loss and up to a $6\times$ latency reduction. Our results demonstrate that monitoring cross-mod al consistency offers an efficient and effective defense for multimodal reasonin g.

A Statistical Framework for Analyzing Specification Resistance to Learnware-Inve rsion Risks
Hao-Yi Lei, Zhi-Hao Tan, Zhi-Hua Zhou
The learnware paradigm enables model reuse by pairing each submitted model with a specification, a public artifact used to identify helpful models without raw-d ata exchange.
This design creates a privacy surface: a useful specification must reveal capabi lity-relevant information, but such information should not expose sensitive prop erties of training data or user tasks. Is it achievable in practice? To answer t his question, this paper establishes the first framework for analyzing the incre mental risk introduced by specifications in learnware, and provides theoretical guarantees for the widely used reduced kernel mean embedding (RKME) specificatio n.
Specifically, we formulate learnware-inversion as a family of statistical decisi on games and define the risk of specification as the incremental Bayes value fro m observing the model alone to observing the complete learnware.
For the RKME specification, we derive risk bounds through an RKHS-smoothed total -variation bridge and the stability analysis of its reduced-set generator.
We further instantiate the framework for common attacks and show that a properly sized RKME specification introduces negligible additional privacy risk while re taining sufficient information for learnware identification.

An Information-Theoretic Criterion for Efficient Data Synthesis
Hanyu Li, Zhengqi Sun, Xiaotie Deng
Synthetic data becomes crucial for large language model training, but its effect iveness is highly inconsistent. We provide an information-theoretic account of t his inconsistency: synthetic data improves a model only when the generation-trai ning loop is information-open, i.e., shaped by external signals (verifiers, envi ronments, or rubrics) that inject task-relevant information beyond the model's c urrent distribution. When the loop is information-closed (relying on the model's own outputs without such signals), the data processing inequality ensures that task-relevant information can only decrease, making collapse a predicted outcome . Among information-open pipelines, both efficiency and generalization hinge on the meta-level of supervision: a coarser signal such as binary correctness treat s all acceptable outputs as equivalent, so the behavior it teaches is not tied t o any particular domain or surface form and generalizes naturally across tasks a nd domains. These observations lead to a guiding thesis: learning preferentially converges to the most information-efficient signal component available, which a ccelerates learning when that component is the intended one, but causes reward h acking when a spurious pattern happens to be simpler.
****

What Makes a Desired Graph for Relational Deep Learning?
Yao Cheng, Siqiang Luo
Relational deep learning (RDL) converts relational databases (RDBs) into heterog eneous graphs, but graphs derived directly from database schemas are often not w ell suited for how graph neural networks (GNNs) perform relational reasoning. We study what makes a relational graph suitable for deep learning and show that sc hema-derived graphs suffer from two systematic failures: information overload an d semantic fragmentation. Through an empirical analysis on real-world databases, we find that effective graphs arise from a task-dependent balance between remov ing task-irrelevant structure and injecting task-aligned relational connectivity . Filtering exhibits a non-monotonic effect on performance, while structural in jection is beneficial only when it reflects the logic of the downstream task. Ba sed on these findings, we develop an end-to-end structural optimizer that applie

s both operations to adapt relational graphs automatically. Across 23 tasks spa
nning classification, regression, and recommendation, the optimized graphs consi
stently improve accuracy while often reducing inference cost.

Unsupervised Disentanglement Without Compromises : How Functional Orthogonality
Enforces Identifiability

Mathieu Cyrille Simon, Pascal Frossard, Christophe De Vleeschouwer

This paper explores unsupervised disentangled representation learning from a fun
ctional perspective. We define latent concepts as factors that influence observa
tions through locally orthogonal directions, formalized as an orthogonality cons
traint on the Jacobian of the generative mapping. We prove that this condition y
ields identifiability of general nonlinear generative models, without requiring
statistical independence or causal assumptions, provided the latent domain admit
s all combinations of factor values. Experiments with orthogonality-regularized
normalizing flows empirically confirm the theory, demonstrate reliable recovery
of ground-truth factors, and shed light on the success of VAEs. These findings c
hallenge the prevailing impossibility claims for unsupervised disentanglement an
d provide a principled alternative foundation.

Persistent Backdoor Attacks in Class-Incremental Learning via Structural Invaria
nt Anchoring

Junhuang Huang, Linshan Hou, Jianting Ning, Yanjun Zhang, Zhongyun Hua, Leo Yu Z
hang

Continual learning (CL) involves continual parameter updates, posing a significa
nt challenge to backdoor persistence. In this paper, we reveal that the most adv
anced existing attack relies on an implicit assumption that task-critical neuron
s remain stable across task learning; however, this assumption does not hold in
class-incremental learning (CIL). This exposes a critical research gap: backdoor
 persistence in CIL remains an open question. Inspired by functional stability,
we discover that CIL models preserve task knowledge in shallow, structurally inv
ariant subspaces. Motivated by these findings, we propose PBTO, the first persis
tent and targeted backdoor attack in CIL. PBTO trains a surrogate model on proxy
 tasks to obtain a parameter trajectory. It then optimizes a universal trigger t
hat ensures misclassification to the target label across all model states and an
chors trigger embeddings in shallow layers. Experimental results verify that PBT
O maintains a high final attack success rate (ASR) across all benchmarks, while
representative baselines degrade substantially after sequential learning. Code i
s available at \href{https://github.com/hjhkkkc/PBTO}{PBTO}.

Multi-Objective Learning for Diffusion Models: A Statistical Theory under Semi-S
upervised Learning

Ziheng Cheng, Yixiao Huang, Hanlin Zhu, Haoran Geng, Somayeh Sojoudi, Jitendra M
alik, Pieter Abbeel, Xin Guo

Diffusion models are increasingly used as powerful conditional generators, yet r
eal deployments often involve multiple target distributions arising from differe
nt tasks, e.g., diverse prompt domains in text-to-image generation, or multiple
environments in robotics with diffusion policies.
This naturally leads to a multi-objective learning (MOL) problem.
A key challenge is that achieving good Pareto trade-offs can require a generalis
t model class with substantially larger capacity than what suffices for solving
any individual task, thereby increasing statistical cost since sample complexity
 typically scales with the model complexity.
To reconcile this, we develop a principled MOL framework for diffusion models wi
th limited data: a semi-supervised regime where paired (labeled) samples are sca
rce, but (unlabeled) condition data are abundant.
We propose a two-stage training procedure that first fits lightweight specialist
 models from limited paired data, and then distills them into a generalist model
 by generating pseudo-samples.
We establish generalization bounds showing that the required number of paired sa
mples only depends on the complexity of the specialist model classes.

We further extend the theory to diffusion policies for sequential decision makin
g to account for distribution shift in on-policy rollouts.
Extensive experiments on robotic control and image restoration tasks are conduct
ed to verify our theoretical results.
****

Row-Stochastic Matrices Can Provably Outperform Doubly Stochastic Matrices in De
centralized Learning
Bing Liu, Boao Kong, Limin Lu, Kun Yuan, Chengcheng Zhao
Decentralized learning often involves a weighted global loss with heterogeneous
node weights λ. We revisit two natural strategies for incorporating thes
e weights: (i) embedding them into the local losses to retain a uniform weight (
and thus a doubly stochastic matrix), and (ii) keeping the original losses while
 employing a λ-induced row-stochastic matrix. Although prior work shows
that both strategies target the same λ-weighted global loss, it remains
unclear whether the Euclidean-space guarantees are tight and what fundamentally
differentiates their behaviors. To clarify this, we develop a weighted Hilbert-s
pace framework $L^2(\lambda;\mathbb{R}^d)$ and obtain convergence rates that are
 strictly tighter than those from standard Euclidean analysis. In this geometry,
 the row-stochastic matrix becomes *self-adjoint* whereas the doubly stochastic
one does not, creating additional *penalty terms* that amplify consensus error,
thereby slowing convergence. Consequently, the difference in convergence arises
not only from spectral gaps but also from these penalty terms. We then derive su
fficient conditions under which the row-stochastic design converges faster even
with a smaller spectral gap. Finally, by using a Rayleigh-quotient and Loewner-o
rder eigenvalue comparison, we further obtain topology conditions that guarantee
 this advantage and yield practical topology-design guidelines.

Efficient and Uncertainty-Aware Diffusion Framework for Offline-to-Online Reinfo
rcement Learning
Ha Manh Bui, Metod Jazbec, Eric Nalisnick, Anqi Liu
Offline-to-Online Reinforcement Learning (O2O-RL) leverages an offline, pre-trai
ned policy to minimize costly online interactions. Although data-efficient, O2O-
RL is susceptible to shifts between offline and online distributions. Existing w
ork aims to mitigate the harm of this shift by finetuning the policy on trajecto
ry data sampled from a diffusion model. Inspired by this line of work, we propos
e DUAL: an efficient **D**iffusion **U**ncertainty-**A**ware framework for offli
ne-to-online reinforcement **L**earning. DUAL utilizes the prior knowledge of th
e diffusion model to distill a fast-sampling diffusion actor policy and transiti
on model in the offline phase. DUAL also employs a Laplace approximation and dis
tance transition-state-shift detection, thereby using uncertainty quantification
 to improve exploration versus exploitation in the online phase. We formally sho
w that our actor loss with the Laplace approximation provides a proxy for a prin
cipled estimate of epistemic uncertainty. Empirically, DUAL improves the online
expected return over O2O-RL baselines across multiple settings and environments.

Discrete Adjoint Schrödinger Bridge Sampler
Wei Guo, Yuchen Zhu, Xiaochen Du, Juno Nam, Yongxin Chen, Rafael Gomez-Bombarell
i, Guan-Horng Liu, Molei Tao, Jaemoo Choi
Learning discrete neural samplers is challenging due to the lack of gradients an
d combinatorial complexity. While stochastic optimal control (SOC) and Schröding
er bridge (SB) provide principled solutions, efficient SOC solvers like adjoint
matching (AM), which excel in continuous domains, remain unexplored for discrete
 spaces. We bridge this gap by revealing that the core mechanism of AM is *state
-space agnostic*, and introduce **discrete ASBS**, a unified framework that exte
nds AM and adjoint Schrödinger bridge sampler (ASBS) to discrete spaces. Theoret
ically, we analyze the optimality conditions of the discrete SB problem and its
connection to SOC, identifying a necessary cyclic group structure on the state s
pace to enable this extension. Empirically, discrete ASBS achieves competitive s
ample quality with significant advantages in training efficiency and scalability
. Our code is available at https://github.com/AlexandreGUO2001/DASBS.

Video-Based Optimal Transport for Feedback-Efficient Offline Preference-Based Reinforcement Learning
Tung Minh Luu, Hwanhee Kim, Younghwan Lee, Chang D. Yoo
Conveying complex objectives to reinforcement learning (RL) agents often requires meticulous reward engineering. Preference-based RL (PbRL) offers a promising alternative by learning reward functions from human feedback, but its scalability is hindered by high labeling costs. Inspired by advances in Video Foundation Models (ViFMs), we present Video-based Optimal Transport Preference (VOTP), a semi-supervised framework that learns effective reward functions from only a handful of labels. By leveraging optimal transport to align visual trajectories within the rich representation space of ViFMs, VOTP effectively generates high-fidelity pseudo-labels for large amounts of unlabeled data, substantially reducing human supervision. Extensive experiments across locomotion and manipulation benchmarks demonstrate the superiority of VOTP, which outperforms state-of-the-art offline PbRL methods under limited feedback budgets. We also showcase the robustness of VOTP in the presence of visual distractors and validate its utility on real robotic tasks, where it learns meaningful rewards with minimal human input.
****
DREAM: A Unified Framework for Drift-Corrected Federated Multi-Objective Learning
Yuan Zhou, Yidan Ou, Xinli Shi
Federated Multi-Objective Learning (FMOL) enables collaborative training of conflicting objectives but faces a compounded challenge: the recursive coupling between intra-task client drift and inter-task aggregation bias.
We propose DREAM, a unified framework that jointly corrects these two coupled error sources through drift-aware control variates and momentum-smoothed local updates.
On the server side, DREAM formulates multi-objective aggregation as a regularized quadratic program parameterized by a task correction matrix, which provides a generalized formulation that can flexibly adapt to scalarization, prioritization, and gradient manipulation strategies.
Theoretically, we establish a linear speedup convergence rate of $\mathcal{O}(1/\sqrt{NT})$ for non-convex objectives.
We further provide theoretical guarantees for the conflict-avoidant direction distance.
In the strongly convex setting, DREAM achieves convergence in weighted sub-optimality and admits a unified Lyapunov analysis showing linear convergence to a regularization-dependent neighborhood.
Numerical experiments on representative benchmarks validate the effectiveness of DREAM in multi-objective optimization.

FLARE-AI: Flaw Reporting for AI
Shayne Longpre, Elaine Zhu, Carson Ezell, Avijit Ghosh, Sean McGregor, Kevin Paeth, Kevin Klyman, Sayash Kapoor, Rishi Bommasani, Ruth E. Appel, Gregory Strom, Lauren McIlvenny, Mark M. Jaycox, Peter Slattery, Nathan Butters, Arvind Narayanan, Percy Liang, Alex Pentland
Flaw reporting for deployed AI systems is fundamental to identifying system failures and improving AI safety. Yet the AI reporting ecosystem is fragmented: researchers who identify flaws often do not know what or where to report, and groups who receive reports rarely share them with other relevant stakeholders. As a result, good-faith reporters duplicate effort by submitting many different forms, and recipients lack standardized, triage-ready information. We survey 12 reporting systems published by AI developers, cybersecurity groups, and AI flaw aggregators, identifying five recurring design challenges spanning discoverability, scope, information collection, coordination, and guidance for strict-liability cases. Building on this analysis and feedback from 49 experts across 32 organizations representing developers, security researchers, and ecosystem coordinators, we introduce FLARE-AI, an open-source AI flaw reporting system designed for interoperability with existing systems. FLARE-AI streamlines flaw report creation by co

llecting triage-relevant information through conditional logic and early classif ication, then enables optional dissemination of standardized, machine-readable r eports to multiple developers, coordinators, and incident registries from a sing le submission. By lowering barriers to reporting AI flaws and improving interope rability across stakeholders, FLARE-AI helps break down silos and accelerate rem ediation across the AI ecosystem.

Accelerated and Stable Convergence with Anchored Generalized Optimistic Method
Motahareh Sohrabi, Jianxin You, Simon Lacoste-Julien, Eduard Gorbunov, Gauthier Gidel
We study first-order methods for solving monotone variational inequalities arisi ng in min-max optimization. Classical approaches such as the extragradient metho d rely on two gradient queries per iteration, which limits their analysis and ap plicability in the online and stochastic settings. We propose a family of Genera lized Optimistic Methods with Anchoring (GOMA), which combine two-time-scale opt imistic updates with an anchoring term inspired by Halpern iteration. In the det erministic setting, GOMA achieves the optimal accelerated last-iterate rate $\ma thcal{O}(1/k^2)$ on the squared gradient norm for monotone Lipschitz operators. In the stochastic setting with unbounded variance, a simplified single-call vari ant of GOMA achieves a last-iterate convergence rate of $\mathcal{O}(1/\sqrt{k}) $ on the squared gradient norm. To the best of our knowledge, this is the first such guarantee for stochastic monotone Lipschitz VIs in the unconstrained settin g without variance reduction or growing batches.

Training-Trajectory-Aware Token Selection
Zhanming Shen, Jiaqi Hu, Zeyu Qin, Hao Chen, Wentao Ye, Zenan Huang, yihong zhua ng, Guoshan Lu, Junlin Zhou, Junbo Zhao
Efficient distillation is a key pathway for converting expensive reasoning capab ility into deployable efficiency, yet in the frontier regime where the student a lready has strong reasoning ability, naive continual distillation often yields l imited gains or even degradation. We observe a characteristic training phenomeno n: even as loss decreases monotonically, all performance metrics can drop sharpl y at almost the same bottle-neck, before gradually recovering. We further uncove r a token-level mechanism: confidence bifurcates into steadily increasing Imitat ion-Anchor Tokens that quickly anchor optimization and other yet-to-learn tokens whose confidence is suppressed until after the bottleneck. And the characterist ic that these two types of tokens cannot coexist is the root cause of the failur e in continual distillation. To this end, we propose Training-Trajectory-Aware T oken Selection (T3S) to reconstruct the training objective at the token level, c learing the optimization path for yet-to-learn tokens. T3S yields consistent gai ns in both AR and dLLM settings: with only hundreds of examples, Qwen3-8B surpas ses DeepSeek-R1 on competitive reasoning benchmarks, Qwen3-32B approaches Qwen3- 235B, and T3-trained LLaDA-2.0-Mini exceeds its AR baseline, achieving state-of- the-art performance among all of 16B-scale no-think models.
****

GTPO and GRPO-S: Token and Sequence-Level Reward Shaping with Policy Entropy
Hongze Tan, Zihan Wang, Jianfei Pan, Jinghao Lin, Hao Wang, Yifan Wu, Tao Chen, Zhihang Zheng, Zhihao Tang, Haihua Yang
Reinforcement Learning (RL) is pivotal for enhancing Large Language Model (LLM) reasoning, yet mainstream algorithms such as GRPO and DAPO remain constrained by a coarse-grained credit assignment paradigm, where all tokens within the same r esponse receive the identical reward. In this paper, we propose **Dynamic Entrop y Weighting**, systematically define entropy-based weight ratios $\frac{H_{i,t}} {\sum_{k=1}^{n} H_{k,t}}$ and similar variants to redistribute rewards and get f ine-grained rewards through two new algorithms: **Group Token Policy Optimizatio n (GTPO)**, which assigns an entropy-weighted reward to each token and synthesiz es token-specific advantage function to drive the model toward optimal path, and the analogous algorithm **Sequence-Level GRPO (GRPO-S)**, which admits a comple tely similar design at the sequence level. Unlike methods using entropy as mere regularization, GTPO and GRPO-S establish a new state-of-the-art on AIME and MAT

H 500, outperforming prior entropy-guided baselines and validating our weighting mechanism.

DGS-Net: Distillation-Guided Gradient Surgery for CLIP Fine-Tuning in AI-Generated Image Detection

Jiazhen Yan, Ziqiang Li, Fan Wang, Boyu Wang, Ziwen He, Zhangjie Fu

The rapid progress of generative models such as GANs and diffusion models has led to the widespread proliferation of AI-generated images, raising concerns about misinformation, privacy violations, and trust erosion in digital media. Although large-scale multimodal models like CLIP offer strong transferable representations for detecting synthetic content, fine-tuning them often induces catastrophic forgetting, which degrades pre-trained priors and limits cross-domain generalization. To address this issue, we propose the Distillation-guided Gradient Surgery Network (DGS-Net), a novel framework that preserves transferable pre-trained priors while suppressing task-irrelevant components. Specifically, we introduce a gradient-space decomposition that separates harmful and beneficial descent directions during optimization. By projecting task gradients onto the orthogonal complement of harmful directions and aligning with beneficial ones distilled from a frozen CLIP encoder, DGS-Net achieves unified optimization of prior preservation and irrelevant suppression. Extensive experiments on 50 generative models demonstrate that our method outperforms state-of-the-art approaches by an average margin of 6.6%, achieving superior detection performance and generalization across diverse generation techniques.

Optimal Regularization for Performative Learning

Edwige Cyffers, Alireza Mirrokni, Marco Mondelli

In performative learning, the data distribution reacts to the deployed model—for example, because strategic users adapt their features to game it—which creates a more complex dynamic than in classical supervised learning. One should thus not only optimize the model for the current data but also take into account that the model might steer the distribution in a new direction, without knowing the exact nature of the potential shift. We explore how regularization can help cope with performative effects by studying its impact in high-dimensional ridge regression.

We show that, while performative effects worsen the test risk in the population setting, when moving to the over-parameterized regime where the number of features exceeds the number of samples, the optimal regularization in the presence of performativity helps reduce the variance in the estimated parameters, thereby improving performance. We show that the optimal regularization scales with the overall strength of the performative effect, making it possible to set the regularization in anticipation of this effect. We illustrate this finding through empirical evaluations of the optimal regularization parameter on both synthetic and real-world datasets.

Scalable and Interpretable Representation Alignment with Ordinal Similarity

Diogo Soares, Pankhil Gawade, Andrea Dittadi, Ewa Szczurek

Evaluating representation similarity is fundamental to representation learning. However, existing metrics suffer from significant limitations: they lack interpretability due to shifting baselines, lack robustness to outliers, and are computationally intractable for large datasets, forcing reliance on heuristic approximations. To address this, we develop an ordinal-similarity framework, instantiated by the Triplet (TSI) and Quadruplet (QSI) Similarity Indices, which measure alignment by quantifying the consistency of ordinal relationships. We theoretically demonstrate this formulation is inherently interpretable, robust to outliers, and computationally efficient. Finally, we establish a formal equivalence between TSI and local neighborhood alignment, measured by Mutual Nearest Neighbors. Empirically, we validate these properties and show that ordinal similarity offers a scalable approach to measuring alignment, enabling practitioners to better understand and design representations.
****

The Label Horizon Paradox: Rethinking Supervision Targets in Financial Forecasting

Chen-Hui Song, Shuoling Liu, Liyuan Chen

While deep learning has revolutionized financial forecasting through sophisticated architectures, the design of the supervision signal itself is rarely scrutinized. We challenge the canonical assumption that training labels must strictly mirror inference targets, uncovering the Label Horizon Paradox: the optimal supervision signal often deviates from the prediction goal, shifting across intermediate horizons governed by market dynamics. We theoretically ground this phenomenon in a dynamic signal-noise trade-off, demonstrating that generalization hinges on the competition between marginal signal realization and noise accumulation. To operationalize this insight, we propose a bi-level optimization framework that autonomously identifies the optimal proxy label within a single training run. Extensive experiments on large-scale financial datasets demonstrate consistent improvements over conventional baselines, thereby opening new avenues for label-centric research in financial forecasting.

Can Agents Generalize to the Open World? Unveiling the Fragility of Static Training in Tool Use

Weiming Wu, Song-Lin Lv, Rui Zhu, Zi-Jian Cheng, Lan-Zhe Guo

While Large Language Model (LLM) agents demonstrate proficiency in static benchmarks, their deployment in real-world scenarios is hindered by the dynamic nature of user queries, tool sets, and interaction dynamics.To address this generalization gap, we formalize **OpenAgent** (Tool-Use Agent in Open-World), a problem setting characterized by distributional shifts across query, action, observation, and domain dimensions.To systematically diagnose its impact, we construct a controlled sandbox environment where we define fine-grained environmental shifts across a four-tier hierarchy, *Perception*, *Interaction*, *Reasoning*, and *Internalization*, and conduct a comprehensive series of experiments. Our analysis yields a series of key insights, demonstrating that agents trained via both Supervised Fine-Tuning (SFT) and Reinforcement Learning suffer from varying degrees of performance degradation when confronting open environmental shifts.Building on these insights, we propose Perturbation-Augmented Fine-Tuning, a disturbance-based intervention strategy for SFT that lays the foundation for enhancing agent robustness and utility in realistic environments. Our code will be released at: https://github.com/LAMDA-NeSy/OpenAgent.

Transport or Discard: Robust Unbalanced Optimal Transport for Cross-Domain Policy Adaptation

Wenyu Chen, Yujia Zhang, Wei Guo, Linli Ma, Yanbo Wang, Pinle Qin, Jianchao Zeng

Cross-domain offline reinforcement learning leverages a source dataset to improve policy learning in a data-scarce target domain, but dynamics mismatch makes many source transitions kinematically infeasible and can cause negative transfer. Recent non-parametric geometric methods (e.g., standard optimal transport and k-nearest neighbors) avoid overfitting yet often yield only relative rankings under an implicit matching or retrieval budget, making performance sensitive to hand-tuned thresholds when the true cross-domain overlap is unknown. We formulate availability estimation as soft subset selection by learning a source reweighting that geometrically aligns with the target. We propose **R**obust **O**ffline unbalanced **O**ptimal **T**ransport (ROOT): (i) a robust ambiguity set for uncertainty under limited target samples, and (ii) an unbalanced transport objective that penalizes mass deviation, enabling a principled transport-or-discard mechanism. ROOT thus down-weights or discards high-cost source samples rather than forcing them onto the target support. Moreover, the induced weights decay exponentially with transport cost, guaranteeing outlier suppression. On D4RL dynamics-shift benchmarks, ROOT improves downstream offline RL and outperforms strong baselines on most tasks without task-specific threshold tuning.

HyPER: Bridging Exploration and Exploitation for Scalable LLM Reasoning with Hypothesis Path Expansion and Reduction

Shengxuan Qiu, Haochen Huang, Shuzhang Zhong, Pengfei Zuo, Meng Li
Scaling test-time compute with multi-path chain-of-thought can improve reasoning accuracy, but its gains hinge on an effective exploration–exploitation trade-off. Existing methods handle this trade-off in rigid ways: tree-structured search hard-codes exploration via brittle expansion rules that disrupt post-trained reasoning, while parallel reasoning over-explores redundant hypothesis paths and relies on a weak answer selection strategy. Driven by the insight that the optimal balance is *phase-dependent* and that correct vs. incorrect paths often *diverge only at late stages*, we reconceptualize test-time scaling as a dynamic *expand–reduce* control problem over a pool of hypothesis paths. We introduce **HyPER**, a *training-free online control policy* for MoE multi-path decoding that reallocates compute under a fixed budget using lightweight path statistics. HyPER features (i) an *online controller* that shifts from exploration to exploitation as the hypothesis pool evolves, (ii) an MoE-based token-level refinement primitive for efficient *generation-time exploitation* without full-path resampling, and (iii) a length- and confidence-aware aggregation rule to bridge the existence–selection gap for reliable *answer-time exploitation*. Extensive experimental results across four MoE models and diverse benchmarks demonstrate HyPER consistently achieves the accuracy–compute Pareto frontier, outperforming prior-art methods by 8-10% while reducing token consumption by 25-40%.

Multicalibration Yields Better Matchings
Riccardo Colini Baldeschi, Simone Di Gregorio, Simone Fioravanti, Federico Fusco, Ido Guy, Daniel Haimovich, Stefano Leonardi, Fridolin Linder, Lorenzo Perini, Matteo Russo, Cem Sirin, Niek Tax
Consider the problem of finding the best matching in a weighted graph where we only have access to predictions of the actual stochastic weights, based on an underlying context. If the predictor is the Bayes optimal one, then computing the best matching based on the predicted weights is optimal. However, in practice, this perfect information scenario is not realistic. Given an imperfect predictor, a suboptimal decision rule may compensate for the induced error and thus outperform the standard optimal rule.
In this paper, we propose multicalibration as a way to address this problem. This fairness notion requires a predictor to be unbiased on each element of a family of protected sets of contexts. Given a class of matching algorithms $\mathcal C$ and any predictor γ of the edge-weights, we show how to construct a specific multicalibrated predictor $\hat \gamma$, with the following property. Picking the best matching based on the output of $\hat \gamma$ is competitive with the best decision rule in $\mathcal C$ applied onto the original predictor γ. We complement this result by providing sample complexity bounds, and by performing numerical experiments.

Learnable Kernel Density Estimation for Graphs and Its Application to Graph-Level Anomaly Detection
Xudong Wang, Ziheng Sun, Chris Ding, Jicong Fan
This work proposes a framework LGKDE that learns kernel density estimation for graphs. The key challenge in graph density estimation lies in effectively capturing both structural patterns and semantic variations while maintaining theoretical guarantees. Combining graph kernels and kernel density estimation (KDE) is a standard approach to graph density estimation, but has unsatisfactory performance due to the handcrafted and fixed features of kernels. Our method LGKDE leverages graph neural networks to represent each graph as a discrete distribution and utilizes maximum mean discrepancy to learn the graph metric for multi-scale KDE, where all parameters are learned by maximizing the density of graphs relative to the density of their well-designed perturbed counterparts. The perturbations are conducted on both node features and graph spectra, which helps better characterize the boundary of normal density regions. Theoretically, we establish consistency and convergence guarantees for LGKDE, including bounds on the mean integrated squared error, robustness, and generalization. We validate LGKDE by demonstrating its effectiveness in recovering the underlying density of synthetic graph d

istributions and applying it to graph anomaly detection across diverse benchmark datasets. Extensive empirical evaluation shows that LGKDE demonstrates superior performance compared to state-of-the-art baselines on most benchmark datasets.
****
VIP: Visual-guided Prompt Evolution for Efficient Dense Vision-Language Inferenc
e
Hao Zhu, Shuo Jin, Wenbin Liao, Jiayu Xiao, Yan Zhu, Siyue Yu, Feng Dai
Pursuing training-free open-vocabulary semantic segmentation in an efficient and generalizable manner remains challenging due to the deep-seated spatial bias in CLIP.
To overcome the limitations of existing solutions, this work moves beyond the CL
IP-based paradigm and harnesses the recent spatially-aware dino.txt framework to facilitate more efficient and high-quality dense prediction.
While dino.txt exhibits robust spatial awareness, we find that the semantic ambi
guity of text queries gives rise to severe mismatch within its dense cross-modal interactions.
To address this, we introduce VIsual-guided Prompt evolution (VIP) to rectify th
e semantic expressiveness of text queries in dino.txt, unleashing its potential for fine-grained object perception.
Towards this end, VIP integrates alias expansion with a visual-guided distillati
on mechanism to mine valuable semantic cues, which are robustly aggregated in a saliency-aware manner to yield a high-fidelity prediction.
Extensive evaluations demonstrate that VIP: I) surpasses the top-leading methods by 1.4%~8.4\% average mIoU, II) generalizes well to diverse challenging domains
, and III) requires marginal inference time and memory overhead.
****
EAGer: Entropy-Aware GEneRation for Adaptive Inference-Time Scaling
Daniel Scalena, Leonidas Zotos, Elisabetta Fersini, Malvina Nissim, Ahmet Üstün
With the rise of reasoning language models and test-time scaling methods as a pa
radigm for improving model performance, substantial computation is often require
d to generate multiple candidate sequences from the same prompt. This enables ex
ploration of different reasoning paths toward the correct solution, however, all
ocates the same compute budget for each prompt. Grounded on the assumption that
different prompts carry different degrees of complexity, and thus different comp
utation needs, we propose EAGer, a training-free generation method that leverage
s model uncertainty through token-wise entropy distribution to reduce redundant
computation and concurrently improve overall performance. EAGer allows branching to multiple reasoning paths only in the presence of high-entropy tokens, and re
allocates the saved compute budget to instances where exploration of alternative paths is most needed. We validate EAGer across multiple open-source models on c
omplex reasoning benchmarks, with gains specifically demonstrated on AIME 2025.
When target labels are accessible -- as in RLVR training pipelines -- EAGer achi
eves up to +37% in Pass@k and 59% fewer tokens; in test-time settings it still y
ields +12% in Pass@k and 64% fewer tokens compared to Full Parallel Sampling.

Multi-timescale Reinforcement Learning by Value Reconstruction
Zhan Su, Peixi Peng, Xinyu Hu, Cong Li, Yisen Zhao, Zhuojian Li, Yonghong Tian,
Fanqi Shen
Most reinforcement learning (RL) baselines maximize future cumulative rewards wi
th a fixed single discount factor, which
limits their performance in complex sequential decision-making tasks due to a fa
ilure to balance short-term objectives and
long-term planning. To address this issue, this paper focuses on a multi-timesca
le critic framework, where each component corresponds
to a Q-value with a distinct discount factor. Two key improvements are proposed: (1) A Neural Reward Decoder reconstructs the
reward sequence from multi-scale Q-values, with value and reward reconstruction
losses enhancing Q-value estimation consistency;
(2) A cross-attention-based Q-weight predictor adaptively adjusts Q-value weight
s via current observations to generate the final

Q-value for policy optimization. Extensive experiments on DMControl and CARLA be
nchmarks demonstrate that our method
significantly outperforms state-of-the-art (SOTA) baselines. Furthermore, we val
idate the framework's generalizability
by integrating it with both off-policy (SAC, DrQ-v2) and on-policy (PPO) algorit
hms, achieving consistent performance gains.
The code is available in the supplementary material.

Human-AI Collaborative Uncertainty Quantification
Sima Noorani, Shayan Kiyani, George J. Pappas, Hamed Hassani
AI predictive systems increasingly support high-stakes decision making, yet robu
st decisions under uncertainty often rely on human capabilities beyond AI alone.
 This motivates collaborative approaches that combine human judgment with AI pre
dictions. We study this problem through the lens of uncertainty quantification a
nd introduce **Human-AI Collaborative Uncertainty Quantification**, a framework
in which an AI system refines a human expert’s proposed prediction set subject t
o two principles: **counterfactual harm**, requiring that the AI not degrade cor
rect human judgments, and **complementarity**, requiring recovery of correct out
comes the human missed. At the population level, we show that the optimal collab
orative prediction set has a simple two-threshold structure over a single score
function, governing pruning and augmentation relative to the human proposal. Bui
lding on this characterization, we develop offline and online calibration algori
thms with **distribution-free** finite-sample guarantees. The online algorithm a
dapts to arbitrary distribution shifts, including settings where human behavior
evolves through interaction with the AI. Empirically, we show that collaborative
 prediction sets outperform human-only and AI-only baselines, achieving improved
 coverage--efficiency tradeoffs across image classification, regression, and tex
t-based medical decision making.

A Theory of Data Acquisition and Pricing at Scale
Andrew Ilyas, Amin Saberi, Grigoris Velegkas
Data plays an invaluable role in large-scale ML training pipelines. Multiple fac
tors, including the need to incentivize the creation of high-quality data and ef
forts to compensate creative data work, have led to increased interest in data p
ricing.
Data pricing mechanisms seek to establish a market where data providers are comp
ensated based (in part) on the value of their data to the data buyer, e.g., fron
tier AI labs. However, assessing the exact value that each provider's data adds
to the data buyer's objective requires repeated re-training, which is infeasible
 in practice.
Our work studies data pricing under compute constraints.
In our setting, data buyers cannot make data acquisition decisions optimally due
 to limited compute.
Inspired by existing practice in the field of data selection, we propose a model
 for this problem called ``pricing with an attribution oracle,'' and provide a t
heoretical analysis of compute-efficient acquisition and pricing.

Acoustic Interference: A New Paradigm Weaponizing Acoustic Latent Semantic for U
niversal Jailbreak against Large Audio Language Models
Yanyun Wang, Yu Huang, Zi Liang, Xixin Wu, Li Liu
The integration of audio modality into Large Audio Language Models (LALMs) signi
ficantly expands their attack surface. Existing jailbreaks predominantly treat a
udio as a carrier for malicious payloads, relying on semantic optimization, acou
stic parameter control, or additive perturbation to embed harmful content into t
he audio signal. In this work, we challenge this necessity and propose a new par
adigm in which the role of audio shifts from content injection to safety alignme
nt interference. We reveal that LALM safety alignment can be compromised solely
by specific **Acoustic Latent Semantics (ALS)**, the underlying paralinguistic f
eatures intrinsic to the priors of audio generative models. Distinct from previo
us works that leverage explicit acoustic parameters to merely style malicious au

dio, we demonstrate that interference audio, benign in content but infused with specific ALS, can serve as a universal jailbreak trigger. Leveraging this insight, we propose **Acoustic Interference Attack (AIA)**, which decouples the attack payload from the audio. It employs a set of universal, instruction-neutral interference audio, enabling standard malicious text queries to bypass safety alignment without instance-specific optimization. Experiments on 10 LALMs across five datasets demonstrate that AIA achieves the state-of-the-art attack success rate. Furthermore, our interpretability analysis uncovers the inference path drift induced by AIA and identifies the inherent effective patterns within ALS, revealing the fundamental vulnerability of cross-modal alignment in LALMs.

SURF: Separation via Unsupervised Remixing Flow

Henry Li, Robin Scheibler, Efthymios Tzinis, Matt Shannon, Arnaud Doucet, John R. Hershey

The goal of single-channel source separation is to reconstruct K sources given their mixture. In supervised settings where vast amounts of clean source data are available, this challenging, ill-posed problem has been addressed successfully by generative diffusion and flow-based prior models. However, access to such clean source samples is often limited, and even when available, supervised models are vulnerable to domain shifts. To bridge this gap, we present Separation via Unsupervised Remixing Flow (\textbf{SURF}), an unsupervised flow matching approach for source separation that learns directly from observed mixtures. This method relies on a novel combination of state-of-the-art supervised flow matching and regression-based self-supervised techniques. At a high level, starting from a teacher model, we utilize a ``remixing'' step to bootstrap the learning of a student flow model from the teacher's estimates. We provide insights into the objectives optimized by this approach and draw a novel connection to the Wake-Sleep algorithm. Empirical evaluations on image and audio benchmarks demonstrate that \textbf{SURF} establishes a new state-of-the-art, significantly outperforming existing unsupervised methods. See our demo page for examples. https://google.github.io/df-conformer/surf/

Learning Self-Correction in Vision–Language Models via Rollout Augmentation

Yi Ding, Ziliang Qiu, Bolian Li, Ruqi Zhang

Self-correction is essential for solving complex reasoning problems in vision–language models (VLMs), yet existing reinforcement learning (RL) methods struggle to learn it.

Effective self-correction behaviors emerge only rarely during RL, making learning signals sparse. To address this challenge, we propose c**o**rre**ct**i**o**n-s**p**ecific rollo**u**t**s**} (**Octopus**), a rollout-augmentation framework that synthesizes dense self-correction supervision by recombining existing rollouts without computational overhead. This rollout augmentation simultaneously improves sample efficiency and stabilizes RL optimization. Furthermore, we introduce a two-stage RL training strategy that disentangles self-correction and direct reasoning, avoiding signal conflicts and enabling both behaviors to be learned effectively.

Building on this, we introduce $\texttt{Octopus-8B}$, an advanced reasoning VLM with controllable self-correction capabilities. It achieves SoTA performance among open-source VLMs across 7 benchmarks, outperforming the best RLVR baseline by 1.0 score while requiring only $0.72\times$ training time per step.

****

Hyperspectral Image Fusion with Spectral-Band and Fusion-Scale Agnosticism

Yujie Liang, Zihan Cao, Liang-Jian Deng, Yang Yang, Malu Zhang

Current deep learning models for Multispectral and Hyperspectral Image Fusion (MS/HS fusion) are typically designed for fixed spectral bands and spatial scales, which limits their transferability across diverse sensors. To address this, we propose SSA, a unified framework for MS/HS fusion with spectral-band and fusion-scale agnosticism. Specifically, we introduce Matryoshka Kernel (MK), a novel operator that enables a single model to process varying ordered spectral band counts within a supported range. Meanwhile, we build SSA upon an Implicit Neural Rep

resentation (INR) backbone that models the HS signal as a continuous function, e nabling reconstruction at arbitrary spatial resolutions. Together, these two mec hanisms support a single MS/HS fusion model for heterogeneous sensors and arbitr ary query scales. Extensive experiments demonstrate that our single jointly trai ned model achieves state-of-the-art performance, generalizes to unseen spatial s cales, and transfers to unseen sensors with few-step adaptation. The code can b e obtained at https://github.com/vg219/SSA.

DreamDojo: A Generalist Robot World Model from Large-Scale Human Videos
Shenyuan Gao, William Liang, Kaiyuan Zheng, Ayaan Naveed Malik, Seonghyeon Ye, S ihyun Yu, Wei-Cheng Tseng, Yuzhu Dong, Kaichun Mo, Chen-Hsuan Lin, Jiannan Xiang , Yuqi Xie, Ruijie Zheng, Dantong Niu, Pooya Jannaty, Jinwei Gu, Jun Zhang, Jite ndra Malik, Pieter Abbeel, Ming-Yu Liu, Yuke Zhu, Joel Jang, Linxi Fan
Being able to simulate the outcomes of actions in varied environments will revol utionize the development of generalist agents at scale. However, modeling these world dynamics, especially for dexterous robotics tasks, poses significant chall enges due to limited data coverage and scarce action labels. As an endeavor towa rds this end, we introduce DreamDojo, a foundation world model that learns diver se interactions and dexterous controls from 44k hours of egocentric human videos . Our data mixture represents the largest video dataset to date for world model pretraining, spanning a wide range of daily scenarios with diverse objects and s kills. To address the scarcity of action labels, we introduce continuous latent actions as unified proxy actions, enhancing interaction knowledge transfer from unlabeled videos. After post-training on small-scale target robot data, DreamDoj o demonstrates a strong understanding of physics and precise action controllabil ity. We also devise a distillation pipeline that accelerates DreamDojo to a real -time speed of 10.93 FPS and further improves consistency to the context. Our wo rk enables several important applications based on generative world models, incl uding live teleoperation, policy evaluation, and model-based planning. Systemati c evaluation on multiple challenging out-of-distribution (OOD) benchmarks verifi es the significance of our method for simulating open-world, contact-rich tasks, paving the way for general-purpose robot world models.

Active Regression for Single-Index Models with Unknown Link Functions
Chansophea Wathanak In, Yi Li, Wai Ming Tai, Xuan Wu
This paper studies active regression for single-index models under general $\ell _p$-loss with an unknown 1-Lipschitz link function f, formulated as $\min_{f ,x} \Vert f(Ax)-b\Vert_p^p$ with full access to A but coordinate-query access to b.
Prior work established upper bounds for known link functions for all $p\geq 1$ a nd for unknown link functions only in the $p=2$ case, together with lower bounds for $p\leq 2$.
This work addresses the more challenging setting of unknown link functions and g eneral $p \geq 1$.
A non-adaptive sampling algorithm is presented that achieves a $(1+\epsilon)$-ap proximation using $O(d^{p/2\vee 1}/\epsilon^{p\vee 2}\text{poly}\log(n/\epsilon))$ queries. Nearly tight lower bounds are also established for non-adaptive quer ies when $p>2$. These results close much of the remaining gap in active ℓ_p regression for single-index models.
****
RGMem: Renormalization Group–inspired Memory Evolution for Language Agents
Ao Tian, Yunfeng Lu, Xinxin Fan, Changhao Wang, Lanzhi Zhou, Yeyao Zhang, Yanfan g Liu
Personalized and continuous interactions are critical for LLM-based conversation al agents, yet finite context windows and static parametric memory hinder the mo deling of long-term, cross-session user states. Existing approaches, including r etrieval-augmented generation and explicit memory systems, primarily operate at the fact level, making it difficult to distill stable preferences and deep user traits from evolving and potentially conflicting dialogues.To address this chall enge, we propose RGMem, a self-evolving memory framework inspired by the renorma

lization group (RG) perspective on multi-scale organization and emergence. RGMem models long-term conversational memory as a multi-scale evolutionary process: episodic interactions are transformed into semantic facts and user insights, which are then progressively integrated through hierarchical coarse-graining, thresholded updates, and rescaling into a dynamically evolving user profile.By explicitly separating fast-changing evidence from slow-varying traits and enabling nonlinear, phase-transition-like dynamics, RGMem enables robust personalization beyond flat retrieval or static summarization. Extensive experiments on the LOCOMO and PersonaMem benchmarks demonstrate that RGMem consistently outperforms SOTA memory systems, achieving stronger cross-session continuity and improved adaptation to evolving user preferences.

Convex Basins in Single-Index Model Loss Landscapes: Applications to Robust Recovery under Strong Adversarial Corruption

SANTANU DAS, Sagnik Chatterjee, jatin batra

In this paper, we tackle a fundamental problem in high-dimensional statistics, namely, learning Single Index Models (SIMs) robustly in the presence of heavy-tailed noise and an adversary that can corrupt a constant fraction of both covariates and responses. Prior research on efficient robust recovery only focuses on monotonic link functions or only limit themselves to Phase Retrieval. Provable efficient robust recovery guarantees for generic nonlinear link functions have remained elusive. In this paper, we obtain the first near-linear time, optimal-sample-complexity robust recovery algorithm for a wide class of nonlinear non-monotonic link functions. Critical to our result is an improved understanding of the squared-loss landscape: we identify a sufficient condition under which a broad class of non linear link functions admit a dimension-independent constant-radius convex basin around the ground truth, establishing statistical identifiability beyond previously known cases. We also leverage second-order Stein's identities to identify a structural condition, that we term Expected Squared Convexity (ESC), that acts as a sufficient condition for spectral initialization techniques to obtain an estimator within the convex basin with error $O(\epsilon^{1/4})$, even under heavy-tailed noise and strong adversarial contamination. This robust initialization technique can be combined with a robust gradient descent phase to break the spectral error barrier, achieving an improved estimation error of $O(\sigma\sqrt{\epsilon})$. Our non-convex optimization framework gives the first efficient sample and time complexity robust recovery results for activation functions such as GeLU and Swish that act as building blocks of modern deep-learning architectures.

Understanding SAM through Minimax Perspective

Ying Chen, Aoxi Li, Javad Lavaei

Sharpness-Aware Minimization (SAM) empirically boosts generalization by seeking parameters that minimize the worst-case loss in a small neighborhood, yet existing theory explains its behavior under either Polyak-Lojasiewicz (PL) condition or upper bounded perturbation radius. We revisit SAM through the bilevel minimax problem $\min_{\theta}\max_{\|\Delta\|\le\rho}l(\theta+\Delta)$ and derive a (θ,Δ) gradient flow ODE whose equilibria coincide with the problem’s optimality conditions. A Lyapunov argument-free of convexity assumptions, quantifies how the optimality gap depends on the radius~ρ and local curvature. Discretizing the flow yields a \emph{Multi-step SAM} algorithm that recovers classical SAM as $\rho\to 0$. Moreover, our analysis and the resulting algorithm remain valid even for large ρ, providing guidance for aggressive neighborhood exploration. Experiments on synthetic objectives and CIFAR-10 validate the predicted gains from multiple inner updates, bridging the gap between SAM’s minimax intuition and its practical implementation.

EvoCF: Multi-Agent Collaboration via Agentic Memory-Driven Evolutionary Counterfactual Planning

Haotian Chi, Zeyu Feng, Xingrui Yu, Linbo Luo, Yew-Soon Ong, Ivor Tsang, Hechang Chen, Yi Chang, Haiyan Yin

Planning collaboration strategies for multi-agent embodied systems remains a cor
e challenge for LLM-based planners, which often fail to capture the physical and
 coordination constraints of realworld environments. To address this, we present
 EvoCF, an agentic memory-driven evolutionary counterfactual planning framework
for discovering improved multi-agent collaboration strategies through counterfac
tual plan generation and evaluation. First, we propose a symbolic constraint ind
uctor that induces reusable symbolic constraints from failures, forming an evolv
ing rule library. Then, we propose an evolutionary counterfactual plan generator
 that systematically explores semantically consistent plan variants through rule
-conditioned mutations, enabling robust collaboration strategies beyond short-si
ghted one-shot LLM plans. Finally, we design an agentic memory-grounded evaluato
r that ranks candidate plans using retrieval-augmented evidence, producing inter
pretable, constraint-aware selections. Across multi-agent embodied simulation be
nchmarks, EvoCF consistently discovers more robust and executable plans compared
 to baseline approaches. Our results demonstrate that grounding multi-agent plan
ning in agentic memory and counterfactual reasoning significantly enhances both
effectiveness and robustness.

IEC: When Information-Driven Exploration Meets Spectral Consensus via Primal–Dua
l Reward Regularization in Decentralized Multi-Agent RL

Xuefeng Du, Jiajun Wu, Yuduo Zheng, Fengqi Li

Decentralized multi-agent reinforcement learning faces a persistent exploration
–coordination tension: intrinsic rewards promote exploration under sparse feedba
ck, yet effective cooperation requires agents’ behaviors to remain consistent ov
er a limited communication graph. Existing methods often combine exploration bon
uses and coordination regularizers with fixed-weight schedules, making them hard
 to tune and prone to either fragmented conventions or premature behavioral coll
apse. We propose the IEC (Isomorphic Exploration-Consensus) framework that coupl
es exploration and coordination through a single constrained objective: maximize
 task return augmented with two complementary exploration signals, dynamics-base
d information gain and state-coverage novelty, while constraining graph-induced
policy disagreement via a spectral smoothness penalty on neighboring agents, whi
ch can be interpreted as a Dirichlet-energy regularizer on the communication gra
ph. IEC optimizes the resulting Lagrangian with a lightweight primal–dual update
 that adapts the consensus multiplier from observed constraint violations, yield
ing an automatic shift from diverse exploration to stable cooperative convention
s. Across three distinct benchmarks, IEC achieves superior performance.

SpatialJB: How Text Distribution Art Becomes The "Jailbreak Key" for LLM Guardra
ils

Zhiyi Mou, Jingyuan Yang, ZEHENG QIAN, Wangze Ni, Tianfang Xiao, Ning Liu, Chen
Jason Zhang, Zhan Qin, Kui Ren

While Large Language Models (LLMs) have achieved remarkable success across diver
se tasks, they remain vulnerable to jailbreak attacks, which pose significant ri
sks to their secure deployment. Driven by their inherent token-by-token autoregr
essive inference, LLMs exhibit semantic representations that lack robustness aga
inst spatially structured perturbations, thereby rendering current output-guardr
ail safety mechanisms penetrable.

Exploiting the Transformer's spatial weakness, we propose SpatialJB to disrupt t
he model’s output generation process, allowing harmful content to bypass guardra
ils without detection. Comprehensive experiments on leading LLMs demonstrate tha
t SpatialJB achieves a nearly 100\% ASR and consistently maintains a success rat
e exceeding 75\% even against advanced output guardrails like the OpenAI Moderat
ion API, outperforming current jailbreak techniques by a significant margin.

While **SpatialJB** advances LLM safety research by exposing guardrail weaknesse
s and highlighting spatial semantics, we also propose and evaluate baseline defe
nse strategies to prevent its potential misuse.

From Growing to Looping: A Unified View of Iterative Computation in LLMs
Ferdinand Kapl, Emmanouil Angelis, Kaitlin Maile, Johannes von Oswald, Stefan Ba
uer
Looping, reusing a block of layers across depth, and depth growing, training sha
llow-to-deep models by duplicating middle layers, have both been linked to stron
ger reasoning, but their relationship remains unclear. We provide a mechanistic
unification: looped and depth-grown models exhibit convergent depth-wise signatu
res, including increased reliance on late layers and recurring patterns aligned
with the looped or grown block. These shared signatures support the view that th
eir gains stem from a common form of iterative computation. Building on this con
nection, we show that the two techniques are adaptable and composable: applying
inference-time looping to the middle blocks of a depth-grown model improves accu
racy on some reasoning primitives by up to $2\times$, despite the model never be
ing trained to loop. Both approaches also adapt better than the baseline when gi
ven more in-context examples or additional supervised fine-tuning data. Addition
ally, depth-grown models achieve the largest reasoning gains when using higher-q
uality, math-heavy cooldown mixtures, which can be further boosted by adapting a
 middle block to loop. Overall, our results position depth growth and looping as
 complementary, practical methods for inducing and scaling iterative computation
 to improve reasoning.

Skipping the Zeros in Diffusion Models for Sparse Data Generation
Phil Ostheimer, Mayank Nagda, Andriy Balinskyy, Gabriel Vicente Rodrigues, Jean
Radig, Carl Herrmann, Stephan Mandt, Marius Kloft, Sophie Fellenz
Diffusion models (DMs) excel on dense continuous data, but are not designed for
sparse continuous data. They do not model exact zeros that represent the deliber
ate absence of a signal. As a result, they erase sparsity patterns and perform u
nnecessary computation on mostly zero entries. With Sparsity-Exploiting Diffusio
n (SED), we model only non-zero values, preserving sparsity. SED delivers comput
ational savings while maintaining or improving generation quality by skipping ze
ros during training and inference. Across physics and biology benchmarks, SED ma
tches or surpasses conventional DMs and domain-specific baselines, while vision
experiments provide intuitive insights into the limitations of dense DMs and the
 benefits of SED.

Bridging RGB and RAW: Single-step Deterministic Flow with Homogeneous Representa
tion Alignment
Diedong Feng, Peiyi Zeng, Zhen Liu, Zhongyang Li, Bing Zeng, Shuaicheng Liu
Reconstructing high-fidelity RAW sensor data from processed RGB images is a fund
amental yet ill-posed problem, plagued by irreversible information loss and comp
lex non-linear ISP transformations. While generative models offer high-quality r
econstruction, they suffer from prohibitive computational costs. Conversely, dom
inant regression-based methods are fast but susceptible to incoherent observatio
nal deviations, often yielding over-smoothed predictions that drift from the aut
hentic signal manifold. To reconcile this trade-off, we propose SHADE, a Single-
step Homogeneous Aligned DEterministic flow framework. We validate that, unlike
point-to-point regression, the single-step deterministic flow captures global tr
ansport trends and enables intrinsic robustness against input perturbations. Fur
thermore, we introduce Homogeneous Representation Alignment to maximize fidelity
. By leveraging a homogeneously initialized student-teacher DINO pair, this mech
anism enforces alignment within a shared feature space, significantly amplifying
 the representational capacity. Extensive experiments demonstrate that SHADE ach
ieves state-of-the-art performance on multiple benchmarks, establishing a new pa
radigm for accurate and efficient sensor data reconstruction.
****
HE-SNR: Uncovering Latent Logic via Entropy for Guiding Mid-Training on SWE-benc
h
Yueyang Wang, Jiawei Fu, Baolong Bi, Xili Wang, Xiaoqing Liu
SWE-bench has emerged as the premier benchmark for evaluating Large Language

Models on complex software engineering tasks. While these capabilities are fundamentally acquired during the *mid-training* phase and subsequently elicited during Supervised Fine-Tuning (SFT), there remains a critical deficit in metrics capable of guiding mid-training effectively. Standard metrics such as Perplexity (PPL) are compromised by the "Long-Context Tax" and exhibit weak correlation with downstream SWE performance. In this paper, we bridge this gap by first introducing a rigorous data filtering strategy. Crucially, we propose the **Entropy Compression Hypothesis**, redefining intelligence not by scalar Top-1 compression, but by the capacity to structure uncertainty into Entropy-Compressed States of low orders ("reasonable hesitation"). Grounded in this fine-grained entropy analysis, we formulate a novel metric, **HE-SNR** (High-Entropy Signal-to-Noise Ratio). We validate our approach on models with up to 560B parameters across different context windows (32K/128K). This work provides both the theoretical foundation and practical tools for optimizing the latent potential of LLMs in complex engineering domains.

Dropout Universality: Scaling Laws and Optimal Scheduling at the Edge-of-Chaos

Lucas Fernandez-Sarmiento

We develop a mean-field theory of dropout as a perturbation of critical signal propagation at the edge of chaos, and show that it predicts a simple, no-cost change to standard practice: front-loaded dropout schedules cut test loss by 18–35% over constant dropout in MLPs and Vision Transformers at fixed budget. The theoretical mechanism is that dropout shifts the perfect-alignment fixed point, making the depth scale for information propagation finite even at critical initialization. We derive critical and crossover scaling laws for correlation decay and establish that smooth activations and kinked, ReLU-like activations constitute distinct universality classes, with different critical exponents and a universal two-parameter scaling collapse in detuning and dropout strength. The distinction traces to the analytic structure of the correlation map: smooth activations admit a Taylor expansion near perfect alignment, while kinked activations develop a branch point with universal non-analyticity. As a corollary, the framework yields saturated dropout profiles under fixed budget; a regularization-reach argument then selects front-loaded schedules, with accuracy gains as a consistent secondary effect. We also discuss how the same Gaussian-kernel structure extends the theory beyond MLPs toward CNNs and residual architectures.

PaperBanana: Automating Academic Illustration for AI Scientists

Dawei Zhu, Rui Meng, Yale Song, Xiyu Wei, Sujian Li, Tomas Pfister, Jinsung Yoon

Despite rapid advances in autonomous AI scientists powered by language models, generating publication-ready illustrations remains a labor-intensive bottleneck in the research workflow.

To lift this burden, we introduce PaperBanana, an agentic framework for automated generation of publication-ready academic illustrations.

Powered by state-of-the-art VLMs and image generation models,

PaperBanana orchestrates specialized agents to retrieve references, plan content and style, render images, and iteratively refine via self-critique.

To rigorously evaluate our framework, we introduce PaperBananaBench, comprising 292 test cases for methodology diagrams curated from NeurIPS 2025 publications, covering diverse research domains and illustration styles.

Comprehensive experiments demonstrate that PaperBanana consistently outperforms leading baselines in faithfulness, conciseness, readability, and aesthetics.

We further show that our method effectively extends to the generation of high-quality statistical plots.

Collectively,

PaperBanana paves the way for the automated generation of publication-ready illustrations.

SD-MoE: Spectral Decomposition for Effective Expert Specialization

Ruijun Huang, Fang Dong, Xin Zhang, Anrui Chen, Hengjie Cao, Zhendong Huang, Jixian Zhou, Mengyi Chen, Yifeng Yang, Mingzhi Dong, Yujiang Wang, Jinlong Hou, Qin

Lv, Robert P. Dick, Yuan Cheng, Fan Yang, Tun Lu, Chun Zhang, Li Shang
Mixture-of-Experts (MoE) architectures scale Large Language Models via expert specialization induced by conditional computation. In practice, however, expert specialization often fails: some experts become functionally similar, while others functioning as de facto shared experts, limiting the effective capacity and model performance.
In this work, we analysis from a spectral perspective on parameter and gradient spaces, uncover that
(1) experts share highly overlapping dominant spectral components in their parameters,
(2) dominant gradient subspaces are strongly aligned across experts, driven by ubiquitous low-rank structure in human corpus, and
(3) gating mechanisms preferentially route inputs along these dominant directions, further limiting specialization.
To address this, we propose Spectral-Decoupled MoE (SD-MoE), which decomposes both parameter and gradient in the spectral space.
SD-MoE improves performance across downstream tasks, enables effective expert specialization, incurring minimal additional computation, and can be seamlessly integrated into a wide range of existing MoE architectures, including Qwen and DeepSeek.
****
HyperMLP: An Integrated Perspective for Sequence Modeling
Jiecheng Lu, Shihao Yang
Self-attention is often viewed as probabilistic query-key lookup, motivating designs that preserve normalized attention scores and fixed positional semantics. We advocate a simpler and more unified perspective: an autoregressive attention head can be viewed as a dynamic two-layer MLP whose weights are instantiated from the context history. From this view, attention scores form an ever-growing hidden representation, and standard MLP activations such as ReLU or GLU naturally implement input-conditioned selection over a context-dependent memory pool rather than a probability distribution. Based on this formulation, we introduce \textbf{HyperMLP} and \textbf{HyperGLU}, which learn dynamic mixing in both feature space and sequence space, using a reverse-offset (lag) layout to align temporal mixing with autoregressive semantics. We provide theoretical characterizations of the expressivity and implications of this structure, and empirically show that HyperMLP/HyperGLU consistently outperform strong softmax-attention baselines under matched parameter budgets.
****
SkillTrojan: Backdoor Attacks on Skill-Based Agent Systems
Yunhao Feng, Yifan Ding, Yingshui Tan, Boren Zheng, Xiaolong Li, Kun Zhai, Li Yishan, Yanming Guo, Wenke Huang
Skill-based agent systems tackle complex tasks by composing reusable skills, improving modularity and scalability while introducing a largely unexamined security attack surface. We propose \textbf{SkillTrojan}, a backdoor attack that targets skill implementations rather than model parameters or training data. SkillTrojan embeds malicious logic inside otherwise plausible skills and leverages standard skill composition to reconstruct and execute an attacker-specified payload. The attack partitions an encrypted payload across multiple benign-looking skill invocations and activates only under a predefined trigger. SkillTrojan also supports automated synthesis of backdoored skills from arbitrary skill templates, enabling scalable propagation across skill-based agent ecosystems. To enable systematic evaluation, we release a dataset of 3,000+ curated backdoored skills spanning diverse skill patterns and trigger–payload configurations. We instantiate SkillTrojan in a representative code-based agent setting and evaluate both clean-task utility and attack success rate. Our results show that skill-level backdoors can be highly effective with minimal degradation of benign behavior, exposing a critical blind spot in current skill-based agent architectures and motivating defenses that explicitly reason about skill composition and execution. Concretely, on EHR SQL, SkillTrojan attains up to \textbf{97.2\%} ASR while maintaining \textbf{89.3\%} clean ACC on GPT-5.2-1211-Global. Code is available at \url{https:

//github.com/Yunhao-Feng/SkillTrojan}.
****
Artificial Hippocampus Networks for Efficient Long-Context Modeling
Yunhao Fang, Weihao Yu, Shu Zhong, Qinghao Ye, Xuehan Xiong, Lai Wei
Long-sequence modeling faces a fundamental trade-off between the efficiency of compressive fixed-size memory in RNN-like models and the fidelity of lossless growing memory in attention-based Transformers. Inspired by the Multi-Store Model in cognitive science, we introduce a memory framework of artificial neural networks. Our method maintains a sliding window of the Transformer's KV cache as lossless short-term memory, while a learnable module termed Artificial Hippocampus Network (AHN) recurrently compresses out-of-window information into a fixed-size compact long-term memory. To validate this framework, we instantiate AHNs using modern RNN-like architectures, including Mamba2, DeltaNet, and GatedDeltaNet to augment open-weight base LLMs. We also propose an efficient self-distillation method where the base model' all parameters are frozen and only the parameters from AHNs are optimized. For inference, our method sets a default large sliding window size of 32k for attention, and AHNs activate only when the sequence length exceeds the 32k window, addressing the quadratic-complexity issue of attention that emerges at that scale. Extensive experiments on long-context benchmarks LV-Eval and InfiniteBench demonstrate that AHN-augmented models consistently outperform sliding window baselines and achieve performance comparable or even superior to full-attention models, while substantially reducing computational and memory requirements. For instance, augmenting the Qwen2.5-3B-Instruct with AHNs reduces inference FLOPs by 40.5% and memory cache by 74.0%, while improving its average score on LV-Eval (128k sequence length) from 4.41 to 5.88.

Alleviating Observation Bias via Causal-Invariant Meta-Learning for Unbalanced Incomplete Multi-view Clustering
Jiaqi Jin, Siwei Wang, Taichun Zhou, Zhibin Dong, Siqi Wang, Miaomiao Li, Xinwang Liu, En Zhu
In real-world scenarios, multi-view data often exhibits significant imbalance in missing patterns across views, where observation rates vary substantially among different views. Such observation bias makes it difficult for cross-view associations learned from limited complete samples to generalize to incomplete samples, leading to challenging cross-view recovery. Meanwhile, observation bias acts as a confounder, causing clustering predictions to spuriously depend on low-missing-rate views. To address these challenges, we propose CIMLN, a novel **C**ausal-**I**nvariant **M**eta-**L**earning **N**etwork that alleviates observation bias for unbalanced incomplete multi-view clustering. The context-aware meta-generation module formulates view recovery as a meta-learning task, enabling rapid adaptation to incomplete samples by encoding global statistical relationships through context information. The causal-invariant structure learning module constructs counterfactual scenarios by artificially masking low-missing-rate views, enforcing clustering consistency across different observation patterns. Extensive experiments on eight benchmarks demonstrate the effectiveness of CIMLN. The code is available at https://github.com/jinjiaqi1998/CIMLN.
****
LUVE : Latent-Cascaded Ultra-High-Resolution Video Generation with Dual Frequency Experts
Chen Zhao, Jiawei Chen, Hongyu Li, Zhuoliang Kang, Shilin Lu, Xiaoming Wei, Kai Zhang, Jian Yang, Ying Tai
Recent advances in video diffusion models have significantly improved visual quality, yet ultra-high-resolution (UHR) video generation remains a formidable challenge due to the compounded difficulties of motion modeling, semantic planning, and detail synthesis. To address these limitations, we propose \textbf{LUVE}, a \textbf{L}atent-cascaded \textbf{U}HR \textbf{V}ideo generation framework built upon dual frequency \textbf{E}xperts. LUVE employs a three-stage architecture comprising low-resolution motion generation for motion-consistent latent synthesis, video latent upsampling that performs resolution upsampling directly in the latent space to mitigate memory and computational overhead, and high-resolution co

ntent refinement that integrates low-frequency and high-frequency experts to joi ntly enhance semantic coherence and fine-grained detail generation. Extensive ex periments demonstrate that our LUVE achieves superior photorealism and content f idelity in UHR video generation, and comprehensive ablation studies further vali date the effectiveness of each component.

Semantic Router: On the Feasibility of Hijacking MLLMs via a Single Adversarial Perturbation
Changyue Li, Jiaying Li, Youliang Yuan, Jiaming He, Zhicong Huang, Pinjia He
Multimodal Large Language Models (MLLMs) are increasingly deployed in stateless systems, such as autonomous driving and robotics.
This paper investigates a novel threat: Semantic-Aware Hijacking. We explore the feasibility of hijacking multiple stateless decisions simultaneously using a si ngle universal perturbation.
We introduce the Semantic-Aware Universal Perturbation (SAUP), which acts as a s emantic router, "actively" perceiving input semantics and routing them to distin ct, attacker-defined targets.
To achieve this, we conduct a theoretical and empirical analysis on the geometri c properties in the latent space. Guided by these insights, we propose the Seman tic-Oriented (SORT) optimization strategy and annotate a new dataset with fine-g rained semantics to evaluate performance.
Extensive experiments on three representative MLLMs demonstrate the fundamental feasibility of this attack, achieving a 66% attack success rate over five target s using a single frame against Qwen.
****
RubricRobustness: Evaluating the Sensitivity of Rubrics-Based Benchmarks to Simp le Perturbations
Manasi Sharma
The advancement of Large Language Models (LLMs) into higher-level reasoning doma ins has rendered traditional heuristic evaluators insufficient for long-form ope n-ended responses, precipitating the widespread adoption of rubric-based benchma rks. While these frameworks utilize expert-curated criteria and LLM-as-a-judge t o assess open-ended generation, the intrinsic robustness of these evaluation har nesses to fundamental validity assessments remains critically under-investigated . To bridge this gap, we introduce RubricRobustness, a systematic sensitivity an alysis framework that subjects these benchmarks to three common sense perturbati ons: *semantic negation*, *stochastic deletion* and *irrelevant addition*. We in vestigate the extent to which manipulating the semantic veracity of a model's re sponse impacts its resulting score by applying the robustness framework to two o f the most popular rubrics-based benchmarks: HealthBench and WildBench. Our find ings reveal systematic vulnerabilities: while both benchmarks respond sharply to semantic negation (e.g., degradation slopes of approximately -0.38 on HealthB ench and -0.55 on WildBench), they are substantially less responsive to irrele vant addition, often requiring over 35% of sentences to be perturbed before indu cing even a 25% score drop. We argue that perturbation-based sensitivity analyse s of this form are a necessary prerequisite for validating rubric coverage, ensu ring that automated evaluation frameworks reliably penalize basic semantic failu res. We will release our framework as an open-source tool for building more resi lient benchmarks.
****
Romberg-Extrapolated Zeroth-Order Gradient Estimator: Higher-Order Bias Reductio n with Preserved Leading Directional Variance
Hongcheng Dong, Wenqiang Pu, Licheng Zhao, Rui Zhou, Feng Yin
Zeroth-order optimization is widely used when gradients are unavailable, but the standard two-point estimator suffers from $\mathcal{O}(r^2)$ truncation bias at smoothing radius r.
Existing bias-reduction schemes typically increase the leading directional varia nce under a fixed number of function evaluations per gradient estimate, while va riance-reduction schemes generally do not improve the bias order.
We propose Romberg-ZOGE, which forms a Romberg-extrapolated linear combination o

f two-point differences evaluated at radii $\{r/2^k\}_{k=0}^R$ while reusing the same perturbation direction across all radii.
With appropriately chosen weights, Romberg-ZOGE cancels the first R even-order truncation terms and achieves $\mathcal{O}(r^{2R+2})$ bias under $(2R{+}2)$-order smoothness, while preserving the leading directional variance constant of the two-point estimator up to higher-order residual terms.
We further characterize the stochastic-oracle setting by deriving an explicit noise-amplification factor and corresponding bias and variance bounds.
Experiments on synthetic benchmarks, simulator-based wireless optimization, and black-box prompt tuning of OPT-1.3B demonstrate faster and more stable zeroth-order SGD when the number of function evaluations per gradient estimate is fixed.
****
Mitigating Gradient Pathology in PINNs through Aligned Constraint
Yichen Luo, Peiyu Zhu, Dongxiao Hu, Jia Wang, Tailin Wu, Dapeng Lan, Yu Liu, Zhibo Pang
While Physics-Informed Neural Networks (PINNs) are powerful for solving Partial Differential Equations (PDEs), their training is often paralyzed by gradient pathology. The gradients from the PDE residuals and boundary constraints oppose each other, trapping the model in local minima. Current solutions, such as adaptive weighting or hard constraints, either fail to fundamentally resolve this ill-conditioning or are limited to simple geometries. In this study, we systematically analyze the possible causes of this gradient pathology from the perspectives of loss landscapes and optimization dynamics. Based on the obtained conclusion, we propose Constraint-Aligned loss with Manifold Lifting (CAML). By reformulating all zeroth-order terms into aligned constraints, our method effectively mitigates gradient conflicts. In addition, we introduce a delay factor to help the optimizer skip the high-curvature area. Experiments demonstrate that our CAML significantly enhances numerical stability and efficiency in highly complex PINN problems. Our code is open-sourced on [CAML](https://github.com/YichenLuo-0/CAML).

Outcome-Aware Spectral Feature Learning for Instrumental Variable Regression
Dimitri Meunier, Jakub Wornbard, Vladimir R Kostic, Antoine Moulin, Alek Fröhlich, Karim Lounici, Massimiliano Pontil, Arthur Gretton
We address the problem of causal effect estimation in the presence of hidden confounders using nonparametric instrumental variable (IV) regression. An established approach is to use estimators based on learned \emph{spectral features}, that is, features spanning the top singular subspaces of the operator linking treatments to instruments. While powerful, such features are agnostic to the outcome variable. Consequently, the method can fail when the true causal function is poorly represented by these dominant singular functions.

To mitigate, we introduce Augmented Spectral Feature Learning, a framework that makes the feature learning process outcome-aware. Our method learns features by minimizing a novel contrastive loss derived from an augmented operator that incorporates information from the outcome. By learning these task-specific features, our approach remains effective even under spectral misalignment. We provide a theoretical analysis of this framework and validate our approach on challenging benchmarks.
****
GenShield: Unified Detection and Artifact Correction for AI-Generated Images
Zhipei Xu, Xuanyu Zhang, Youmin Xu, Qing Huang, Shen Chen, Taiping Yao, Shouhong Ding, Jian Zhang
Diffusion-based image synthesis has made AI-generated images (AIGI) increasingly photorealistic, raising urgent concerns about authenticity in applications such as misinformation detection, digital forensics, and content moderation. Despite the substantial advances in AIGI detection, how to correct detected AI-generated images with visible artifacts and restore realistic appearance remains largely underexplored. Moreover, few existing work has established the connection between AIGI detection and artifact correction. To fill this gap, we propose GenShield, a unified autoregressive framework that jointly performs explainable AIGI det

ection and controllable artifact correction in a closed loop from diagnosis to r
estoration, revealing a mutually reinforcing relationship between these two task
s. We further introduce a Visual Chain-of-Thought based curriculum learning str
ategy that enables self-explained, multi-step "diagnose-then-repair" correction
with an explicit stopping criterion. A high-quality dataset with large-scale "ar
tifact-restored" pairs is also constructed alongside a unified evaluation pipeli
ne. Extensive experiments on our correction benchmark and mainstream AIGI detect
ion benchmarks demonstrate state-of-the-art performance and strong generalizatio
n of our method.

Leveraging Machine Unlearning for Cost-Efficient Preference Alignment
XiaoHua Feng, Yuyuan Li, HuWei Ji, Li Zhang, Jiaming Zhang, Tianyu Du, Chaochao Chen
Despite advances in Preference Alignment (PA) for Large Language Models (LLMs),
mainstream methods like reinforcement learning with human feedback face notable
challenges. These approaches require high-quality datasets of positive preferenc
e examples, which are costly to obtain and computationally intensive. The LLM un
learning technique presents a promising alternative by directly removing the inf
luence of negative examples. However, current research has primarily focused on
empirical validation, lacking systematic quantitative analysis. To bridge this g
ap, we propose a framework linking PA with LLM unlearning. Through bi-level opti
mization, we first quantify how unlearning specific negative examples impacts PA
performance. Our analysis reveals that these effects vary substantially across
negative examples. Building on this insight, we pose a crucial question: how can
we optimally select and weight negative examples for unlearning to maximize PA
performance? To answer this, we propose Unlearning to Align (U2A), which leverag
es bi-level optimization to efficiently select and unlearn examples for optimal
PA performance. We validate the proposed method through extensive experiments, w
ith results confirming its effectiveness. Our code is available at https://anony
mous.4open.science/r/U2A-9E75.

Optimal Design for Multinomial Logit Model with Applications to Best Assortment Identification
Joongkyu Lee, Min-hwan Oh
We study optimal experimental design for multinomial logit (MNL) bandits, where
an agent repeatedly selects a subset of K items from a ground set of size N
and observes single-choice feedback. Unlike linear or generalized linear bandits
, MNL bandits have a combinatorial action space, which makes classical optimal d
esign approaches and naive optimization over all subsets computationally intract
able. We propose a computationally efficient optimal design framework for MNL mo
dels that achieves both statistical efficiency and scalability through two compl
ementary approaches: (i) an exact or certified-approximate reformulation of the
design oracle as a 0-1 mixed-integer linear program (MILP) with solver-certi
fied early stopping, and (ii) a fully polynomial-time lifted design that replace
s the nonlinear objective with a tractable surrogate. Using the Kiefer-Wolfowitz
equivalence theorem, we establish near G-optimality guarantees and characterize
the induced statistical-computational trade-offs. As an application, we develop
a best assortment identification algorithm for MNL bandits with linear utilitie
s and non-uniform revenues, and prove an instance-dependent sample complexity of
$\tilde{\mathcal{O}}\big(\frac{d \log N}{\Delta^2}\big)$, where d is the feat
ure dimension, N is the number of arms, and Δ is the minimum revenue ga
p.

LightningRL: Breaking the Accuracy–Parallelism Trade-off of Block-wise dLLMs via Reinforcement Learning
Yanzhe Hu, Yijie Jin, Pengfei Liu, Kai Yu, Zhijie Deng
Diffusion Large Language Models (dLLMs) enable parallel token generation, and th
eir block-wise variants have attracted significant attention. However, existing
dLLMs usually exhibit an accuracy–parallelism trade-off, where raising tokens pe
r forward (TPF) via aggressive parallel decoding often degrades task accuracy. T

o address this, we suggest developing a post-training approach to directly optim
ize the speed–quality frontier of pre-trained dLLMs. Conceptually, we do not req
uire the model to decode aggressively along all sampling trajectories, but rathe
r to find several highly parallelizable ones that can yield correct results. To
this end, we resort to a reinforcement learning paradigm, i.e., LightningRL, to
optimize rewards regarding both the final accuracy and inference parallelism. Li
ghtningRL follows the Group Relative Policy Optimization (GRPO) framework, with
further improvements for dLLMs: 1) stabilized training via per-reward decoupled
normalization, 2) token-level negative log-likelihood (NLL) loss on correct traj
ectories for regularization, and 3) improved training efficiency through dynamic
 sampling with TPF-aware filtering. Across maths and code tasks, LightningRL con
sistently advances the Pareto frontier, maintaining competitive accuracy while i
ncreasing parallelism to an average TPF of 7.3 (up to 11.10 on MBPP).

Forget-It-All: Multi-Concept Machine Unlearning via Concept-Aware Neuron Masking
Kaiyuan Deng, Bo Hui, Gen Li, Jie Ji, Minghai Qin, Geng Yuan, Xiaolong Ma
The widespread adoption of text-to-image (T2I) diffusion models has raised conce
rns about their potential to generate copyrighted, inappropriate, or sensitive i
magery. As a practical solution, *machine unlearning* aims to erase unwanted con
cepts without retraining from scratch. While most existing methods are effective
 for single-concept unlearning, they often struggle when removing multiple conce
pts, causing significant challenges in unlearning effectiveness, generation qual
ity, and sensitivity to hyperparameters and datasets. We take a unique perspecti
ve on multi-concept unlearning by leveraging model sparsity and propose the **F*
*orget **I**t **A**ll (FIA) framework. FIA first introduces *Contrastive Concept
 Saliency* to quantify each weight connection's contribution to a target concept
. It then identifies *Concept Sensitive Neurons* by combining temporal and spati
al information, ensuring that only neurons consistently responsive to the target
 concept are selected. Finally, FIA constructs masks from the identified neurons
 and fuses them into a unified multi-concept mask, where *Concept Agnostic Neuro
ns* that broadly support general content generation are preserved while concept-
specific neurons are pruned to remove the targets. FIA is training-free and requ
ires minimal hyperparameter tuning for new tasks, enabling plug-and-play use. Ex
tensive experiments across three distinct unlearning tasks demonstrate that FIA
achieves more reliable multi-concept unlearning, improving forgetting effectiven
ess while maintaining generation fidelity and quality. Code is available at [htt
ps://github.com/kaiyuan02415/Forget-It-All](https://github.com/kaiyuan02415/Forg
et-It-All)

Characterizing Vision-Language-Action Models across XPUs: Constraints and Accele
ration for On-Robot Deployment
Kaijun Zhou, Qiwei Chen, Da Peng, Zhiyang Li, Xijun Li, Jinyu Gu
Vision-Language-Action (VLA) models are promising for generalist robot control,
but on-robot deployment is bottlenecked by real-time inference under tight cost
and energy budgets.
Most prior evaluations rely on desktop-grade GPUs, obscuring the trade-offs and
opportunities offered by heterogeneous edge accelerators (GPUs/XPUs/NPUs).
We present a systematic framework for low-cost VLA deployment via model--hardwar
e co-characterization.
First, we build a cross-accelerator leaderboard and evaluate model--hardware pai
rs under \textbf{CET} (Cost, Energy, Time), showing that ``right-sized'' edge de
vices can be more cost-/energy-efficient than flagship GPUs while meeting contro
l-rate constraints.
Second, using fine-grained SM tracing and Roofline analysis, we uncover a consis
tent two-phase inference pattern: a compute-bound VLM backbone followed by a mem
ory-bound Action Expert, which induces phase-dependent underutilization and hard
ware inefficiency.
Finally, guided by these insights, we propose \textbf{DP-Cache} and \textbf{V-AE
Fusion} to reduce diffusion redundancy and enable asynchronous pipeline parallel
ism, achieving up to \(2.9\times\) speedup on GPUs and \(6\times\) on edge NPUs

with only marginal success degradation.
The example leaderboard website is: \url{https://vla-leaderboard-01.vercel.app/}

Online Compatible Reward Identification from Preference Feedback
Simone Drago, Marco Mussi, Alberto Maria Metelli
In reinforcement learning, human preference feedback is emerging as a viable alt ernative to expert-designed reward functions, which can be difficult to engineer in real-world problems. However, despite the growing importance of preference f eedback, how to effectively *elicit* preferences remains a fundamental open prob lem. This work focuses on the *compatible reward identification* task. The aim i s to derive, starting from preference feedback, a reward function compatible wit h the observed preferences and accurate across the *entire* state-action space, ensuring higher transferability, safety, and interpretability. Indeed, the most common *reinforcement learning from human feedback* objective is to learn the *o ptimal policy*, requiring accuracy only in the portion of the state-action space that the agent visits. However, this goal cannot provide the same guarantees as compatible reward identification. First, we discuss commonalities and differenc es between the two goals. Then, we consider deterministic preferences, deriving the minimum number of interactions needed to identify the set of compatible rewa rds, and showing that using fewer queries may lead to arbitrarily large suboptim ality. Finally, we focus on stochastic preferences generated via the Bradley-Ter ry (BT) model. We introduce the concepts of *query basis* and its *index*, relat ing them to the problem complexity. Upon this, we discuss the connection between the index of a basis and the BT model, as well as the limitations that the mode l induces in this setting. Additionally, we devise an algorithm to identify a ne arly-optimal query basis with polynomial human query complexity.

TMD-Bench: A Multi-Level Evaluation Paradigm for Music–Dance Co-Generation
Xiaoda Yang, Majun Zhang, Changhao Pan, Nick Huang, Yang Yuguang, Fan Zhuo, Peng fei Zhou, Jin Zhou, Sizhe Shan, Shan Yang, Miles Yang, Yang You, Zhou Zhao
Unified audio--visual generation is rapidly gaining industrial and creative rele vance, enabling applications in virtual production and interactive media. Howeve r, when moving from general audio--video synthesis to music–dance co-generation, the task becomes substantially harder: musical rhythm, phrasing, and accents mu st drive choreographic motion at fine temporal resolution, and such rhythmic cou pling is not captured by unimodal metrics or generic audiovisual consistency sco res used in current evaluation practice.
We introduce TMD-Bench, a benchmark for text-driven music–dance co-generation th at assesses systems across unimodal generation quality, instruction adherence, a nd cross-modal rhythmic alignment. The benchmark integrates computable physical metrics with perceptual multimodal judgments, and is supported by a curated rhyt hm-aligned music–dance dataset and a fine-grained Music Captioner for structured music semantics.
TMD-Bench further reveals that (i) modern commercial audio--visual models (e.g., Veo 3, Sora 2) produce high-quality music and video, while rhythmic coupling re mains less consistently optimized and leaves room for improvement, and (ii) our unified baseline RhyJAM trained on rhythm-aligned data achieves competitive beat -level synchronization while maintaining competitive unimodal fidelity. This pre sents prospects for building next-generation music–dance models that explicitly optimize rhythmic and kinetic coherence. The code is available at https://github .com/MM-Speech/TMD-Bench.

Beyond Detection: A Structure-Aware Framework for Scene Text Tracking
Chenmin Yu, Liu Yu, Daiqing Wu, Gengluo Li, Zeyu Chen, Yu ZHOU
Modern visual object trackers show impressive results on general targets, yet th eir performance drops substantially when dealing with scene text. Although curre ntly underexplored, tracking text in videos is essential for dynamic text manipu lations such as segmentation, removal, and editing. To fill this gap, this paper formalizes this specific task as Scene Text Tracking and presents the first sys

tematic work for it. We identify three primary challenges in this task: 1) severe geometric distortions from perspective shifts, 2) high visual ambiguity across different instances, and 3) high sensitivity to fine-grained structural details. To address these issues, we propose SymTrack, a unified detection-free framework with synergistic dual-branch design. It integrates a Cross-Expert Calibration mechanism to reduce semantic bias, along with a Predictive Token Rectification mechanism to correct structural imbalances, complemented by an Adaptive Inference Engine that stabilizes predictions under motion constraints. Considering the lack of dedicated benchmarks for this task, we utilize three datasets from video text spotting to construct a benchmark with high-quality annotations. Extensive experiments demonstrate that SymTrack sets the new state-of-the-art on all three benchmarks, outperforming previous best trackers by up to 11.97\% AUC on $ \text{BOVText}_{\text{SOT}} $. Overall, our work promotes efficient and thorough text tracking, paving the way toward more generalized video text manipulation.

Belief Propagation Converges to Gaussian Distributions in Sparsely-Connected Factor Graphs
Tom Yates, Yuzhou Cheng, Ignacio Alzugaray, Danyal Akarca, Pedro A. M. Mediano, Andrew J. Davison
Belief Propagation (BP) is a powerful algorithm for distributed inference in probabilistic graphical models, however it quickly becomes infeasible for practical compute and memory budgets. Many efficient, non-parametric forms of BP have been developed, but the most popular is Gaussian Belief Propagation (GBP), a variant that assumes all distributions are locally Gaussian. GBP is widely used due to its efficiency and empirically strong performance in applications like computer vision or sensor networks – even when modelling non-Gaussian problems. In this paper, we seek to provide a theoretical guarantee for when Gaussian approximations are valid in highly non-Gaussian,
sparsely-connected factor graphs performing BP (common in Spatial AI). We leverage the Central Limit Theorem to prove mathematically that variables’ beliefs under BP converge to a Gaussian distribution in complex, loopy factor graphs obeying our 4
key assumptions. We then confirm experimentally that variable beliefs become increasingly Gaussian after just a few BP iterations
in a stereo depth estimation task.

A geometric relation of the error introduced by sampling a language model's output distribution to its internal state
Albert F. Modenbach
GPT-style language models are sensitive to single-token changes at generation points where the predicted probability distribution is spread across multiple tokens. Viewing this sensitivity as a geometric property, we derive an $\mathfrak{so}(n)$-valued 1-form that depends only on the geometry of the token embeddings. Despite this purely geometric origin, we show that its curvature is semantically meaningful: on chess reasoning tasks, the curvature couples to the world model of an off-the-shelf instruction-tuned model, with transformations clustering by board region and respecting piece importance. Our findings suggest that token space geometry directly reflects how models internally represent problems.

VideoLoom: A Video Large Language Model for Joint Spatial-Temporal Understanding
Jiapeng Shi, Junke Wang, Zuyao You, Bo He, Zuxuan Wu
Recent advancements in Video Large Language Models (Video LLMs) have demonstrated impressive results, yet existing approaches handle either temporal or spatial dimension in isolation, struggling in the analysis of complex events that require spatial-temporal integration. To bridge this gap, we propose VideoLoom, a unified Video LLM for joint spatial-temporal understanding. To facilitate the development of fine-grained spatial and temporal localization capabilities, we curate LoomData-8.7k, a character-centric video dataset with temporally grounded and spatially localized captions. With this, VideoLoom achieves the state-of-the-art performance across a variety of spatial and temporal benchmarks. In addition, we

introduce LoomBench, a benchmark consisting of temporal, spatial, and compositio
nal video–question pairs, with a novel metric J&$F_{bi-fore}$, enabling a comp
rehensive evaluation of Video LLMs from diverse aspects. Collectively, these con
tributions offer a universal and effective suite for joint spatial-temporal vide
o understanding, setting a new standard in multimodal intelligence.

Efficient Distributionally Robust Assortment Optimization in MNL Bandits
Yunfan Zhang, Yuxuan Han, Zhengyuan Zhou
We investigate the distributionally robust assortment optimization (DRAO) proble
m under the contextual multinomial logit (MNL) choice model, where the decision-
maker seeks to maximize revenue against worst-case distributional deviations. To
 address potential distribution shifts relative to the observed data environment
, we study DRAO under ambiguity sets defined by three divergences: total variati
on (TV), Kullback–Leibler (KL), and chi-square (χ^2). Incorporating robust
concerns poses challenges for both algorithm design and theoretical analysis. By
 leveraging strong duality results from the distributionally robust optimization
 literature and integrating them into the assortment optimization procedures, we
 develop tailored polynomial-time algorithms under each divergence. We further p
rovide a theoretical analysis and establish sample complexity bounds for all thr
ee robust formulations.

KITE: Knowledge-Guided Probabilistic Modeling for Time Series Forecasting with E
xogenous Variables
Hanyin Cheng, Jingrong Zhou, Yang Shu, Chenjuan Guo
Probabilistic forecasting with exogenous variables is vital for decision-making
but remains underexplored compared to deterministic methods. We propose KITE, a
knowledge-guided probabilistic modeling framework designed to bridge this gap by
 addressing two key bottlenecks: (1) topological disparity in sampling initializ
ation and (2) spurious covariate correlations during the iterative conditional g
eneration process. KITE introduces a *History-Conditional Manifold* to construct
 an informative source distribution from historical dynamics, effectively anchor
ing the starting point closer to the target space. Additionally, a *Knowledge-Gu
ided Conditioning* module is developed to regularize variable interactions using
 statistical priors, suppressing spurious correlations and enhancing the robustn
ess of covariate conditioning. Extensive experiments demonstrate that KITE outpe
rforms state-of-the-art methods in both deterministic and probabilistic forecast
ing.

World-Shaper: A Unified Framework for 360° Panoramic Editing
Dong Liang, Yuhao LIU, Jinyuan Jia, Youjun Zhao, Rynson W. H. Lau
Being able to edit panoramic images is crucial for creating realistic 360° visua
l experiences. However, existing perspective-based image editing methods fail to
 model the spatial structure of panoramas. Conventional cube-map decompositions
attempt to overcome this problem but inevitably break global consistency due to
their mismatch with spherical geometry. Motivated by this insight, we reformulat
e panoramic editing directly in the equirectangular projection (ERP) domain and
present World Shaper, a unified geometry-aware framework that supports five dist
inct editing operations within a single ERP-native representation. To address th
e latitude-dependent geometric distortion inherent in ERP, we introduce a geomet
ry-aware learning strategy comprising distortion-aware attention modulation (DAA
M), which steers cross-attention with latitude-dependent strength at the feature
 level; layered shape loss (LSL), which enforces per-object geometric supervisio
n at the output level; and progressive curriculum training to internalize panora
mic priors. To overcome the scarcity of paired panoramic editing data, we train
a dedicated ERP-native controllable generator that synthesizes objects directly
in the equirectangular domain under user-defined conditions, enabling scalable p
aired data construction for learning diverse editing behaviors. Extensive experi
ments on our new benchmark, PEBench, demonstrate that World Shaper achieves supe
rior geometric consistency, editing fidelity, and text controllability compared
to state-of-the-art methods, enabling coherent and flexible 360° visual world cr

eation with unified editing control. Code, models, and data are available at the project page: https://world-shaper-project.github.io/.

Design-Based Anytime-Valid Inference for Randomized Experiments with Delayed Outcomes and Staggered Entry
Michael Lindon, Nathan Kallus
Delayed outcomes are ubiquitous in online experimentation: treatment can affect whether an outcome occurs, when it occurs, and its realized value.
To accommodate staggered entry while remaining robust to environmental nonstationarity and unit-level heterogeneity, we adopt a design-based perspective and target the sample cumulative reward in each arm as a function of calendar time.
Our confidence sequences allow practitioners to continuously monitor the counterfactual incremental reward, such as revenue, that would have been realized by calendar time t had all entered units been assigned to treatment rather than control.
The main technical challenge is the choice of design-based filtration, complicated by the presence of asynchronous potential outcome times.
We show that the IPW treatment-effect estimation error is not a martingale with respect to any filtration, while each arm-specific IPW estimation error is a martingale with respect to a carefully chosen arm-specific event-time filtration.
We therefore construct a confidence sequence for the treatment effect by combining two arm-level confidence sequences with a union bound, and further demonstrate that this can outperform the traditional design-based variance upper bound.
Finally, we characterize the class of augmentations for which the per-arm AIPW estimation error remains a martingale.

Reasoning about Reasoning: BAPO Bounds on Chain-of-Thought Token Complexity in LLMs
Kiran Tomlinson, Tobias Schnabel, Adith Swaminathan, Jennifer Neville
Inference-time scaling via chain-of-thought (CoT) reasoning is a major driver of state-of-the-art LLM performance, but it comes with substantial latency and compute costs. We address a fundamental theoretical question: *how many* reasoning tokens are required to solve a problem as input size grows? By extending the bounded attention prefix oracle (BAPO) model--an abstraction of LLMs that quantifies the information flow required to solve a task--we prove lower bounds on the CoT tokens required for three canonical BAPO-hard tasks: binary majority, triplet matching, and graph reachability. We show that each requires $\Omega(n)$ reasoning tokens when the input size is n. We complement these results with matching or near-matching upper bounds via explicit constructions. Finally, our experiments with frontier reasoning models show approximately linear reasoning token scaling on these tasks and failures when constrained to smaller reasoning budgets, consistent with our theoretical lower bounds. Together, our results identify fundamental bottlenecks in inference-time compute through CoT and offer a principled tool for analyzing optimal reasoning length.
****
Improving LLM-Based Recommenders with Conservative Generative Flow Networks
Xuan Yu, Feng Niu, Rui Zhu, Yudong Zhang, Xu Wang, Yang Wang
Generative Flow Networks (GFlowNets) have recently been used to improve diversity and mitigate popularity bias in LLM-based recommender systems, yet most objectives are developed under online-style assumptions. In offline LLM-based recommendation, learning is constrained to a fixed logged dataset, yielding partial support over token transitions on the dataset-induced token-prefix DAG. Naively applying Sub-Trajectory Balance (SubTB) becomes non-identifiable and can arbitrarily allocate probability mass to unsupported regions. We formalize this failure and identify three sources of non-identifiability that induce distributional shift between the dataset-implied policy and the learned policy: (i) flow overestimation, (ii) forward mass leakage, and (iii) backward compensation. To address it, we propose CFlower, which introduces a conservative SubTB objective that explicitly penalizes unsupported forward flow mass, and combines it with dataset-constrained policy learning with on-policy sampling on the dataset-induced DAG for effi

cient training under offline constraints. Experiments on three Amazon recommenda tion datasets show that CFlower improves distributional matching and delivers a stronger accuracy--exposure trade-off than prior GFlowNet and SFT baselines, whi le serving as a more reliable reference policy for downstream RL fine-tuning.
****

Variable Clustering via Distributionally Robust Nodewise Regression
Kaizheng Wang, Xiao Xu, XUNYU ZHOU
We study a multi-factor block model for variable clustering and connect it to re gularized subspace clustering through a distributionally robust version of nodew ise regression. To solve the latter problem, we derive a convex relaxation, prov ide a data-driven approach for selecting the size of the robust region, and deve lop an ADMM algorithm for efficient implementation. We validate our method in ex tensive numerical studies and demonstrate its superior performance.

ReVSI: Rebuilding Visual Spatial Intelligence Evaluation for Accurate Assessment of VLM 3D Reasoning
Yiming Zhang, Jiacheng Chen, Jiaqi Tan, Yongsen Mao, Wenhu Chen, Angel X Chang
Current evaluations of spatial intelligence can be systematically invalid under modern vision-language model (VLM) settings. First, many benchmarks derive quest ion-answer (QA) pairs from point-cloud-based 3D annotations originally curated f or traditional 3D perception. When such annotations are treated as ground truth for video-based evaluation, reconstruction and annotation artifacts can miss obj ects that are clearly visible in the video, mislabel object identities, or corru pt geometry-dependent answers (e.g., size), yielding incorrect or ambiguous QA p airs. Second, evaluations often assume full-scene access, while many VLMs operat e on sparsely sampled frames (e.g., 16-64), making many questions effectively un answerable under the actual model inputs.
We improve evaluation validity by introducing ReVSI, a benchmark and protocol th at ensures each QA pair is answerable and correct under the model's actual input s. To this end, we re-annotate object labels and geometry across 413 scenes from 5 datasets to improve data quality, and regenerate all QA pairs with rigorous b ias mitigation and human verification using professional 3D visualization and an notation tools. We further enhance evaluation controllability by providing varia nts across multiple frame budgets (16/32/64/all) and fine-grained object visibil ity metadata, enabling controlled diagnostic analyses. Evaluations of general an d domain-specific VLMs on ReVSI reveal systematic failure modes that are obscure d by prior benchmarks, yielding a more reliable and diagnostic assessment of spa tial intelligence.

Activation-Free Backbones for Image Recognition: Polynomial Alternatives within MetaFormer-Style Vision Models
Jeffrey Wang, Jonathan Gregory, Grigorios Chrysos
Modern vision backbones treat pointwise activations (e.g., ReLU, GELU) and expon ential softmax as essential sources of nonlinearity, but we demonstrate they are not required within MetaFormer-style vision backbones. We design activation-fre e polynomial alternatives for three core primitives (MLPs, convolutions, and att ention), where Hadamard products replace standard nonlinearities to yield polyno mial functions of the input. These modules integrate seamlessly into existing ar chitectures: instantiated within MetaFormer, a modular framework for vision back bones, our PolyNeXt models match or exceed activation-based counterparts across model scales on ImageNet classification, ADE20K semantic segmentation, and out-o f-distribution robustness. We also substantially outperform prior polynomial net works at reduced computational cost, showing that polynomial variants of standar d modules beat complex custom architectures. Our code is available at https://gi thub.com/jjwang8/PolyNeXt.

SE(3)-Equivariant Flow Matching with Gaussian Process Priors for Geometric Traje ctory Prediction
Xuyang Wang, Xinzhe Zhou, Xiaoming Duan, Jianping He
The trajectory prediction of N-body systems is of great significance and remains

challenging with broad applications across various fields such as physics, chemistry and biology.
Recent advances in generative models including flow matching and diffusion models have emerged as effective solutions to this problem, owing to their capacity to model the stochasticity and underlying distributions of complex system trajectories.
However, existing approaches typically adopt trivial prior distributions that neglect the temporal correlations and spatial symmetries of N-body trajectories, which not only complicates the generation process but also limits model performance.
To address these limitations, we propose GP-EquiFlow, an SE(3)-equivariant flow matching model incorporating vector-valued Gaussian processes.
Based on observed trajectories, we employ vector-valued Gaussian processes to construct SE(3)-equivariant prior distributions, which exhibit enhanced consistency with the target data distribution in both spatial and temporal dynamics.
Extensive experiments on N-body simulations and molecular dynamics demonstrate that the proposed GP-EquiFlow delivers more accurate predictions while requiring fewer sampling steps, underscoring the effectiveness of integrating Gaussian process-based SE(3)-equivariant prior distributions in geometric trajectory prediction.

Polaris: Coupled Orbital Polar Embeddings for Hierarchical Concept Learning
Sahil Mishra, Srinitish Srinivasan, Sourish Dasgupta, Tanmoy Chakraborty
Real-world knowledge is often organized as hierarchies such as product taxonomies, medical ontologies, and label trees, yet learning hierarchical representations is challenging due to asymmetric structure and noisy semantics. We introduce Polaris, a polar hyperspherical embedding framework that separates semanticity from hierarchy using angular geometry and radius, enabling the learning of meaning and structure without interference. To map latent representation onto the sphere, we project it to the tangent space at the north pole, apply the exponential map, and learn unit-norm representations using spherical linear layers. Polaris then combines robust local constraints, global regularization that prevents geometric collapse, and uncertainty-aware asymmetric objectives that encourage directional containment. At inference time, Polaris uses structure-guided retrieval to efficiently narrow down candidate parents before final ranking. We evaluate Polaris on different settings of taxonomy expansion -- spanning trees, multi-parent DAGs, and multimodal hierarchies, showing consistent improvements of up to $\sim$19 points in top-K retrieval and up to $\sim$ 60\% reduction in mean rank over fourteen strong baselines.

Predicting Future Utility: Global Combinatorial Optimization for Task-Agnostic KV Cache Eviction
Ziyao Tang, Pengkun Jiao, Xinhang Chen, Wei Liu, Shiyong Li, Jingjing Chen
Given the quadratic complexity of attention, KV cache eviction is vital to accelerate model inference.
Current KV cache eviction methods typically rely on instantaneous heuristic metrics, implicitly assuming that score magnitudes are consistent proxies for importance across all heads.
However, this overlooks the heterogeneity in predictive fidelity across attention heads. While certain heads prioritize the instantaneous contribution of tokens, others are dedicated to capturing long-horizon utility.
In this paper, we propose that optimal budget allocation should be governed by the marginal utility in preserving long-term semantic information.
Building on this insight, we propose LU-KV, a novel framework that formulates head-level budget allocation as a global combinatorial optimization problem to maximize the long-horizon marginal contribution of reserved tokens. To solve this non-convex problem, we employ a convex-hull relaxation and a marginal-utility-based greedy solver, achieving near-optimal solutions. Furthermore, we implement a data-driven offline profiling protocol to facilitate the practical deployment of LU-KV.

Evaluations on LongBench and RULER benchmarks demonstrate that LU-KV reduces KV cache size by 80\% with minimal performance degradation, while also decreasing inference latency and GPU memory footprint.

Mining Tensor/Neuron-Level Sparsity to Maximize Mixture-of-Experts Potential in Post-Training and Inference
Weilin Cai, Le Qin, Shwai He, Junwei Cui, Ang Li, Jiayi Huang
Mixture of Experts (MoE) has emerged as a mainstream architecture for Large Language Models (LLMs), balancing computational efficiency with model scalability. While prior work has explored increasing tensor-level sparsity via finer-grained expert configurations during pre-training, we identify significant unexploited sparsity at both the tensor and neuron levels during post-training and inference. To leverage this, we propose complete expert partition for post-training and threshold-based token-expert dropping for inference. These techniques improve the Mixtral-8$\times$7B model's average accuracy by 1\% across nine downstream benchmarks (notably 4\% on GSM8K).
To further optimize the accuracy-efficiency trade-off for inference, we introduce dual-threshold token-expert dropping with partial expert partition and reconstruction. Our approach yields a 1.19$\times$ MoE speedup and a 0.5\% accuracy gain on Mixtral-8$\times$7B when combining post-training and inference optimizations. For inference-only optimization on OLMoE-Instruct and DeepSeek-V2-Lite-Chat, we achieve up to 1.41$\times$ MoE speedup with a negligible accuracy loss ($<$0.5\%).
****

GLEAN: Guideline-Grounded Evidence Accumulation for High-Stakes Agent Verification
Yichi Zhang, Nabeel Seedat, Yinpeng Dong, Peng Cui, Jun Zhu, Mihaela van der Schaar
As LLM-powered agents have been used for high-stakes decision-making, such as clinical diagnosis, it becomes critical to develop reliable verification of their decisions to facilitate trustworthy deployment. Yet, existing verifiers usually underperform owing to a lack of domain knowledge and limited calibration. To address this, we establish **GLEAN**, an agent verification framework with **G**uide**L**ine-grounded **E**vidence **A**ccumulatio**N** that compiles expert-curated protocols into trajectory-informed, well-calibrated correctness signals. GLEAN evaluates the step-wise alignment with domain guidelines and aggregates multi-guideline ratings into surrogate features, which are accumulated along the trajectory and calibrated into correctness probabilities using Bayesian logistic regression. Moreover, the estimated uncertainty triggers active verification, which selectively collects additional evidence for uncertain cases via expanding guideline coverage and performing differential checks. We empirically validate GLEAN with agentic clinical diagnosis across three diseases from the MIMIC-IV dataset, surpassing the best baseline by 12\% in AUROC and 50\% in Brier score reduction, which confirms the effectiveness in both discrimination and calibration. In addition, the expert study with clinicians recognizes GLEAN's utility in practice.

Investigating Component Contributions in Multi-Agent ML Systems
Junsung Kim, Ilia Mireskandari, Seungwan Son, Yifan Zhou, Khizer Shahid, Dylan Yihan Dai
Autonomous agents for machine learning engineering have advanced rapidly, yet comparing their effectiveness remains difficult. Existing systems combine different techniques---multi-agent decomposition, iterative refinement, memory management, and planning---in varying configurations, making it unclear which components actually drive performance. Complicating evaluation, existing benchmarks rely on historical competitions whose data likely contaminates LLM training corpora and whose static baselines reflect outdated human performance. To address this, we conduct over 4,000 controlled experiments systematically ablating architectural components, alongside K-live, a new benchmark of 25 active competitions that provides a contamination-free, dynamic evaluation environment. Our findings challenge common design assumptions: iterative feedback contributes more than architect

ural complexity, and multi-agent coordination can hurt as often as it helps. The se results provide concrete guidance for practitioners building ML engineering a gents.

Predicting evolutionary rate as a pretraining task improves genome language mode l representations

Micaela Elisa Consens, Kevin K Yang, James Brian Hall, Ashley Mae Conard, BO WAN G, Lorin Crawford, Alan M Moses, Alex Xijie Lu

Genome language models (gLM) have the potential to further understanding of regu latory genomics without requiring labeled data. Most gLMs are pretrained using s equence reconstruction tasks inspired by natural language processing, but recent studies have shown that these gLMs often fail to capture biological signal. To overcome this, we introduce pretraining tasks that predict the rate of evolution . These tasks are designed so that they can be composed with sequence reconstruc tion, enabling a controlled comparison of predicting sequence only, evolutionary rate only, or both. To address gaps in existing evaluations, we developed a sui te of biologically grounded benchmarks.

Across these tasks, and for established variant effect prediction benchmarks, mo dels pretrained on both sequence and evolutionary rate outperform those trained on sequence alone, and training on evolutionary rate can make the even the relat ively small models in our work competitive with much larger existing gLMs for so me tasks on the human genome. These results establish evolution as a key trainin g target for genome-scale models.

Regret Pre-training: Bridging Prior and Posterior Views for Enhanced Knowledge G rounding

Mingkuan Zhao, Xiayu Sun, Wentao Hu, Suquan Chen, Jiaxuan Li, Xiaoyan Zhu, Xin L ai, Jiayin Wang

Causal language models factorize sequence probabilities using only preceding con text, leaving future information unexploited during training despite its availab ility in the training data. This paper introduces Regret Pre-training, a self-su pervised framework grounded in the Learning Using Privileged Information (LUPI) paradigm. The framework employs a dual-view architecture in which a single model generates both a causal Student distribution and a future-conditioned Teacher d istribution. The training objective augments standard language modeling with a r egret loss that minimizes the KL divergence from teacher to student, transferrin g future-aware signals to the causal representations. We investigate two teacher configurations on the OLMoE-1B-7B architecture:LocalRegret, which extends atten tion by one future token, andGlobalRegret, which conditions on bidirectional con text with the target position masked. Experiments on nine downstream tasks follo wing 4 billion tokens of training demonstrate that both configurations consisten tly outperform the baseline. On average,GlobalRegret andLocalRegret achieve 33.9 % and 32.2% accuracy respectively, surpassing the baseline's 30.2%. Most notably ,GlobalRegret improves BoolQ performance by 18.1 percentage points (61.0% vs 42. 9%). The framework introduces no additional parameters and requires only one ext ra inference-mode forward pass per training step.

ExVerus: Verus Proof Repair via Counterexample Reasoning

Jun Yang, Yuechun Sun, Yi Wu, Rodrigo Caridad, Yongwei Yuan, Jianan Yao, Shan Lu , Kexin Pei

Large Language Models (LLMs) have shown promising results in automating formal v erification. However, existing approaches treat proof generation as a static, en d-to-end prediction over source code, relying on limited verifier feedback and l acking access to concrete program behaviors. We present ExVerus, a counterexampl e-guided framework that enables LLMs to reason about proofs using behavioral fee dback via counterexamples. When a proof fails, ExVerus automatically generates a nd validates counterexamples, and then guides the LLM to generalize them into in ductive invariants to block these failures. Our evaluation shows that ExVerus si gnificantly improves proof accuracy, robustness, and token efficiency over the s tate-of-the-art prompting-based Verus proof generator.

****
SE(n)-Invariant Flow Matching: A General Framework with Application to Object Reassembly
Gaël Heck, Sylvie Le Hégarat-Mascle, Nicolas Lermé
Reassembling N fragments in n-dimensional space is a shape reconstruction task that is invariant to global rigid motions.
Training directly on $\mathcal{M}=\mathrm{SE}(n)^N$ can be ill-posed: standard losses penalize solutions that differ only by a global transform.
Existing methods often address this with ad-hoc anchoring which breaks permutation invariance across fragments and can introduce biases that must be mitigated with extensive and costly data augmentation.
We propose a geometric framework that enforces invariance by construction. First, a **Global Gauge Fixing** (GGF) strategy deterministically aligns configurations using an intrinsic generalized-inertia rule.
Second, we introduce a **quotient-invariant Flow Matching objective** that operates via orthogonal projection onto the horizontal tangent bundle. This construction factors out global pose at each timestep, enabling the model to learn only shape-changing dynamics on the quotient space $\mathcal{M}/\mathrm{SE}(n)$.
Our unified $\mathrm{SE}(n)$-invariant framework admits efficient closed-form 2D/3D instantiations and improves accuracy on polygonal jigsaw puzzles and 3D fracture reassembly benchmarks.
****
HELIX: Hybrid Encoding with Learnable Identity and Cross-dimensional Synthesis for Time Series Imputation
Fengming Zhang, Wenjie Du, Huan Zhang, Ke Yu, Shen Qu
Time series imputation benefits from leveraging cross-feature correlations, yet existing attention-based methods re-discover feature relationships at each layer, lacking persistent anchors to maintain consistent representations. To address this, we propose HELIX, which assigns each feature a learnable feature identity, a persistent embedding that captures intrinsic semantic properties throughout the network. Unlike graph-based methods that rely on predefined topology and assume homogeneous spatial relationships, HELIX learns arbitrary feature dependencies end-to-end from temporal co-variation, naturally handling datasets where features mix spatial locations with semantic variables. Integrated with hybrid temporal-feature attention, HELIX achieves the state-of-the-art performance, surpassing all 16 baselines on 5 public datasets across 21 experimental settings in our evaluation. Furthermore, our mechanistic analysis reveals that HELIX aligns learned feature identities and dependencies with latent physical and semantic structure progressively across layers, demonstrating that it more effectively translates cross-feature structure into imputation accuracy.

Manifold-Aligned Guided Integrated Gradients for Reliable Feature Attribution
Soyeon Kim, Seongwoo Lim, Kyowoon Lee, Jaesik Choi
Feature attribution is central to diagnosing and trusting deep neural networks, and Integrated Gradients (IG) is widely used due to its axiomatic properties. However, IG can yield unreliable explanations when the integration path between a baseline and the input passes through regions with noisy gradients. While Guided Integrated Gradients reduces this sensitivity by adaptively updating low-gradient-magnitude features, input-space guidance still produces intermediate inputs that deviate from the data manifold. To address this limitation, we propose **Manifold-Aligned Guided Integrated Gradients** (MA-GIG), which constructs attribution paths in the latent space of a pre-trained variational autoencoder. By decoding intermediate latent states, MA-GIG biases the path toward the learned generative manifold and reduces exposure to implausible input-space regions. Through qualitative and quantitative evaluations, we demonstrate that MA-GIG produces faithful explanations by aggregating gradients on path features proximal to the input. Consequently, our method reduces off-manifold noise and outperforms prior path-based attribution methods across multiple datasets and classifiers. Our code is available at https://github.com/leekwoon/ma-gig/.

OC-space: a Unifying Perspective on Verification of Tree Ensembles
Timo Martens, Laurens Devos, Lorenzo Cascioli, Wannes Meert, Hendrik Blockeel, J esse Davis
We study the problem of verifying whether certain properties such as robustness or fairness hold in an ensemble of decision trees.
This problem is known to be NP-hard, with most research targeting a solution to a specific verification task. We explore the problem through the lens of an ens emble's OC-space: the set of all possible combinations of the individual trees' predictions. This provides a unifying view that yields a more generic and flexib le approach to verification.
We show that a wide variety of existing verification tasks can be (1) framed as simple searches through OC-space, and
(2) answered in time linear or quadratic in the size of the OC-space.
Moreover, the search can be made more efficient by using spatial index structure s. Interestingly, while the OC-space can grow exponentially with the ensemble's size, in practice it is often feasible to enumerate all output configurations. E mpirically, we show that our generic approach can be faster than approaches targ eting a single verification task.

Steering Beyond the Support: Adversarial Training on Unsupervised Jailbroken Act ivation Simulation
LUOYU CHEN, Weiqi Wang, Zhiyi Tian, Chenhan Zhang, Feng Wu, Jianhuan Huang, Ahme d Asiri, Shui Yu
Jailbreak prompts can trigger harmful completions on aligned LLMs, In accordance , safety steering has been proposed: test-time activation interventions that ste er jailbreak activations to trigger refusal while preserving benign utility. How ever, existing steering methods are fundamentally supervised and tied to a stati c, limited training set, whereas real jailbreaks evolve and are often out-of-dis tributed from the training set, leading to failures on unseen attacks. In this p aper, we tackle this failure by developping a \emph{zero-shot} defense. Base on unsupervised latent direction discovery, we directly simulate jailbroken activat ions without any knowledge of jailbreak strategy. To build a defense mechnism up on this, we propose a bi-level adversarial training framework. In the inner step , we simulate diverse jailbroken activations by extrapolating from refusal state harmful-request activations via unsupervised latent direction discovery. In the outer step, we train a potential-induced steering field to push these adversari al jailbroken states into refusal regions while keeping benign unchanged. Across three LLMs and six classical jailbreak families, our method achieves strong def ense with attack success rates mostly below 5%, and we analyzed the increasing s ubspace coverage of our simulated jailbroken activations on real jailbreaks thro ughout training, which helps explain the increasing robustness of our defense me chnism.

3D MeanFlow: One-Step Point Cloud Completion and Generation via Average-Velocity Transport
Haowen Zhong, Jiujun Cheng, Haowen Wang, Chao Wei, Lu Yang, Qichao Mao, Shangce Gao
Point cloud completion and generation are important across many 3D tasks, where both fidelity and sampling efficiency matter. Prevailing high-fidelity approache s rely on long sampling schedules, which incur substantial inference latency. Fe w-step alternatives typically use rectification or distillation, leading to mult i-stage training pipelines and potential quality trade-offs. We present 3D MeanF low (3DMF), a distillation-free model that performs one-step average-velocity tr ansport for point cloud completion and generation. We optimize an instantaneous- average consistency objective and impose a shape-level constraint to stabilize t raining. Additionally, we introduce PointPlug, integrating completion into 3D ob ject detectors and evaluating its impact. PointPlug uses adaptive selection that balances benefit and latency. Across standard benchmarks, 3DMF achieves one-ste p sampling with an order-of-magnitude speedup while maintaining competitive fide lity. On nuScenes and KITTI, inserting PointPlug improves all evaluated detector

s under comparable settings.
****
EquiCAD: A Geometric Equivariant Neural Network for 3D Shape Classi■cation
Yonghao Su, Yantao Gan, Junfeng Long, Caiyang Yu, Wenhao Zheng, Jiancheng Lv, Xianggen Liu
Three-dimensional (3D) shape classification plays a central role in computer vision and computer-aided design (CAD), underpinning applications in intelligent manufacturing, automated inspection, and digital engineering. Despite recent progress with 3D CNNs and graph-based approaches, existing methods often overlook the geometric-topological regularities and symmetry principles intrinsic to CAD boundary representations (B-reps). To address this challenge, we introduce EquiCAD, a symmetry-aware learning framework that integrates equivariant representations with graph-based reasoning. By leveraging group-theoretic decomposition of curve and surface descriptors, EquiCAD preserves symmetry-consistent feature transformations while retaining rich geometric details. The model further exploits hierarchical message passing to capture interactions between local features and global structure. Experimental results across multiple datasets, including SolidLetters, Parts, the Machining Feature benchmark, and our newly constructed Features dataset, demonstrate substantial improvements over prior state-of-the-art approaches, particularly on industrially relevant shapes with fine-grained attributes. These findings highlight the value of symmetry-aware modeling for robust and generalizable 3D shape analysis.
****
Universal Learning of Nonlinear Dynamics
Evan Dogariu, Anand Paresh Brahmbhatt, Elad Hazan
We study the fundamental problem of one-step prediction of a marginally stable unknown nonlinear dynamical system. We describe an algorithm for this problem, based on the technique of spectral filtering, which learns a mapping from past observations to the next based on a spectral representation of the system. Using techniques from online convex optimization, we prove vanishing prediction error for any nonexpansive nonlinear dynamical system with finitely many marginally stable modes, with rates governed by a novel quantitative control-theoretic notion of learnability. The main technical component of our method is a new spectral filtering algorithm for linear dynamical systems, which incorporates past observations and applies to general noisy and marginally stable systems. This generalizes the original spectral filtering algorithm to both asymmetric dynamics as well as incorporating noise correction, and is of independent interest.

Beyond Structural Symmetries: Linear Mode Connectivity via Neuron Identifiability
Vincent Bürgin, Daniel Herbst, Ya-Wei Eileen Lin, Stefanie Jegelka
Many striking phenomena in deep learning, such as linear mode connectivity and the structured behavior of training dynamics, are closely tied to parameter symmetries: transformations that leave the realized function unchanged. Despite growing attention to parameter symmetries, the exact interplay between parameters, data, and representations remains underexplored. To investigate this, we develop a theoretical framework of effective function classes, i.e., the set of functions a neuron can realize on its input support, and the norm cost of realizing them. We then formalize *effective symmetry breaking* via neuron identifiability across independent training runs. Our analysis shows that neural networks can admit large families of approximately equivalent solutions even in *structurally asymmetric* models. We further show that neuron identifiability enables representation merging *without prior alignment*, and characterize when such merging admits a linear low-loss path. These findings highlight the role of effective function classes in affecting the loss landscape.
****
StructMAR: Structure-Aware Masked Autoregression for Explicit Layout Alignment in Text-to-Image Generation
Gang Cao, Junying Zhang
Although text-to-image generation has achieved significant progress, strict inst

ance-level layout alignment remains a challenge for many applications. Masked Au toregressive (MAR) models on continuous latents are both efficient and high-fide lity, yet the standard practice of flattening 2D latents into 1D sequences weake ns spatial topology, limiting precise controllability. To address this, we propo se StructMAR, a structure-aware masked autoregressive framework that transforms layout alignment from a soft correlation into an explicit structural alignment. By integrating 2D Rotary Positional Embeddings with a Layout-Guided Attention Bi as, StructMAR explicitly biases latent tokens toward their corresponding layout instances during attention computation. We further use Group Relative Policy Opt imization (GRPO) as a final-stage policy refinement to reduce the mismatch betwe en the MAR training objective and detector-based layout evaluation metrics. Eval uated on the COCO-Position and COCO-MIG benchmarks, StructMAR achieves state-of- the-art performance, reaching 57.2 AP and 79.4 mIoU on the former, and 61.7 ISR and 56.9 mIoU on the latter. These results, coupled with a 4.05$\times$ inferenc e speedup, underscore the efficacy of explicit structural inductive biases in co ntrollable autoregressive generation.

Hard Labels In! Rethinking the Role of Hard Labels in Mitigating Local Semantic Drift

Jiacheng Cui, Bingkui Tong, Xinyue Bi, Xiaohan Zhao, Jiacheng Liu, Zhiqiang Shen

Soft labels from teacher models are a de facto practice for knowledge transfer a nd large-scale dataset distillation (e.g., SRe^{2}L, LPLD). However, when we lim it the number of crops per image to reduce the substantial cost of storing preco mputed soft labels, these methods suffer severely from local semantic drift: vis ually ambiguous crops can cause soft supervision to deviate from the image-level ground-truth semantics, leading to persistent errors and a train–test distribut ion mismatch. We revisit the overlooked role of hard labels and show that, when properly integrated, they can act as a content-invariant semantic anchor that ca librates such drift. We theoretically analyze the emergence of drift under spars e soft-label supervision and demonstrate that hybridizing hard and soft labels r estores alignment between visual content and semantic supervision. Building on t his insight, we propose a new training paradigm, Hard Label for Alleviating Loca l Semantic Drift (HALD), which uses hard labels as intermediate corrective signa ls while preserving the fine-grained benefits of soft labels. Extensive experime nts on dataset distillation and large-scale classification benchmarks show consi stent generalization improvements. On ImageNet-1K, our method achieves 42.7% acc uracy with only 285M soft-label storage (reduces by 100$\times$), outperforming prior state-of-the-art LPLD by 9.0%. Code is available at https://github.com/Jia cheng8/HALD.

Bridging Your Imagination with Audio-Video Generation via a Unified Director

Jiaxu Zhang, Tianshu Hu, Yuan Zhang, Zenan Li, Linjie Luo, Mingyuan Gao, Guoshen g Lin, Xin Chen

Existing AI-driven video creation systems typically treat script drafting and ke y-shot design as two disjoint tasks: the former relies on large language models, while the latter depends on image generation models. We argue that these two ta sks should be unified within a single framework, as logical reasoning and imagin ative thinking are both fundamental qualities of a film director. In this work, we propose **UniMAGE**, a unified director model that bridges user prompts with well-structured scripts, thereby empowering non-experts to produce long-context, multi-shot films by leveraging existing audio–video generation models. To achie ve this, we employ the Mixture-of-Transformers architecture that unifies text an d image generation. To further enhance narrative logic and keyframe consistency, we introduce a ``first interleaving, then disentangling" training paradigm. Spe cifically, we first perform **Interleaved Concept Learning**, which utilizes int erleaved text–image data to foster the model’s deeper understanding and imaginat ive interpretation of scripts. We then conduct **Disentangled Expert Learning**, which decouples script writing from keyframe generation, enabling greater flexi bility and creativity in storytelling. Extensive experiments demonstrate that Un iMAGE achieves state-of-the-art performance among open-source models, generating

logically coherent scripts and visually consistent keyframe images.

Preserve-Then-Quantize: Balancing Rank Budgets for Quantization Error Reconstruction in LLMs
Yoonjun Cho, Dongjae Jeon, Soeun Kim, Moongyu Jeon, Albert No
Quantization Error Reconstruction (QER) reduces accuracy loss in Post-Training Quantization (PTQ)
by approximating weights as $\mathbf{W} \approx \mathbf{Q} + \mathbf{L}\mathbf{R}$, using a rank-$r$ correction to reconstruct quantization error.
Prior methods devote the full rank budget to error reconstruction,
which is suboptimal when $\mathbf{W}$ has intrinsic low-rank structure and quantization corrupts dominant directions.
We propose Structured Residual Reconstruction (SRR),
a rank-allocation framework that preserves the top-k singular subspace of the activation-scaled weight before quantization,
quantizes only the residual, and uses the remaining rank $r-k$ for error reconstruction.
We derive a theory-guided criterion for selecting k by balancing quantization-exposed energy
and unrecoverable error under rank constraints.
We further show that resulting $\mathbf{Q}+\mathbf{L}\mathbf{R}$ parameterization naturally supports Quantized Parameter-Efficient Fine-Tuning (QPEFT),
and stabilizes fine-tuning via gradient scaling along preserved directions.
Experiments demonstrate consistent perplexity reductions across diverse models and quantization settings in PTQ,
along with a 5.9 percentage-point average gain on GLUE under 2-bit QPEFT.
The project page is available at https://ai-isl.github.io/srr.

OpenTSLM: Time-Series Language Models for Reasoning over Multivariate Medical Text- and Time-Series Data
Patrick Langer, Thomas Kaar, Max Rosenblattl, Maxwell A Xu, Winnie Chow, Martin Maritsch, Robert Jakob, Ning Wang, Juncheng Liu, Aradhana Verma, Brian Han, Daniel Seung Kim, Henry Chubb, Scott R. Ceresnak, Aydin Zahedivash, Alexander T Sandhu, Fatima Rodriguez, Daniel McDuff, Elgar Fleisch, Oliver Oppers Aalami, Filipe Barata, Paul Schmiedmayer
Large Language Models have shown strong capabilities in interpreting multimodal data but remain limited in handling time-series data. Addressing this gap could help to translate longitudinal and wearable data into actionable insights and patient-facing digital health applications.
We propose OpenTSLM, an open-source family of Time Series Language Models integrating time-series as a native modality into pretrained LLMs, enabling natural-language prompting and reasoning over multiple time-series via either soft prompting (OpenTSLM-SoftPrompt) or cross-attention (OpenTSLM-Flamingo).
To enable training models for time-series reasoning, we introduce three datasets: HAR-CoT (human activity recognition), Sleep-CoT (sleep staging), and ECG-QA-CoT (electrocardiogram question answering).
Across tasks, OpenTSLM models outperform baselines, reaching F1 scores of 69.88% in sleep staging and 67.64% in HAR; OpenTSLM-Flamingo also scales more efficiently in memory as the number and length of time series increase.
Expert evaluations with cardiologists show that OpenTSLMs exhibit strong reasoning capabilities on raw ECG data.

From Optimization to Generalization under Heavy-Tailed Data: The Role of Gradient Clipping
Aleksandr Shestakov, Martin Taká■, Eduard Gorbunov
Gradient clipping is widely used to stabilize stochastic gradient methods and is often theoretically motivated by heavy-tailed gradient noise, where even second moments may be infinite, seemingly contradicting the finite-sum ERM setting, where all empirical moments are finite once the dataset is fixed. We resolve this paradox by explicitly separating data sampling from optimization randomness: alt

hough moments are finite conditional on the dataset, heavy-tailed data induce da taset-dependent noise whose second moment typically grows with the dataset size N. In particular, when $\|\nabla f(x_\star,\xi)\|$ has tail index $\alpha \in (1,2)$, the quantity $\frac{1}{N}\sum_{i=1}^N\|\nabla f(x_\star,\xi_i)\|^2$ scal es as $N^{\frac{2}{\alpha}-1}$, leading to deteriorating convergence guarantees for standard SGD as N increases. In contrast, we show that SGD with clipping a voids this growth and admits finite-sum convergence guarantees under heavy-taile d data for broad step-size and clipping schedules. We further derive generalizat ion bounds for strongly convex smooth objectives and show that the tail behavior of gradients at the population minimizer is the key quantity linking optimizati on and generalization under heavy-tailed data.

When Sample Selection Bias Precipitates Model Collapse

Xinbao Qiao, Xianglong Du, Wei Liu, Jingqi Zhang, Peihua Mai, Meng Zhang, Yan Pa ng

The proliferation of recursive training on synthetic data can alleviate data sca rcity but risks model collapse, where repeated training erodes distributional ta ils and homogenizes outputs. Data selection is widely viewed as a remedy, yet it s reliability depends critically on the reference distribution used by the verif ier. We show that in low-resource verification regimes, where each verifier obse rves only a small, fragmented, and biased slice of the target manifold, selectio n itself becomes biased. This situation naturally arises in low-resource data si los such as healthcare consortia or proprietary financial institutions, where ra w data cannot be pooled and local references are inherently incomplete. As a res ult, selection preferentially retains samples aligned with the local manifold wh ile pruning globally relevant tail modes, turning from a safeguard against colla pse into a mechanism that precipitates it. We theoretically prove that such silo ed selection accelerates collapse and induces power-law diversity decay. As an i nitial mitigation, we construct Wasserstein proxy references from multiple silos without sharing raw data. Empirical results confirm that local-reference select ion fails on skewed distributions, whereas collaborative proxy references mitiga te diversity degradation, suggesting that recursive synthetic-data pipelines req uire particular caution when real-data coverage is fragmented or scarce.

Distinguishable Deletion: Unifying Knowledge Erasure and Refusal for Large Langu age Model Unlearning

Puning Yang, Junchi Yu, Qizhou Wang, Philip Torr, Bo Han, Xiuying Chen

Mitigating sensitive and harmful outputs is fundamental to ensuring safe deploym ent of LLMs.

Existing approaches typically follow two paradigms: Knowledge Deletion (KD), whi ch erases undesirable information during training, and Distinguishable Refusal (DR), which steers models away from using sensitive knowledge during inference.

Despite rapid progress, KD-based unlearning struggles with biased deletion due t o suppressing specific token sequences as a substitute for complete knowledge re moval, whereas DR-based unlearning risks the re-emergence of harmful knowledge b ecause the underlying knowledge remains intact.

To address these issues, we propose Distinguishable Deletion ($\mathrm{D^2}$), a paradigm that restricts the response distribution in the latent representation rather than specific tokens to erase undesirable knowledge, while distinguishing it from retained knowledge, enabling a refusal mechanism to handle unlearned in puts safely and coherently.

To implement $\mathrm{D^2}$, we introduce an energy index that quantifies the pr esence of knowledge and the separation between unlearned and retained content.

Mathematical and empirical analyses show that energy is both accurate and effici ent, enabling Energy-based Unlearning Alignment (EUA) to enforce energy-boundary unlearning during training and apply an energy-based refusal mechanism at infer ence.

Extensive experiments demonstrate that EUA significantly outperforms previous me thods, indicating the superiority of $\mathrm{D^2}$.

Our code is available at https://github.com/Puning97/EUA-for-LLM-Unlearning.

Decomposing the Basic Abilities of Large Language Models: Mitigating Cross-Task Interference in Multi-Task Instruct-Tuning
Bing Wang, Ximing Li, Changchun Li, Jinjin Chi, Gang Niu, Masashi Sugiyama
Recently, the prominent performance of large language models (LLMs) has been largely driven by multi-task instruct-tuning. Unfortunately, this training paradigm suffers from a key issue, named cross-task interference, due to conflicting gradients over shared parameters among different tasks. Some previous methods mitigate this issue by isolating task-specific parameters, e.g., task-specific neuron selection and mixture-of-experts. In this paper, we empirically reveal that the cross-task interference still exists for the existing solutions because of many parameters also shared by different tasks, and accordingly, we propose a novel solution, namely Basic Abilities Decomposition for multi-task Instruct-Tuning (BADIT). Specifically, we empirically find that certain parameters are consistently co-activated, and that co-activated parameters naturally organize into base groups. This motivates us to analogize that LLMs encode several orthogonal basic abilities, and that any task can be represented as a linear combination of these abilities. Accordingly, we propose BADIT that decomposes LLM parameters into orthogonal high-singular-value LoRA experts representing basic abilities, and dynamically enforces their orthogonality during training via spherical clustering of rank-1 components. We conduct extensive experiments on the SuperNI benchmark with 6 LLMs, and empirical results demonstrate that BADIT can outperform SOTA methods and mitigate the degree of cross-task interference.

Beyond Mode Collapse: Distribution Matching for Diverse Reasoning
Xiaozhe Li, Yang Li, Xinyu Fang, Shengyuan Ding, Peiji Li, Yongkang Chen, Yichuan Ma, TianYi Lyu, Linyang Li, Dahua Lin, Qipeng Guo, Qingwen Liu, Kai Chen
On-policy reinforcement learning methods like GRPO suffer from \emph{mode collapse}: they exhibit reduced solution diversity, concentrating probability mass on a single solution once discovered and ceasing exploration of alternative strategies. We show this stems from reverse KL minimization's mode-seeking behavior, which reinforces the first high-reward trajectory found rather than maintaining a distribution over multiple diverse solutions. We propose DMPO (\textbf{D}istribution-\textbf{M}atching \textbf{P}olicy \textbf{O}ptimization), which prevents mode collapse through principled approximation of forward KL minimization. DMPO constructs a group-level target distribution over sampled trajectories proportional to their rewards, then aligns the policy distribution to this target. This provides mode-covering behavior without requiring sampling from the intractable global target distribution, enabling sustained exploration throughout training. We validate DMPO on NP-hard combinatorial optimization, where exponentially many feasible solutions exist but only a few approach optimality—an ideal testbed for evaluating exploration. DMPO achieves {43.9\% Quality Ratio on text-based NP-Bench (vs. GRPO's 40.1\%)} and {43.1\% on vision-based NP-Bench (vs. 38.4\%)}—demonstrating 9\% and 12\% relative improvements respectively. These gains generalize to mathematical reasoning (+2.0\%) and out-of-domain tasks (+2.3\%), showing that diversity-preserving training enhances general reasoning capabilities across modalities. Our work establishes distribution matching as a practical, principled approach to preventing mode collapse in on-policy RL, with consistent quality improvements demonstrating sustained exploration across diverse reasoning tasks.
****
Success-Conditioning as Policy Improvement: The Optimization Problem Solved by Imitating Success
Daniel Russo
A widely used technique for improving policies is success conditioning, in which one collects trajectories, identifies those that achieve a desired outcome, and updates the policy to imitate the actions taken along successful trajectories. This principle appears under many names---rejection sampling with SFT, goal-conditioned RL, Decision Transformers---yet what optimization problem it solves, if any, has remained unclear. We prove that success conditioning exactly solves a trust-region optimization problem, maximizing policy improvement subject to a $\c

hi^2$ divergence constraint whose radius is determined automatically by the data . This yields an identity: relative policy improvement, the magnitude of policy change, and a quantity we call action-influence---measuring how random variation in action choices affects success rates---are exactly equal at every state. Success conditioning thus emerges as a conservative improvement operator. Exact success conditioning cannot degrade performance or induce dangerous distribution shift, but when it fails, it does so observably, by hardly changing the policy at all. We apply our theory to the common practice of return thresholding, showing this can amplify improvement, but at the cost of potential misalignment with the true objective.

SJD-SV: Speculative Jacobi Decoding with Semantics Verification for Autoregressive Image Generation

Baoquan Zhang, Bingqi Shan, Shihao Fang, Kenghong Lin, Xutao Li, Yunming Ye

Speculative Jacobi Decoding (SJD) is an important approach for accelerating autoregressive image generation. Although SJD has shown superior performance, recent studies point out that it usually suffers from a token ambiguity issue during token verification but its reason can not be well explained. To figure out this reason, in this paper, we conduct a visualization analysis on vision token and find that different from text tokens, vision tokens generally corresponds to some local, small, and unclear vision details, which means only using single token is difficult to accurately express a certain semantic, thereby causing token ambiguity issue. To this end, we propose a novel Speculative Jacobi Decoding with Semantics Verification (called SJD-SV), for accelerating autoregressive image generation. The key idea is that leveraging the strong correction characters between tokens to recognize semantic-aware token subsequence and then instead of perform token-by-token verification, turning to perform verification on semantic-aware token subsequence level for accelerating image generation. In particular, our method is plug-in, which can be directly integrated into existing SJD and its variants. Extensive experiments on various datasets show that existing SJD methods achieve significant performance improvement after integrating our SJD-SV method .

Evidential Reasoning Advances Interpretable Real-World Disease Screening

Chenyu Lian, Hong-Yu Zhou, Jing Qin

Disease screening is critical for early detection and timely intervention in clinical practice. However, most current screening models for medical images suffer from limited interpretability and suboptimal performance. They often lack effective mechanisms to reference historical cases or provide transparent reasoning pathways. To address these challenges, we introduce EviScreen, an evidential reasoning framework for disease screening that leverages region-level evidence from historical cases. The proposed EviScreen offers retrospection interpretability through regional evidence retrieved from dual knowledge banks. Using this evidential mechanism, the subsequent evidence-aware reasoning module makes predictions using both the current case and evidence from historical cases, thereby enhancing disease screening performance. Furthermore, rather than relying on post-hoc saliency maps, EviScreen enhances localization interpretability by leveraging abnormality maps derived from contrastive retrieval. Our method achieves superior performance on our carefully established benchmarks for real-world disease screening, yielding notably higher specificity at clinical-level recall. Code is publicly available at https://github.com/DopamineLcy/EviScreen.

Image Restoration via Diffusion Models with Dynamic Resolution

Yang Zheng, Wen Li, Zhaoqiang Liu

Diffusion models (DMs) have exhibited remarkable efficacy in various image restoration tasks. However, existing approaches typically operate within the high-dimensional pixel space, resulting in high computational overhead. While methods based on latent DMs seek to alleviate this issue by utilizing the compressed latent space of a variational autoencoder, they require repeated encoder-decoder inference. This introduces significant additional computational burdens, often resul

ting in runtime performance that is even inferior to that of their pixel-space c
ounterparts. To mitigate the computational inefficiency, this work proposes proj
ecting data into lower-dimensional subspaces using dynamic resolution DMs to acc
elerate the inference process. We first fine-tune pre-trained DMs for dynamic re
solution priors and adapt DPS and DAPS, which are two widely used pixel-space me
thods for general image restoration tasks, into the proposed framework, yielding
 methods we refer to as SubDPS and SubDAPS, respectively. Given the favorable in
ference speed and reconstruction fidelity of SubDAPS, we introduce an enhanced v
ariant termed SubDAPS++ to further boost both reconstruction efficiency and qual
ity. Empirical evaluations across diverse image datasets and various restoration
 tasks demonstrate that the proposed methods outperform recent DM-based approach
es in the majority of experimental scenarios. The code is available at https://
github.com/StarNextDay/SubDAPS.git.

CoRe: Combined Rewards with Vision-Language Model Feedback for Preference-Aligne
d Reinforcement Learning

Hexian Ni, Tao Lu, Yinghao Cai

Reward design remains a central challenge in reinforcement learning (RL). Hand-c
rafted rewards are often difficult to specify and may lead to suboptimal policie
s, while learned rewards from preferences can suffer from inefficiency and unsta
ble training. Inspired by the dual nature of human learning explored in cognitiv
e science, we decompose rewards into two complementary components: Formal Reward
s (FR), explicitly designed based on task knowledge, and Residual Rewards (RR),
learned from observations to capture implicit and nuanced preferences. Based on
this decomposition, we propose CoRe, a hybrid framework that integrates FR and R
R with vision-language models (VLMs) feedback to achieve preference-aligned poli
cies without human involvement. Our contributions are twofold: (1) We propose a
Formal Reward Module (FRM) that leverages VLMs to iteratively design and optimiz
e FR based on task knowledge and preference feedback, enabling the continual imp
rovement of policy during training; (2) We introduce a Residual Reward Module (R
RM) that learns RR from video-level preference by employing VLMs to generate pre
ference labels and capturing nuanced rewards that complement FR, ensuring alignm
ent with human intent. Through the synergy of FRM and RRM, CoRe enables the auto
matic construction of reliable rewards that are efficient and preference-aligned
. Extensive experiments demonstrate that CoRe outperforms existing approaches in
 terms of policy learning effectiveness and efficiency on ten robotic manipulati
on tasks in simulation and five real-worlds.

MFH-NAS:A Hybrid Neural Architecture Search Framework for Multimodal Fusion Obje
ct Detection

Quanwei Gao, Shuqi Zhao, Ruyu Wang, Shuyin Zhang, Cong Liu, Zirui Luo

Multimodal fusion object detection faces a substantial modality gap at the same
backbone stage. This makes predefined stage-aligned fusion insufficient for cros
s-stage interactions. We propose MFH-NAS, a hybrid neural architecture search fr
amework that automatically discovers fusion architectures to better leverage cro
ss-modal complementarity. MFH-NAS searches both local fusion primitives and stag
e-level fusion connectivity. It targets fusion operator design and fusion stage
selection. It couples differentiable search with evolutionary search. Differenti
able search learns architecture parameters for local fusion primitives. Evolutio
nary search explores global fusion topologies, including stage selection and cro
ss-stage connection patterns. The joint search balances exploitation and explora
tion and mitigates premature convergence. It yields fusion structures that stren
gthen cross-stage interactions.We evaluate MFH-NAS on three public benchmarks, L
LVIP, RGBT-Tiny, and M3FD. MFH-NAS consistently outperforms handcrafted fusion-s
tage designs and prior stage-searching NAS baselines, improving mAP@0.5 from 85.
3% to 88.2% over strong fixed-stage fusion methods and delivering gains across
all benchmarks.The code is available at https://github.com/someboy0/MFH-NAS.

Error Propagation in Dynamic Programming: From Stochastic Control to American Op
tion Pricing

Andrea Della Vecchia, Damir Filipovic
This paper investigates theoretical and methodological foundations for stochasti c optimal control (SOC) in discrete time. We start formulating the control probl em in a general dynamic programming framework, introducing the mathematical stru cture needed for a detailed convergence analysis. The associate value function i s estimated through a sequence of approximations combining nonparametric regress ion methods and Monte Carlo subsampling. The regression step is performed within reproducing kernel Hilbert spaces (RKHSs), exploiting the classical KRR algorit hm, while Monte Carlo sampling methods are introduced to estimate the continuati on value. To assess the accuracy of our value function estimator, we propose a n atural error decomposition and rigorously control the resulting error terms at e ach time step. We then analyze how this error propagates backward in time-from m aturity to the initial stage-a relatively underexplored aspect of the SOC litera ture. Finally, we illustrate how our analysis naturally applies to a key financi al application: the pricing of American options.

E-mem: Multi-Agent Based Episodic Context Reconstruction for LLM Agent Memory
Kaixiang Wang, Yidan Lin, Zihan Wang, Bunyod Suvonov, Zhaojiacheng Zhou, Yuxiang Zheng, Jiaxi Cao, Zhiheng Dong, Chentao Wu, Jiong Lou, Jie LI
The evolution of Large Language Model (LLM) agents towards System~2 reasoning, c haracterized by deliberative, high-precision problem-solving, necessitates maint aining rigorous logical integrity over extended horizons. However, prevalent mem ory preprocessing paradigms incur destructive de-contextualization. By compressi ng fluid sequential dependencies into pre-defined structures (e.g., embeddings o r graphs), these methods sever the narrative integrity essential for deep reason ing. To address this, we propose E-mem, a framework shifting from Memory Preproc essing to Episodic Context Reconstruction inspired by biological engrams. E-mem employs a heterogeneous hierarchical architecture where multiple assistant agent s maintain uncompressed memory contexts, while a central master agent orchestrat es global planning. Unlike passive retrieval, our mechanism empowers assistants to locally reason within activated segments, extracting context-aware evidence b efore aggregation. Evaluations on the LoCoMo benchmark demonstrate that E-mem ac hieves over 54\% F1—surpassing the state-of-the-art GAM by 7.75\%—while reducing token cost by over 70\%. Our work is available on \url{https://anonymous.4open. science/r/E-mem-F6C3/}.

iTryOn: Mastering Interactive Video Virtual Try-On with Spatial-Semantic Guidanc e
Jun Zheng, Zhengze Xu, Mengting Chen, Jing Wang, Jinsong Lan, Xiaoyong Zhu, Kaif u Zhang, Bo Zheng, Xiaodan Liang
Video Virtual Try-On (VVT) aims to seamlessly replace a garment on a person in a video with a new one. While existing methods have made significant strides in m aintaining temporal consistency, they are predominantly confined to non-interact ive scenarios where models merely showcase garments. This limitation overlooks a crucial aspect of real-world apparel presentation: active human-garment interac tion. To bridge this gap, we introduce and formalize a new challenging task: Int eractive Video Virtual Try-On (Interactive VVT), where subjects in the video act ively engage with their clothing (e.g., pulling a hem or unzipping a jacket). Th is task introduces unique challenges beyond simple texture preservation, includi ng: (1) resolving the semantic ambiguity of interactions from standard pose info rmation, and (2) learning complex garment deformations from video where interact ive moments are sparse and brief.
To address these challenges, we propose **iTryOn**, a novel framework built upon a large-scale video diffusion Transformer. iTryOn pioneers a multi-level intera ction injection mechanism to guide the generation of complex dynamics. At the sp atial level, we introduce a garment-agnostic 3D hand prior to provide fine-grain ed guidance for precise hand-garment contact, effectively resolving spatial ambi guity. At the semantic level, iTryOn leverages global captions for overall conte xt and time-stamped action captions for localized interactions, synchronized via our novel Action-aware Rotational Position Embedding (A-RoPE). Furthermore, we

design an action-aware constraint loss to stabilize training and focus the learning process on these critical interactive frames. To facilitate research and evaluation, we construct VVT-Interact, the first large-scale dataset for this task, and propose a novel interaction-aware evaluation metric to quantify the semantic fidelity of interactions. Extensive experiments demonstrate that iTryOn not only achieves state-of-the-art performance on traditional VVT benchmarks but also establishes a commanding lead in the new interactive setting, marking a significant step towards more dynamic and controllable virtual try-on experiences.

Quantifying the Salience of Geo-Cultural Values for Pluralistic Safety Alignment
Arkadiy Saakyan, Charvi Rastogi, Lora Aroyo
Safe global deployment of AI models requires alignment with human values that vary across cultures. Yet rater pools in safety evaluation datasets remain largely geographically homogeneous, failing to capture geo-cultural differences. Further, it remains unclear whether such differences persist after controlling for demographics such as age, gender, and ethnicity. Through a meta-analysis of safety datasets, we find that most do not report geo-cultural information, and those that do lack a unified methodology to jointly analyze geo-cultural and demographic correlates. Using the Inglehart-Welzel dimensions of cross-cultural variation, we demonstrate via multilevel modeling that cultural zone membership explains variance in safety ratings beyond standard demographics ($p<0.05$ across 6 datasets). Moreover, our analysis indicates that roughly 10\% of items in the datasets we examined are culturally sensitive: likely to be misclassified as safe without adequate cultural representation. We evaluate LLMs as both rater surrogates and triage tools, finding that current LLMs do not reliably stand in for raters, though they can help prioritize culturally sensitive items for human annotation. Our findings motivate more culturally pluralistic safety evaluation and offer practical takeaways to support it.

Learning Unmasking Policies for Diffusion Language Models
Metod Jazbec, Theo X. Olausson, Louis Béthune, Pierre Ablin, Michael Kirchhof, Joao Monteiro, Victor Guilherme Turrisi da Costa, Jason Ramapuram, marco cuturi
Diffusion (Large) Language Models (dLLMs) now match the downstream performance of their autoregressive counterparts on many tasks, while holding the promise of being more efficient during inference. One critical design aspect of dLLMs is the \textit{sampling procedure} that selects which tokens to unmask at each diffusion step. Indeed, recent work has found that heuristic strategies such as confidence thresholding improve both sample quality and token throughput compared to random unmasking. However, such heuristics have downsides: they require manual tuning, and we observe that their performance degrades with larger block sizes. In this work, we instead propose to train sampling procedures using reinforcement learning. Specifically, we formalize masked diffusion sampling as a Markov decision process in which the dLLM serves as the environment, and propose a lightweight policy based on a single-layer transformer that maps dLLM token confidences to unmasking decisions. Our experiments show that these trained policies match the performance of state-of-the-art heuristics when combined with semi-autoregressive (block) generation, while outperforming them in the full-diffusion setting. Our code is available at https://github.com/apple/ml-rl-dllm.
****
DenseMLLM: Standard Multimodal LLMs for Dense Prediction
Yi Li, Hongze Shen, Lexiang Tang, Xin Li, Xinpeng Ding, Yinsong Liu, Deqiang Jiang, Xing Sun, Xiaomeng Li
Multimodal Large Language Models (MLLMs) have demonstrated exceptional capabilities in high-level visual understanding. However, extending these models to fine-grained dense prediction tasks, such as semantic segmentation and depth estimation, typically necessitates the incorporation of complex, task-specific decoders and other customizations. This architectural fragmentation increases model complexity and deviates from the generalist design of MLLMs, ultimately limiting their practicality. In this work, we challenge this paradigm by accommodating standa

rd MLLMs to perform dense predictions without requiring additional task-specific decoders. The proposed model is called DenseMLLM, grounded in the standard architecture with a novel vision token supervision strategy for multiple labels and tasks. Despite its minimalist design, our model achieves highly competitive performance across a wide range of dense prediction and vision-language benchmarks, demonstrating that a standard, general-purpose MLLM can effectively support dense perception without architectural specialization. This project is available at github.com/Eli-YiLi/DenseMLLM.

Barriers to Counterfactual Credit Attribution for Autoregressive Models

Aloni Cohen, Chenhao Zhang

Generative AI disrupts the practice of giving credit to work that came before. Ideally, a generative model would give credit to any work on which its output depends in a significant way.

Counterfactual credit attribution (CCA) is a technical condition formalizing this goal---a relaxation of differential privacy---recently introduced by Livni, Moran, Nissim, and Pabbaraju (2024) who studied it in the PAC learning setting. We initiate the study of CCA generative models. Specifically, we consider autoregressive models giving credit to a deployment-time dataset (e.g., a RAG database). We uncover barriers to two natural approaches to CCA autoregressive models. First, we show that imposing CCA on the underlying next-token predictor does not guarantee that the model is CCA: CCA does not compose autoregressively (unlike DP). Second, we consider a different approach to building CCA models which we call *retrofitting*. Retrofitting takes a model that does not attribute credit, and adds credit onto it. Given black-box access to the starting model, retrofitting requires query complexity exponential in the length of the model's outputs.

Learning to Rank from Incomplete Rankings

Cristiano Migali, Gianmarco Genalti, Alberto Maria Metelli, Marco Mussi

In domains such as recommender systems and information retrieval, learning from human-generated feedback is especially challenging because the information provided is often sparse and incomplete. In this work, we address the problem of learning the top-k items from incomplete rankings. Most existing models for incomplete rankings rely on rigid assumptions regarding both the ranking model that generates the latent ranking and the censoring mechanism that determines which comparisons remain unobserved. On the one hand, the ranking model is often assumed to follow a Plackett-Luce (PL) or Mallows distribution. On the other hand, the censoring mechanism is typically assumed to be Missing Completely At Random (MCAR) or to exhibit well-behaved dependencies on the latent ranking, such as winner feedback or top-h feedback. We introduce a new, general framework for learning from incomplete rankings that unifies and strictly generalizes the established frameworks in the literature. We consider the broad class of ranking models that satisfy the complete consensus property, which comprehends all widely adopted models, including PL and Mallows. Furthermore, we present a new preference-based feedback model, named positional censoring, which generalizes winner and top-h feedback. We show that it is possible to learn in this general setting by presenting the PIRATE algorithm and providing a near-optimal instance-dependent bound to the sample complexity. Finally, we show that, under the PL ranking, PIRATE matches the sample complexity of state-of-the-art algorithms in the relevant scenarios of winner and top-h feedback.

Revisiting Distribution Correction Estimation for Offline Imitation Learning with Suboptimal Dataset

Quang Anh Pham, Tien Anh Mai, Akshat Kumar

Imitation Learning (IL) learns high-quality policies from expert demonstrations but degrades in low-expert-data regimes. To address this, recent work studies ``*offline IL with supplementary data*", augmenting expert data with trajectories from suboptimal policies. A prominent framework is Distribution Correction Estimation (DICE), which estimates density ratios via the dual of a divergence minimization problem between learned and expert visitation distributions. However, exi

sting DICE-based methods either rely on a strict coverage assumption or introduc e additional dataset regularization, limiting performance. We propose **ReDICE** , a new DICE-based method that addresses these issues through an objective-level reformulation. Our approach constructs a mixture-distribution objective that pr eserves the original expert-imitation objective while removing the coverage assu mption, and its dual reduces to a stable Gumbel regression objective for efficie nt optimization. We further introduce a novel policy extraction mechanism that i mproves performance. Experiments on standard and real-world offline IL benchmark s show that ReDICE consistently outperforms prior methods and achieves state-of- the-art results.

Batch Normalization for Neural Networks on Complex Domains

Xuan Son Nguyen, Nistor Grozavu

Riemannian neural networks have proven effective in solving a variety of machine learning tasks. The key to their success lies in the development of principled Riemannian analogs of fundamental building blocks in deep neural networks (DNNs) . Among those, Riemannian batch normalization (BN) layers have shown to enhance training stability and improve accuracy. In this paper, we propose BN layers for neural networks on complex domains. The proposed layers have close connections with existing Riemannian BN layers. We derive essential components for practical implementations of BN layers on some complex domains which are less studied in previous works, e.g., the Siegel disk domain. We conduct experiments on radar cl utter classification, node classification, and action recognition demonstrating the efficacy of our method.

Speculative Safety Honeypot: Toward Proactive Defense Against Multi-turn Agent A ttacks

Zezhong WANG, Xueyang Tang, RUI LIAN, Yang Lou, Heqing Huang

As Large Language Model (LLM) agents are increasingly deployed in complex enviro nments, multi-turn interaction attacks have become a significant security challe nge. Existing detection methods typically rely on historical context. However, t his retrospective logic struggles to identify deep malicious intents that are sp lit across turns to hide future risks.

Inspired by speculative decoding, we propose the Speculative Safety Honeypot (SS H) framework. SSH uses a multi-agent simulation system composed of small LLMs to build an action-level speculate-and-verify workflow. In the speculation stage, SSH predicts future behaviors of the target agent and asynchronously builds a tr ajectory tree to expose potential risks in advance. In the verification stage, t he system uses the target agent's real actions to calibrate and prune the trajec tory tree, effectively reducing false positives.

As a plug-and-playable component, SSH provides existing detectors with rich deci sion redundancy beyond the current interaction slice. By judging risk based on t he evolution of the entire trajectory tree rather than a single point in time, t he system reduces the reliance on the absolute precision of individual detection components. This improves the defense resilience and the warning lead-time of a gent systems against complex temporal attacks.

LoRe: Adaptive Interaction-Evaluation Routing with Per-step Interaction Budgets for Iterative Graph Solvers

Jintao Li, Yong-Yi Wang, Zheng-an Wang, Heng Fan

Diffusion-based neural solvers for combinatorial optimization repeatedly re-eval uate dense edge/factor interactions, making inference expensive in wall-clock ti me and often memory-bound at scale. Inspired by the computational methodologies of many-body physics, we introduce LoRe, a training-free, inference-time drop-in wrapper that enforces per-step interaction-evaluation budgeting: at each iterat ion, it evaluates only a fixed fraction of interactions by dynamically routing c omputation to high-conflict or high-uncertainty interactions, instead of using a fixed sparsification (e.g., static kNN graphs or static masks). Under fully inc lusive end-to-end wall-clock accounting, LoRe substantially improves scalability on the Maximum Independent Set (MIS) problem, extending feasible inference more

than $3\times$ beyond the baseline's out-of-memory limit, delivering a ${\sim}8\times$ speedup and a ${\sim}12\times$ peak-memory reduction, with solution quality preserved in this regime. Demonstrating cross-task generality on the large-scale Traveling Salesperson Problem (TSP) and zero-shot robustness to topology shifts, LoRe achieves a ${\sim}15\times$ speedup at $n=1000$ with a $44\times$ memory reduction and competitive tour quality.

Graph of States: Solving Abductive Tasks with Large Language Models
Yu Luo, Rongchen Gao, Lu Teng, Xidao Wen, Jiamin Jiang, Qingliang Zhang, Yongqian Sun, Shenglin Zhang, Jiasong Feng, Tong Liu, Wenjie Zhang, Dan Pei
Logical reasoning encompasses deduction, induction, and abduction.
However, while Large Language Models (LLMs) have effectively mastered the former two, abductive reasoning remains significantly underexplored.
Existing frameworks, predominantly designed for static deductive tasks, fail to generalize to abductive reasoning due to unstructured state representation and lack of explicit state control.
Consequently, they are inevitably prone to Evidence Fabrication, Context Drift, Failed Backtracking, and Early Stopping.
To bridge this gap, we introduce Graph of States (GoS), a general-purpose neuro-symbolic framework tailored for abductive tasks.
GoS grounds multi-agent collaboration in a structured belief states, utilizing a causal graph to explicitly encode logical dependencies and a state machine to govern the valid transitions of the reasoning process.
By dynamically aligning the reasoning focus with these symbolic constraints, our approach transforms aimless, unconstrained exploration into a convergent, directed search.
Extensive evaluations on two real-world datasets demonstrate that GoS significantly outperforms all baselines, providing a robust solution for complex abductive tasks.
Code repo and all prompts: https://github.com/gaorch85/Graph-of-States.

Monotonic Variational Gaussian Process for Efficient Data Collection
Donghyun Lee, Young Myoung Ko
Modeling the learning curve is critical for cost-effective data collection in deep learning systems. Most prior approaches assume a specific parametric learning curve, but these can be inappropriate when no reliable parametric form can be assumed for the learning curve. While Gaussian processes offer flexible nonparametric modeling, existing GP approaches that enforce monotonicity typically introduce intractable factors or require derivative observations. To address this, we propose a Monotonic Variational Gaussian Process for Efficient Data Collection (MOVE), which (i) introduces a novel monotonic variational GP formulation with virtual-derivative factors to enable tractable posterior inference, and (ii) develops an expected shortfall based objective for target-driven data collection. Furthermore, our theoretical analysis shows that expected shortfall provides non-vanishing gradient signals that enable reliable gradient-based optimization. Extensive experiments on classification, segmentation, and detection benchmarks demonstrate consistent improvements over the prior method.

Differentially Private Continual Release with Relative Error
Bo Li, Wei Wang, Peng Ye
This work investigates several fundamental tasks, including MaxSum, MinSum, $\mathsf{MaxSelect}$, and $\mathsf{MinSelect}$, in the continual release model under differential privacy. Previous research has demonstrated that any algorithm for these tasks must admit a large purely additive error. We show that the error can be substantially reduced if a relative error term is allowed, provided that the input stream is generated non-adaptively. However, when input data records can be selected adaptively, we prove that a large error is inevitable for the task of selecting an attribute with a small cumulative sum, whereas small error bounds remain achievable for other tasks. This reveals a significant separation between non-adaptive and adaptive streams. We also complement o

ur algorithms with nearly matching lower bounds.
****
Neutral-Reference Prompting for Vision–Language Models
Senmao Tian, Xiang Wei, Shunli Zhang
Efficient transfer learning of vision–language models (VLMs) commonly suffers fr om a Base–New Trade-off (BNT): improving performance on unseen (new) classes oft en degrades accuracy on known (base) classes. Addressing how to boost recognit ion of unseen classes without sacrificing known-class performance remains a cent ral challenge. Existing work often simplistically attributes the BNT to overfitt ing on known classes.
We observe an interesting phenomenon: VLMs frequently exhibit asymmetric confusi on on certain downstream data, i.e., samples of class A are systematically mispr edicted as class B, while the reverse confusion (B $\rightarrow$ A) rarely occurs. For know n classes, this kind of bias can be mitigated by tuning using a cross-entropy lo ss, but for unseen classes, such pretraining-induced bias persists and harms gen eralization.
Motivated by this, we propose NeRP, a plug-and-play prompting correction strateg y that improves discrimination on unseen classes without modifying model paramet ers. NeRP leverages neutral text prompts and reference images to measure class-w ise prior preferences along the pre-trained inter-class geometry, and combines t hem with the sample likelihood to obtain the model's surrogate score. If, for a given sample, the prior strongly favors the current prediction while the observe d evidence is clearly insufficient, we perform a local flip between easily confu sable class pairs, thereby correcting prior-dominated mispredictions.
Extensive experiments across multiple backbones and 15 few-shot and cross-domain benchmarks show that NeRP substantially improves accuracy on unseen classes whi le preserving known-class prediction performance.

Olivia: Harmonizing Time Series Foundation Models with Power Spectral Density
Jingru Fei, Kun Yi, Alex Xing Wang, Qingsong Wen, Xiangxiang Zhu, Wei Fan
Time series foundation models rely on large-scale pretraining over diverse datas ets across domains, yet their heterogeneity in temporal patterns could hinder th e effectiveness of training and learning transferable time series representation s. Inspired a fundamental concept, normalized power spectral density (PSD) in si gnal processing, we assume harmonizing datasets via PSDs in the spectral domain could reduce mismatches and enhance pretraining. We then go beyond the direct in tractable minimization optimization and innovatively reformulate it as a princip led harmonization approach. Specifically, we propose Harmonizer, a module that r eshapes spectral structures and implicitly harmonizing PSDs across datasets, whi ch theoretically corresponds to a shared reparameterization of second-order temp oral correlations. Our theoretical analysis further reveals token interactions w ith Harmonizer can be efficiently mediated by a compact set of resonators, motiv ating a HarmonicAttention design that performs self-attention in a low-dimension al interaction space. Then, we propose Olivia, a novel time series foundation mo del built upon these harmonization mechanisms. Extensive experiments on several large-scale benchmarks (TSLib, GIFT-Eval, and GluonTS), demonstrate Olivia consi stently achieves state-of-the-art performance under zero-shot, few-shot, and ful l-shot forecasting scenarios. Our code is at \url{https://github.com/TSTS13/Oliv ia}.

Finding DoRI: Discovery of Retained Images in Diffusion Models
Antoni Kowalczuk, Dominik Hintersdorf, Lukas Struppek, Kristian Kersting, Adam D ziedzic, Franziska Boenisch
Text-to-image diffusion models (DMs) have achieved remarkable success in image g eneration. However, concerns about data privacy and intellectual property remain due to their potential to inadvertently memorize and replicate training data. R ecent mitigation efforts have focused on identifying and pruning weights respons ible for triggering verbatim training data replication, based on the assumption that memorization can be localized. We challenge this assumption and demonstrate that, even after such pruning, small perturbations to the text embeddings of pr eviously mitigated prompts can re-trigger data replication, revealing the fragil ity of such methods.
Our further analysis then provides multiple indications that memorization is ind eed *not* inherently local: (1) replication triggers for memorized images are di stributed throughout text embedding space; (2) embeddings yielding the same repl icated image produce divergent model activations; and (3) different pruning meth ods identify inconsistent sets of memorization-related weights for the same imag e. Finally, we show that bypassing the locality assumption enables more robust m itigation through adversarial fine-tuning. These findings provide new insights i nto the fundamental nature of memorization in text-to-image DMs and inform the f uture development of more reliable mitigation methods against DM memorization.

HIVE-3D: Hierarchical Voxel Enhancement for High-Quality 3D Scene Generation
Bin Zang, Wenting Zheng, Xiaoliang Luo, Zhiyuan Fang, Shi Li, Lvchun Wang, Wei Y u, Yi Zhao, Tian Xie, Yuchi Huo, Rengan Xie
Recently, a line of works can generate impressive 3D objects from a single image , but they are limited by restricted representation resolution, making them unsu itable for 3D scene generation. In this work, we introduce HIVE-3D, a novel meth od for high-quality 3D scene generation based on hierarchical voxel enhancement framework. Specifically, given a single scene image as input, we first produce a coarse initial scene, then introduce image segmentation and attention-based ret rieval to align 2D image components with 3D scene components. Subsequently, we o rganize these scene relations into a hierarchical component tree, where nodes cl oser to the leaves denote finer-grained components. Finally, we propose a voxel super-resolution model that generates refined voxels for the target instance whi le maintaining strong consistency with the coarse voxels. Equipped with this mod el, we perform coarse-to-fine hierarchical super-resolution on images and voxels for each component, producing a high-resolution and high-quality 3D scene. Exte nsive experiments demonstrate that our method significantly outperforms previous approaches, achieving state-of-the-art performance.

CausalRAG2: Hierarchical Causal Knowledge Graph Design for RAG
Nengbo Wang, Tuo Liang, Vikash Singh, Chaoda Song, Van Yang, Yu Yin, Jing Ma, JA GDIP SINGH, Vipin Chaudhary
Retrieval augmented generation (RAG) has enhanced large language models by enabl ing access to external knowledge, with graph-based RAG emerging as a powerful pa radigm for structured retrieval and reasoning. However, existing graph-based met hods often over-rely on entity-centric node matching and lack explicit causal mo deling, leading to unfaithful or spurious answers. Prior attempts to incorporate causality are typically limited to local or single-document contexts and also s uffer from information isolation that arises from modular graph structures, whic h hinders scalability and cross-module causal reasoning. To address these challe nges, we propose CausalRAG2, a framework that rethinks knowledge organization fo r graph-based RAG through causal gating across hierarchical modules. CausalRAG2 explicitly models causal relationships to suppress spurious correlations while e nabling scalable reasoning over large-scale knowledge graphs. We also introduce HolisQA, a benchmark for holistic comprehension beyond entity-centric matching. Extensive experiments demonstrate that CausalRAG2 consistently outperforms compe titive graph-based RAG baselines across multiple datasets and evaluation metrics

. Our work establishes a principled foundation for structured, scalable, and cau
sally grounded RAG systems.

LoCoT2V-Bench: Benchmarking Long-Form and Complex Text-to-Video Generation
Xiangqing Zheng, Chengyue Wu, Kehai Chen, Min Zhang
Recent advances in text-to-video generation have achieved impressive performance
 on short clips, yet evaluating long-form generation under complex textual input
s remains a significant challenge. In response to this challenge, we present LoC
oT2V-Bench, a benchmark for long video generation (LVG) featuring multi-scene pr
ompts with hierarchical metadata (e.g., character settings and camera behaviors)
, constructed from collected real-world videos. We further propose LoCoT2V-Eval,
 a multi-dimensional framework covering perceptual quality, text-video alignment
, temporal quality, dynamic quality, and Human Expectation Realization Degree (H
ERD), with an emphasis on aspects such as fine-grained text-video alignment and
temporal character consistency. Experiments on 17 representative LVG models reve
al pronounced capability disparities across evaluation dimensions, with strong p
erceptual quality and background consistency but markedly weaker fine-grained te
xt-video alignment and character consistency. These findings suggest that improv
ing prompt faithfulness and identity preservation remains a key challenge for lo
ng-form video generation. Our code and data are released at [https://github.com/
XqZeppelinhead0702/LoCoT2V-Bench](https://github.com/XqZeppelinhead0702/LoCoT2V-
Bench).

FRISM: Fine-Grained Reasoning Injection via Subspace-Level Model Merging for Vis
ion–Language Models
Chenyu Huang, Peng Ye, Xudong Tan, Jinhan Mu, Shenghe Zheng, Li Shen, Tao Chen
Efficiently enhancing the reasoning capabilities of Vision-Language Models (VLMs
) by merging them with Large Reasoning Models (LRMs) has emerged as a promising
direction. However, existing methods typically operate at a coarse-grained layer
 level, which often leads to a trade-off between injecting reasoning capabilitie
s and preserving visual capabilities.
To address this limitation, we propose FRISM (Fine-grained Reasoning Injection v
ia Subspace-level model Merging), a fine-grained reasoning injection framework b
ased on subspace-level model merging.
Observing that different SVD subspaces contribute differently to reasoning and p
erception,
FRISM decomposes LRM task vectors via Singular Value Decomposition (SVD) and ada
ptively tunes the scaling coefficients of each subspace through learning to real
ize fine-grained reasoning injection.
Furthermore, we introduce a label-free self-distillation learning strategy with
dual-objective optimization using common vision-language perception datasets.
Extensive experiments demonstrate that FRISM effectively improves reasoning capa
bilities while largely preserving the model's visual capabilities by
consistently achieving strong performance across diverse visual-language reasoni
ng benchmarks.

Quantifying and Optimizing Simplicity via Polynomial Representations
Tianren Zhang, Xiangxin Li, Minghao Xiao, Guanyu Chen, Feng Chen
Deep networks often exhibit a preference for "simple" solutions, and such a simp
licity bias is widely believed to play a key role in generalization. Yet a broad
ly applicable, quantitative measure of simplicity remains elusive. We introduce
polynomial representations as a distribution-aware, low-dimensional surrogate
for neural functions: we approximate a network’s predictive behavior along data-
dependent interpolation paths using orthogonal polynomial bases, yielding a comp
act functional representation. We show that the _effective degree_ of this repre
sentation serves as a practical simplicity metric that is predictive of generali
zation across tasks and architectures, and consistently outperforms existing gen
eralization proxies such as sharpness. Finally, polynomial representations natur
ally yield a _differentiable_ simplicity regularizer, which consistently improve
s generalization in image and text classification, fine-tuning contrastive visio

n–language models, and reinforcement learning.
****
MarketSim: Simulating Stock Markets with Large-Scale Generative Agents
Jinghua Piao, zhentao liu, Cheng Huang, Jiarui Huang, Songwei Li, Ranran Wang, Y ong Li
Stock markets are one of the most complex systems in the modern world, where pri ces emerge from billions of decentralized interactions among heterogeneous parti cipants in an ever-evolving information landscape. While high-fidelity simulatio n is important for understanding market dynamics, existing approaches face a per sistent trade-off between structural and behavioral fidelity. To this end, we pr opose MarketSim, a large-scale stock market simulation framework with generative agents. MarketSim introduces a hierarchical multi-agent architecture that decou ples strategic reasoning from high-frequency execution, enabling LLM agents to o perate in a nanosecond-resolution, NASDAQ-like continuous double auction market. Building on this, we simulate over 15,000 heterogeneous market participants who se interactions shape and are shaped by an evolving market environment grounded in more than 12k real-world news articles, policy documents, and earnings report s. To evaluate our proposed MarketSim, we develop a comprehensive benchmark that includes stocks from 8 GICS sectors and 3 representative real-world scenarios, along with 5 stylized facts for market complexity and 5 price-related statistica l metrics. Extensive experiments demonstrate that MarketSim not only captures ke y complexity properties of real-world markets, but also outperforms state-of-the -art baselines in tracking high-frequency price dynamics with an average MAPE of 3.48%, providing a scalable testbed for market analysis.
****
PRISM: Parallel Residual Iterative Sequence Model
Jie Jiang, Ke Cheng, Xin Xu, Mengyang Pang, Tianhao Lu, Jiaheng Li, Yue Liu, Yua n Wang, Jun Zhang, Huan Yu, Zhouchen Lin
Generative sequence modeling faces a fundamental tension between the expressivit y of Transformers and the efficiency of linear sequence models. Existing efficie nt architectures are theoretically bounded by shallow, single-step linear update s, while powerful iterative methods like Test-Time Training (TTT) break hardware parallelism due to two dimensions of serial dependency: token-level state relia nce and step-level iteration loops. We propose PRISM (Parallel Residual Iterativ e Sequence Model) to resolve this tension. PRISM explicitly reconstructs the exp ressive gate × residual × direction iteration pattern of TTT in a parallelizable form. We employ a Write-Forget Decoupling strategy that isolates non-linearity within the injection operator. To bypass the serial dependency of explicit solve rs, PRISM utilizes a two-stage proxy architecture: a short-convolution anchors t he initial residual using local history energy, while a learned predictor estima tes the refinement updates directly from the input. This design distills structu ral patterns associated with iterative correction into a parallelizable feedforw ard operator. Theoretically, we prove that this formulation achieves Rank-L ac cumulation, structurally expanding the update manifold beyond the single-step Ra nk-1 bottleneck. Empirically, it achieves comparable performance to explicit o ptimization methods while achieving 174x higher throughput. Codes are available in \url{https://github.com/gpr-prism/prism/}.
****
Task-Aware Exploration via a Predictive Bisimulation Metric
Dayang Liang, Ruihan LIU, Lipeng Wan, Yunlong Liu, Bo An
Accelerating exploration in visual reinforcement learning under sparse rewards r emains challenging due to the substantial task-irrelevant variations. Despite ad vances in intrinsic exploration, many methods either assume access to low-dimens ional states or lack task-aware exploration strategies, thereby rendering them f ragile in visual domains. To bridge this gap, we present TEB, a Task-aware Explo ration approach that tightly couples task-relevant representations with explorat ion through a predictive Bisimulation metric. Specifically, TEB leverages the me tric not only to learn behaviorally grounded task representations but also to me asure global intrinsic novelty over the learned latent space. To realize this, w e first theoretically mitigate the representation collapse of degenerate bisimul

ation metrics under sparse rewards by internally introducing a simple but effect ive predicted reward differential term. Building on this robust metric, we furth er introduce potential-based global exploration bonuses over anchor states, whic h measure the relative novelty between observations over the latent space. Exten sive experiments on MetaWorld and Maze2D show that TEB achieves superior explora tion ability and outperforms recent baselines.

Intra-Modal Neighbors Never Lie: Rectifying Inter-Modal Noisy Correspondence via Graph-Based Intra-Modal Reasoning
Yang Liu, Wentao Feng, Shu-Dong Huang, Yalan Ye, Jiancheng Lv
Large-scale web-harvested datasets have fueled the progress of cross-modal retri eval but inevitably suffer from noisy correspondence, which severely degrades mo del generalization. Existing methods primarily address this by filtering out noi se or seeking a substitute label, yet they predominantly remain bound by a “Disc rete Selection” paradigm. We argue that relying on a single discrete proxy induc es SinglePoint Fragility and Discretization Error. To overcome these limitations , we propose a novel framework, Intra-modal Neighbor-aware Noise Rectification (IN2R), which shifts the paradigm from searching for a substitute to synthesizing a reliable supervision target. Leveraging the intrinsic geometric stability of intra-modal data, IN2R employs a Graph Refiner to perform relational reasoning o ver neighbors retrieved from a dynamic Cross-Model Memory. Instead of propagatin g discrete labels, our method synthesizes a continuous, soft prototype that refl ects the consensus of the local semantic neighborhood, effectively rectifying in ter-modal misalignment. Extensive experiments on Flickr30K, MS-COCO, and CC152K demonstrate that IN2R significantly outperforms state-of-the-art methods.

Bridging Tokens and Geometry: Token-wise 3D Supervision for CAD Generation
Yijia Guan, Jianhua Sun
Computer-Aided Design (CAD) generation is typically formulated as a sequence mod eling task over parametric tokens. Recent studies introduce visual information t hrough additional visual inputs or rendering of the final generated programs. Ho wever, these methods provide no intermediate visual feedback, hindering the asso ciation of individual tokens with their geometric effects. In this work, we prop ose an Argument-induced 3D Point Loss (A3PL) that maps argument tokens to corres ponding 3D points, enabling dense token-wise geometric supervision. To reduce le arning complexity and invalid sequences, we further introduce a Grammar-constrai ned Operator (GCO) that leverages the structured nature of CAD programs to regul ate sequence generation. We evaluate our approach on five CAD generation tasks w ith diverse input modalities, including text, Scalable Vector Graphics (SVG) ske tches, point clouds, and CAD sequences. Our approach improves generation accurac y and program validity across different input modalities. Code is available at h ttps://github.com/JumpJumpTigger-GYJ/A3PL.

ZeroBench: An Impossible Visual Benchmark for Contemporary Large Multimodal Models
Jonathan Roberts, Mohammad Reza Taesiri, Ansh Sharma, Akash Gupta, Samuel Roberts, Ioana Croitoru, Simion-Vlad Bogolin, Jialu Tang, Florian Langer, Vyas Raina, Vatsal Raina, Hanyi Xiong, Vishaal Udandarao, Jingyi Lu, Chen Shiyang, Sam Purkis, Tianshuo Yan, Wenye Lin, Gyungin Shin, Qiaochu Yang, Anh Totti Nguyen, David Atkinson, Alexandru Coca, Mikah Dang, Sebastian Dziadzio, Jakob D. Kunz, Kaiqu Liang, Alexander Lo, Brian Pulfer, Steven Walton, Charig Yang, Kai Han, Samuel Albanie
Large Multimodal Models (LMMs) exhibit shortfalls when interpreting images and, by some measures, have poorer spatial cognition than young children or animals. Despite this, they attain high scores on many popular visual benchmarks, with headroom rapidly eroded by model progress. This creates a need for difficult benchmarks that remain relevant for longer. We introduce ZeroBench—a lightweight visual reasoning benchmark curated using adversarial filtering to be “impossible” for frontier LMMs at its original release, with initial SotA scores of 0% pass@1 and pass∧5. We track progress on ZeroBench over the subsequent year, observing SotA reaching 6% pass∧5 and 19% pass@5, indicating the potential longevity of the benchmark. We evaluate 46 LMMs on ZeroBench, compare performance to a human baseline, analyse strengths and weaknesses, chart a year of progress in visual capabilities, and publicly release ZeroBench at https://zerobench.github.io/.
****
Theory of Continual Learning Against Data Poisoning Attacks
Yiting Hu, Lingjie Duan
Continual learning (CL), where a model is trained on a sequence of data tasks, is increasingly being adopted across key fields such as large language models and image recognition, yet it remains highly vulnerable to data poisoning that triggers learning divergence or severe excess risk. Despite these threats, a principled theoretical foundation in CL for understanding attack and defense remains lacking. In this paper, we develop a theoretical framework to analyze strategic attacks and defenses in regularization-based CL, a cornerstone of recent CL theory. By framing the adversary-defender interaction as an online zero-sum game, we first establish a fundamental performance limit: no defense succeeds when an adversary poisons a linear proportion of tasks by injecting unbounded noise or pattern shifts in regularization-based CL. We then analyze two possibly defensible scenarios: infrequent attacks and bounded noise per attack. For the former regime, we propose a task-to-task verification mechanism to detect data poisoning and reduce cumulative bias for learning convergence. For the latter regime, we derive a robust defense that minimizes the model’s sensitivity to poisoned features, provably accelerating the convergence rate. Extensive experiments on realistic tasks further validate our theoretical results.
****
Omni-Diffusion: Unified Multimodal Understanding and Generation with Masked Discrete Diffusion
lijiang Li, Zuwei Long, Yunhang Shen, Heting Gao, Haoyu Cao, Xing Sun, Caifeng Shan, Ran He, Chaoyou Fu
While recent multimodal large language models (MLLMs) have made impressive strides, they mostly employ a conventional autoregressive architecture as their backbone, leaving significant room for exploring effective and efficient alternatives in architectural design. Meanwhile, recent studies have successfully applied discrete diffusion models to natural language processing, revealing their considerable potential as a promising new approach in this domain. Drawing inspiration from these pioneering studies, we introduce Omni-Diffusion, the first any-to-any multimodal language model built entirely on mask-based discrete diffusion models, which unifies understanding and generation across text, speech, and images. Omni-Diffusion employs a unified mask-based discrete diffusion model to directly capture the joint distribution over discrete multimodal tokens. This approach supports not only bimodal tasks but also more complex scenarios involving multiple modalities. On a diverse set of benchmarks, our method outperforms or performs o

n par with existing multimodal systems that process two or more modalities, high lighting the significant promise of diffusion models in powering the next genera tion of multimodal foundation models. Our codes are released at [GitHub](https:/ /omni-diffusion.github.io).
****
Parameters as Experts: Adapting Vision Models with Dynamic Parameter Routing
Meng Lou, Stanley Yu, Yizhou Yu
Adapting pre-trained vision models using parameter-efficient fine-tuning (PEFT) remains challenging, as it aims to achieve performance comparable to full fine-t uning using a minimal number of trainable parameters. When applied to complex de nse prediction tasks, existing methods exhibit limitations, including input-agno stic modeling and redundant cross-layer representations. To this end, we propose ParaX, a new adapter-style method featuring a simple mixture-of-experts (MoE) a rchitecture. Specifically, we introduce shared expert centers, where each expert is a trainable parameter matrix. During a feedforward pass, each ParaX module i n the network dynamically generates weight matrices tailored for the current mod ule via a simple dynamic parameter routing mechanism, which selectively aggregat es parameter matrices in the corresponding expert center. Dynamic weight matrice s in ParaX modules facilitate low-rank adaptation in an input-dependent manner, thus generating more customized and powerful feature representations.
Moreover, since ParaX modules across multiple network layers share the same expe rt center, they improve feature diversity by promoting implicit cross-layer feat ure interaction.
Extensive experimental results demonstrate the superiority of ParaX across diver se visual recognition tasks.
Code is publicly released at: https://github.com/LMMMEng/ParaX.

Feedback Control for Multi-Objective Graph Self-Supervision
Karish Grover, Theodore Vasiloudis, Han Xie, Sixing Lu, Xiang song, Christos Fal outsos
Can multi-task self-supervised learning on graphs be coordinated without the usu al tug-of-war between objectives? Graph self-supervised learning (SSL) offers a growing toolbox of pretext objectives—mutual information, reconstruction, contra stive learning—yet combining them reliably remains a challenge due to objective interference and training instability. Most multi-pretext pipelines use per-upda te mixing, forcing every parameter update to be a compromise, leading to three f ailure modes: Disagreement (conflict-induced negative transfer), Drift (nonstati onary objective utility), and Drought (hidden starvation of underserved objectiv es). We argue that coordination is fundamentally a temporal allocation problem: deciding when each objective receives optimization budget, not merely how to wei gh them. We introduce ControlG, a control-theoretic framework that recasts multi -objective graph SSL as feedback-controlled temporal allocation by estimating pe r-objective difficulty and pairwise antagonism, planning target budgets via a Pa reto-aware log-hypervolume planner, and scheduling with a Proportional–Integral– Derivative (PID) controller. Across 9 datasets, ControlG consistently outperform s state-of-the-art baselines, while producing an auditable schedule that reveals which objectives drove learning.
****
Correcting Visual Blur Induced by Attention Distraction to Reduce Hallucinations : Algorithm and Theory
Quanjiang Li, Zhiming Liu, Wei Luo, Tingjin Luo, Chenping Hou
Multimodal large language models (MLLMs) frequently suffer from object hallucina tions, yet the visual perceptual mechanism underlying this failure remains poorl y understood. In this work, we reveal that hallucinations are strongly associate d with a human-like attention distraction phenomenon, where humans under divided focus experience degraded visual clarity and produce inaccurate descriptions, w hile in models the same mechanism manifests as spatial inconsistency in multi-he ad attention and temporal fading of attention to image tokens during decoding. W e further provide theoretical insights that attention dispersion increases mode l complexity and degrades classification generalization. Motivated by these find

ings, we propose an Attention-Focused Approach for Improved Image Perception (AFIP), which corrects attention distraction via cross-head attention enrichment and reinforces visual grounding through dynamic historical attention enhancement. Extensive experiments on multiple benchmarks and models validate the effectiveness of AFIP without additional training.

Projection-Free Algorithms for Minimax Problems

Khanh-Hung Giang-Tran, Soroosh Shafiee, Nam Ho-Nguyen

This paper addresses constrained smooth saddle-point problems in settings where projection onto the feasible sets is computationally expensive. We bridge the gap between projection-based and projection-free optimization by introducing a unified dual dynamic smoothing framework that enables the design of efficient single-loop algorithms. Within this framework, we establish convergence results for nonconvex-concave and nonconvex-strongly concave settings. Furthermore, we show that this framework is naturally applicable to convex-concave problems, providing a unified analysis across varying payoff structures. We propose and analyze three algorithmic variants based on the application of a linear minimization oracle over the minimization variable, the maximization variable, or both. Notably, our analysis yields anytime convergence guarantees without requiring a pre-specified iteration horizon. These results significantly narrow the performance gap between projection-free and projection-based methods for minimax optimization.

The Labyrinth and the Thread: Rethinking Regularizations in Sequential Knowledge Editing for Large Language Models

Zheng Wang, Kaixuan Zhang, Wanfang Chen, Jingwen Zhang, Xiaonan Lu

Sequential editing of structured knowledge in large language models allows targeted factual updates without retraining, yet existing methods often rely on complex regularization or constraint mechanisms whose necessity remains unclear. In this work, we systematically investigate the mechanisms underlying effective and stable sequential editing. Specifically, we first analyze the empirical success of AlphaEdit and establish, via a rigorous optimization analysis, the formal equivalence between one-time and sequential editing. Building on this insight, we generalize the equivalence to a broader class of editing objectives, demonstrating that stability emerges naturally from properly accounting for accumulated editing constraints, rather than from specialized regularization or null-space operations. We empirically confirm that many commonly used regularization strategies are unnecessary for reliable sequential updates. Furthermore, we extend our framework to handle conflicting edits, ensuring robust and consistent behavior under contradictory updates. Ultimately, our work provides Ariadne's thread through the labyrinth of sequential editing, charting a path toward simpler, more interpretable, and dependable knowledge updates. Our code is available at https://github.com/Wangzzzzzzz/OTE-SE-Alignment.

Coarse-Grained Boltzmann Generators

Weilong Chen, Bojun Zhao, Jan Eckwert, Julija Zavadlav

Sampling equilibrium molecular configurations from the Boltzmann distribution is a longstanding challenge. Boltzmann Generators (BGs) address this by combining exact-likelihood generative models with importance sampling, but practical scalability is limited. Meanwhile, coarse-grained surrogates enable the modeling of larger systems by reducing effective dimensionality, yet often lack a reweighting procedure required to ensure asymptotically correct statistics. In this work, we propose Coarse-Grained Boltzmann Generators (CG-BGs), a framework for reduced-order generative modeling with importance sampling in coarse-grained coordinate space. CG-BGs generate samples using a flow-based model and reweight them using a learned potential of mean force (PMF). We show that the PMF can be learned from rapidly converged trajectories via enhanced sampling force matching. Experiments demonstrate that CG-BGs capture solvent-mediated interactions in highly reduced representations while substantially reducing computational cost relative to atomistic BGs, providing a practical route toward equilibrium sampling of larger molecular systems.

Backward SDE–Based Diffusion for Physics-Constrained Generation
Zihao WANG
Pretrained score-based diffusion models provide strong unconditional priors, yet enforcing measurement or physics consistency in inverse problems is often handled by heuristic guidance, intermittent projections, or task-specific conditional training, with limited guarantees of feasibility at the end of inference. We propose terminal-conditioned inversion for score-based SDE priors. Given a frozen Score-SDE prior and a task-defined terminal feasibility specification, we construct an associated backward stochastic differential equation whose adapted solution defines a principled inverse map from the terminal requirement to a prior state at a chosen noise level. Under standard regularity conditions, we establish existence and uniqueness of the adapted solution and obtain terminal consistency by construction. We further develop a practical neural BSDE solver that composes arbitrary pretrained diffusion priors with domain constraints without modifying the score-defined coefficients, producing an anchored prior state that enables neighborhood sampling for uncertainty characterization. Experiments on toy datasets validate stable terminal-conditioned inversion and distributionally consistent neighborhood sampling. As a real-world case study, we apply the framework to sparse-view CT reconstruction and achieve improved reconstruction quality over representative training-free baselines while satisfying strict measurement feasibility under the prescribed terminal specification.
****
Principled SVD-based Delta Compression via Quantization Error Minimization
Boya Xiong, Shuo Wang, Weifeng Ge, Guanhua Chen, Yun Chen
Supervised Fine-Tuning (SFT) empowers Large Language Models (LLMs) with exceptional performance on specialized tasks, but it yields dense, high-dimensional delta parameters that pose severe storage and distribution challenges. Singular Value Decomposition (SVD)-based compression offers a compact representation for such delta parameters, but existing methods adopt heuristic quantization without clarifying underlying mechanisms, leading to poor generalizability. In this work, we propose PrinMix, a rigorous SVD-based framework that models quantization as an optimization problem, grounding the design in mathematical mechanisms. We first theoretically derive quantization error and identify a key singular-value-dominated scaling mechanism, which mathematically proves the necessity of mix-precision quantization. We then model the quantization scheme as a 0/1 Integer Linear Programming (ILP) problem, which yields optimal bit-budget-constrained solutions without empirical assumptions. Furthermore, PrinMix integrates a Reconstruction Target Correction (RTC) method to compensate for errors from the $\mathbf{V}$-then-$\mathbf{U}$ sequential quantization process. Extensive experiments confirm PrinMix performs well: for 7B LLMs, PrinMix outperforms SOTA Delta-CoMe on challenging benchmarks by 22.3\% on AIME2024 and 6.1\% on GQA.
****
Tucker Attention: A generalization of approximate attention mechanisms
Timon Klein, Jonas Kusch, Sebastian Sager, Stefan Schnake, Steffen Schotthöfer
The pursuit of reducing the memory footprint of the self-attention mechanism in multi-headed self attention (MHA) spawned a rich portfolio of methods, e.g., group-query attention (GQA) and multi-head latent attention (MLA). The methods leverage specialized low-rank factorizations across embedding dimensions or attention heads. From the point of view of classical low-rank approximation, these methods are unconventional and raise questions of which objects they really approximate and how to interpret the low-rank behavior of the resulting representations. To answer these questions, this work proposes a generalized view on the weight objects in the self-attention layer and a factorization strategy, which allows us to construct a parameter efficient scheme, called Tucker Attention.
Tucker Attention requires an order of magnitude fewer parameters for comparable validation metrics, compared to GQA and MLA, as evaluated in LLM and ViT test cases. Additionally, Tucker Attention~encompasses GQA, MLA, MHA as special cases and is fully compatible with flash-attention and rotary position embeddings (RoPE).

This generalization strategy yields insights of the actual ranks achieved by MHA , GQA, and MLA, and further enables simplifications for MLA.

Uni-DocRobust: Universal Plug-and-Play Robustness Enhancement for Multi-modal LL Ms via Feature Restoration
Yuxuan Zhou, Baole Wei, Xingjian Hu, Haowei Chen, Yu Li, Xingyue Lin, Liangcai G ao, Zhi Tang
Real-world degradations, such as noise, blur, and low resolution, significantly impair the performance of Multi-modal Large Language Models (MLLMs) in document understanding tasks. Despite recent advancements, progress in this field remains stifled by two critical bottlenecks: the scarcity of large-scale, aligned train ing data necessary for learning robustness, and the lack of transferable restora tion solutions across diverse MLLM architectures. To bridge the data gap, we fir st present DocRobust-VQA, a large-scale dataset explicitly constructed to suppor t robustness training. Comprising 189K aligned clean/corrupted document image pa irs and 417K QA pairs, it provides the first substantial corpus for fine-tuning MLLMs to handle varying degradation conditions. Leveraging this data, we propose Uni-DocRobust, a universal plug-and-play framework that decouples restoration c apabilities from specific visual encoders. Our method employs a frozen Universal Restoration Core pre-trained in a canonical feature space via multi-teacher dis tillation, which can be seamlessly integrated into target MLLMs (e.g., Qwen-VL, InternVL) through lightweight Feature Adapters. Extensive experiments demonstrat e that Uni-DocRobust significantly enhances robust performance on MLLMs and enab les a cost-effective ``pre-train once, deploy everywhere'' paradigm for robust M LLM deployment.

Who Said Neural Networks Aren't Linear?
Nimrod Berman, Assaf Hallak, Assaf Shocher
Neural networks are famously nonlinear. However, linearity is defined relative t o a pair of vector spaces, $f:\mathcal{X}\to\mathcal{Y}$. Leveraging the algebra ic concept of transport of structure, we propose a method to explicitly identify non-standard vector spaces where a neural network acts as a linear operator. Wh en sandwiching a linear operator A between two invertible neural networks, $f(x)=g_y^{-1}(A g_x(x))$, the corresponding vector spaces $\mathcal{X}$ and $\math cal{Y}$ are induced by newly defined addition and scaling actions derived from $ g_x$ and g_y. We term this kind of architecture a Linearizer. This framework m akes the entire arsenal of linear algebra, including SVD, pseudo-inverse, orthog onal projection and more, applicable to nonlinear mappings. Furthermore, we show that the composition of two Linearizers that share a neural network is also a L inearizer. We leverage this property and demonstrate that training diffusion mod els using our architecture makes the hundreds of sampling steps collapse into a single step. We further utilize our framework to enforce idempotency (i.e.\ $f(f (x))=f(x)$) on networks leading to a globally projective generative model and to demonstrate modular style transfer.

CONTEXTOR: Contextualized High-order Contrastive Learning
Ze Cai, Hanzhe Liang, Sihang Zeng, Binbin Zhou, Jun Wen
High-order relations involving multiple interacting entities are commonly encoun tered, particularly in biomedical domains. Existing relational learning methods typically learn static entity representations and assume symmetric relation infe rence, which can be inadequate for capturing context-dependent entity functions and the inherent asymmetry of high-order relations. In this paper, we propose Co ntextualized High-order Contrastive Learning (CONTEXTOR), a general and plug-and -play framework that formulates high-order relation inference as a dynamic query –response process. Specifically, CONTEXTOR decomposes each high-order relation i nto multiple incomplete query tuples and their corresponding response entities. Given a query tuple, we contextualize candidate response entity representations via an asymmetric conditional modulation, and align queries with their correspon ding contextualized responses through multi-fold contrastive learning. Extensive experiments on benchmark datasets spanning multiple biomedical tasks demonstrat

e that CONTEXTOR consistently outperforms existing methods across diverse evalua
tion settings. Code is available at https://github.com/ZJUDataIntelligence/CONTE
XTOR.

Reinforcement Learning for Tool-Calling Agents in Fast Healthcare Interoperabili
ty Resources (FHIR)
Marius Knorr, Robert Müller, Jan Peter Bremer, Nils Schweingruber
Fast Healthcare Interoperability Resources (FHIR) is the dominant standard for i
nteroperable exchange of healthcare data. In FHIR, electronic health records for
m a directed graph of resources. Answering clinically meaningful questions over
FHIR requires agents to perform multi-step reasoning, filtering, and aggregation
 across multiple resource types. Prior work shows that even tool-augmented LLM a
gents (retrieval, code execution, multi-turn planning) often select the wrong re
sources or violate traversal constraints. We study this problem in the context o
f FHIR-AgentBench, a benchmark for realistic question answering over real-world
hospital data, and frame reasoning on FHIR as a sequential decision-making probl
em over a queryable structured graph. We implement a multi-turn CodeAct agent an
d post-train it with reinforcement learning using a custom harness and tools. A
LLM Judge provides execution-grounded rewards. Compared to prompt-based, closed-
model baselines, RL post-training improves performance while enforcing data-inte
grity constraints. Empirically, our approach improves answer correctness from 50
% (o4-mini) to 77% on FHIR-AgentBench using a smaller and cheaper Qwen3-8B model
. We present an end-to-end post-training pipeline (environment building, harness
 construction, model training and custom evaluation) that reliably improves mult
i-turn reasoning over structured clinical graphs.

Influence-Disentangled Federated Training: Learning Models That Are Easy to Unle
arn
Canran Xiao, Qianyu Chen, Liwei Hou
Federated learning increasingly faces deletion requests that require client-leve
l unlearning without sacrificing model quality, yet a client’s influence is ofte
n deeply entangled after many rounds of aggregation. We aim to make unlearning f
ast, stable, and predictable by reducing the gap to leave-one-out retraining und
er realistic heterogeneity. We propose Influence-Disentangled Federated Training
 (IDFT), which instruments standard FedAvg with training-time influence logging:
 each round’s updates are decomposed into shared covarying directions and a clie
nt-separable residual trace, and an entanglement-aware shrinkage suppresses non-
removable components. Deletion then becomes a single subtraction followed by a s
hort anchored repair, yielding a stability-style characterization of retrain fid
elity driven by the unremoved residual. Across representative benchmarks, IDFT c
onsistently attains the lowest retrain gap (Avg. Gap) on multiple dataset--archi
tecture pairs and improves the fidelity--cost frontier, matching retrain-level f
orgetting with substantially lower communication/compute than history-heavy base
lines. These results suggest a practical pathway to unlearning-friendly federate
d systems by designing for removability during training rather than relying sole
ly on post-hoc corrections.
****

FedPAT: Federated Test-Time Adaptation via Prototype Affinity Topology
Shunxin Guo, Jiaqi Lv, Zhiqiang Kou, Shuxia Lin, Xin Geng
Federated Learning (FL) enables privacy-preserving collaboration among distribut
ed clients in open-world environments, but its performance often degrades under
data heterogeneity and unpredictable distribution shifts. Test-Time Adaptation (
TTA) has recently been introduced into FL to leverage unlabeled data from unseen
 clients for online adaptation. However, most existing federated TTA methods emp
loy local feature statistics, which can be brittle under diverse and severe dist
ribution shifts. In this work, we observe that despite significant variations in
 feature distributions, the relational structure among class prototypes—termed *
prototype affinity topology*—remains remarkably stable across heterogeneous clie
nts. Building on this insight, we propose FedPAT, a **Fed**erated TTA framework
that leverages **P**rototype **A**ffinity **T**opology as a cross-client structu

ral prior. FedPAT learns a global PAT by aggregating class prototypes from source clients, capturing consensus inter-class relationships that are robust to local distribution variations. For unseen target clients, we design a topology-aware mechanism that enhances predictions via diffusion of the global PAT, fuses them with parametric outputs, and performs lightweight optimization for robust test-time adaptation. Extensive experiments demonstrate that FedPAT consistently outperforms advanced federated TTA and classical TTA methods across various distribution shifts.

Rethink the Role of Neural Decoders in Quantum Error Correction

Ge Yan, SHANCHUAN LI, Yuxuan Du

Quantum error correction (QEC) is essential for enabling quantum advantages, with decoding as a central algorithmic primitive. Owing to its importance and intrinsic difficulty, substantial effort has been made to QEC decoder design, among which neural decoders have recently emerged as a promising data-driven paradigm. Despite this progress, practical deployment remains hindered by a fundamental accuracy–latency tradeoff, often on the microsecond timescale. To address this challenge, here we revisit neural decoders for surface-code decoding under explicit accuracy–latency constraints, considering code distances up to $d=9$ (161 physical qubits). We unify and redesign representative neural decoders into five architectural paradigms and develop an end-to-end compression pipeline to evaluate their deployability and performance on FPGA hardware. Through systematic experiments, we reveal several previously underexplored insights: (i) near-term decoding performance is driven more by data scale than architectural complexity; (ii) appropriate inductive bias is essential for achieving high decoding accuracy; and (iii) INT4 quantization is a prerequisite for meeting microsecond-scale latency requirements on FPGAs. Together, these findings provide concrete guidance toward scalable and real-time neural QEC decoding.

Realizable Bayes-Consistency for General Metric Losses

Dan Tsir Cohen, Steve Hanneke, Aryeh Kontorovich

We study strong universal Bayes-consistency in the realizable setting for learning with general metric losses, extending classical characterizations beyond 0-1 classification (Bousquet et al., 2021; Hanneke et al., 2021) and real-valued regression (Attias et al., 2024). Given an instance space (X,ρ), a label space (Y,ℓ) with possibly unbounded loss, and a hypothesis class $H \subseteq Y^{X}$, we resolve the realizable case of an open problem presented in Tsir Cohen and Kontorovich (2022). Specifically, we find the necessary and sufficient conditions on the hypothesis class H under which there exists a distribution-free learning rule whose risk converges almost surely to the best-in-class risk (which is zero) for every realizable data-generating distribution. Our main contribution is this sharp characterization in terms of a combinatorial obstruction: Similarly to Attias et al. (2023), we introduce the notion of an infinite non-decreasing (γ_k)-Littlestone tree, where $\gamma_k \to \infty$. This extends the Littlestone tree structure used in Bousquet et al. (2021) to the metric loss setting.

Unbiased Dynamic Pruning for Efficient Group-Based Policy Optimization

Haodong Zhu, Yangyang Ren, Yanjing Li, Mingbao Lin, Linlin Yang, Xuhui Liu, Xiantong Zhen, haiguang liu, Baochang Zhang

Group Relative Policy Optimization (GRPO) effectively scales LLM reasoning but incurs prohibitive computational costs due to its extensive group-based sampling requirement.

While recent selective data utilization methods can mitigate this overhead, they could induce estimation bias by altering the underlying sampling distribution, compromising theoretical rigor and convergence behavior.

To address this limitation, we propose Dynamic Pruning Policy Optimization (DPPO), a framework that enables dynamic pruning while preserving unbiased gradient estimation through importance sampling-based correction.

By incorporating mathematically derived rescaling factors, DPPO significantly ac

celerates GRPO training without altering the optimization objective of the full-batch baseline.
Furthermore, to mitigate the data sparsity induced by pruning, we introduce Dense Prompt Packing, a window-based greedy strategy that maximizes valid token density and hardware utilization.
Extensive experiments demonstrate that DPPO consistently accelerates training across diverse models and benchmarks.
For instance, on Qwen3-4B trained on MATH, DPPO achieves 2.37$\times$ training speedup and outperforms GRPO by 3.36\% in average accuracy across six mathematical reasoning benchmarks.
****

MCCE: A Framework for Multi-LLM Collaborative Search in Discrete Spaces with Similarity-Filtered Preference Learning
Nian Ran, Zhongzheng Li, Yue Wang, Qingsong Ran, Xiaoyuan Zhang, Shikun Feng, Richard Allmendinger, Xiaoguang Zhao
Multi-objective discrete optimization problems, such as molecular design, pose significant challenges due to their vast and unstructured combinatorial spaces. Traditional evolutionary algorithms often get trapped in local optima, while expert knowledge can provide crucial guidance for accelerating convergence. Large language models (LLMs) offer powerful priors and reasoning ability, making them natural optimizers when expert knowledge matters. However, closed-source LLMs, though strong in exploration, cannot update their parameters and thus cannot internalize experience. Conversely, smaller open models can be continually fine-tuned but lack broad knowledge and reasoning strength. We introduce Multi-LLM Collaborative Co-evolution (MCCE), a hybrid framework that unites a frozen closed-source LLM with a lightweight trainable model. The system maintains a trajectory memory of past search processes; the small model is progressively refined via reinforcement learning, with the two models jointly supporting and complementing each other in global exploration. Unlike model distillation, this process enhances the capabilities of both models through mutual inspiration. Experiments on multi-objective drug design benchmarks show that MCCE achieves state-of-the-art Pareto front quality and consistently outperforms baselines. These results highlight a new paradigm for enabling continual evolution in hybrid LLM systems, combining knowledge-driven exploration with experience-driven learning.
The code of MCCE is available on https://github.com/lzz-z/MCCE

Efficient, Validation-Free Intrinsic Quality Estimation for Large-Scale Face Recognition Datasets
Zhichao Chen, Yongle Zhao, Kaicheng Yang, Meng Yang, Yin Xie, Ziyong Feng
We propose Intrinsic Quality (IQ), a validation-free metric designed to estimate the inherent potential of face recognition (FR) datasets to produce high-performance models without the need for full-scale training. IQ integrates two components: (i) a Neighbor-Consistency Score that quantifies local identity label agreement via nearest neighbors, and (ii) Global Representation Subspace Complexity (Effective Rank, ER), which captures the underlying embedding geometry and dataset diversity. IQ allows for rapid evaluation using lightweight proxy models or data subsets, facilitating dataset diagnosis and curation prior to resource-intensive full-scale training. We describe an experimental protocol tailored to clean, noisy, and mixed■quality FR datasets, and outline evaluation methodologies to validate IQ’s predictive power for downstream performance.
****

SPLIT-VLM: Salience-Guided Partitioning towards Local Coverage for Importance-Aware Token Dropping in Vision-Language Models
Seungil Lee, Gilha lee, Hyun Kim
Large-scale vision–language models (VLMs) excel at multimodal reasoning, yet efficiency collapses when vision tokens—often orders of magnitude more than text—dominate compute and memory. Prior token-reduction strategies typically trade off salience (which is prone to position bias and incurs extra computation) against diversity (which can under-cover salient regions and is sensitive to hyperparameters). We present SPLIT, a theoretically grounded framework that jointly preserv

es salience and diversity while aggressively eliminating redundancy. SPLIT (i) e stimates token importance via temporal shifts of hidden states across layers—esc hewing attention scores and their biases; (ii) assigns adaptive region-level bud gets to guarantee localized coverage; and (iii) selects tokens using a diversity score that prioritizes distinctive, non-redundant representations. Our analysis shows that adaptive budgeting yields tighter coverage guarantees than uniform a llocation, and our selection rule maintains diversity without costly tuning. Emp irically, SPLIT consistently outperforms state-of-the-art on image and video und erstanding benchmarks. On image understanding with LLaVA-1.5-7B, SPLIT preserves over 99\% accuracy with 192 vision tokens and about 92.8\% with only 64 tokens, demonstrating robust performance under severe token budgets. These results indi cate that SPLIT delivers scalable, attention-score-free token reduction that mak es multimodal reasoning substantially more efficient without sacrificing accurac y.

Unleashing the Representational Power of Fourier Shapes for Attacking Infrared O bject Detection

Yixing Yong, Jian Wang, Ming Lei, Lijun He, Fan Li

Infrared object detection is crucial for perception in autonomous driving and su rveillance but remains vulnerable to physical adversarial attacks. Unlike in the RGB domain, where attacks rely on color texture, infrared attacks must manipula te thermal signatures, making the geometry shape of heat-blocking materials the primary adversarial information carrier. Current shape-based methods suffer from a fundamental trade-off between representational capability and optimization po wer, limiting their attack effectiveness.

In this work, we overcome this dilemma by introducing learnable Fourier shapes t o the infrared domain. We utilize an end-to-end differentiable framework where a compact set of Fourier coefficients, defining the shape boundary, is analytical ly mapped to a pixel-space mask via the winding number theorem. This enables eff icient gradient-based optimization to generate potent shapes that cause human ta rgets to evade detection. Extensive digital and physical experiments provide a c omprehensive evaluation and validate our superior performance. Our resulting phy sical patch achieves striking robustness, successfully evading detectors across diverse distances, angles, poses, and individuals, and achieves over 88% attack success rate at distances greater than 25m (conf.=0.5). Code is available at htt ps://github.com/Yongyx99/Fourier-shape-attack.

Geometric Coherence Learning for Structuring Value Functions in Plain MDPs

Zuyuan Zhang, Zeyu Fang, Tian Lan

Geometric properties can be leveraged to stabilize and speed reinforcement learn ing. Existing examples include encoding symmetry structure, geometry-aware data augmentation, and enforcing structural restrictions. In this paper, we take a no vel view of RL through the lens of order theory and recast value function estima tes into learning a desired poset (partially ordered set).

We propose \emph{GCR-RL} (Geometric Coherence Regularized Reinforcement Learning) that computes a sequence of super-poset refinements -- by refining posets in p revious steps and learning additional order relationships from temporal differen ce signals -- thus ensuring geometric coherence across the sequence of posets un derpinning the learned value functions. Two novel algorithms by Q-learning and by actor--critic are developed to efficiently realize these super-poset refineme nts. Their theoretical properties and convergence rates are analyzed. We empiric ally evaluate GCR-RL in a range of tasks and demonstrate significant improvement s in sample efficiency and stable performance over strong baselines.

Rethinking Graph Transformers as Graph Signal Denoisers: The Role of Block-Diago nal Priors

Jiaming Zhuo, Ziyi Ma, Kun Fu, Di Jin, Chuan Wang, Zhen Wang, Xiaochun Cao, Huaz hu Fu, Liang Yang

By synergizing graph topology with the global expressive power of attention, Gra ph Transformers (GTs) have emerged as a powerful architecture for node classific

ation. Existing GTs mainly focus on diverse topology injection paradigms, which fundamentally construct different propagation operators. However, a unified theoretical understanding of what constitutes a desirable propagation operator remains largely unexplored. To bridge this gap, this paper rethinks GTs from a graph signal denoising perspective, revealing that a block-diagonal structure is a desirable structural prior for graph denoising. To efficiently instantiate this prior, this paper introduces BDFormer, which imposes spectral block regularization on the affinity of a compact set of latent anchors. Furthermore, by introducing hard assignments between nodes and anchors, BDFormer establishes sparse, structured propagation that suppresses noisy cross-class propagation in linear time. Meanwhile, the learned global affinity guides the pruning of inter-class edges in the graph topology, enabling both global and local propagation to jointly adhere to the target block-diagonal structure. Extensive experiments on benchmark datasets demonstrate the superiority and scalability of BDFormer.

ThreadWeaver: Adaptive Threading for Efficient Parallel Reasoning in Language Models
Long Lian, Sida Wang, Felix Juefei-Xu, Tsu-Jui Fu, Xiuyu Li, Adam Yala, Trevor Darrell, Alane Suhr, Yuandong Tian, Xi Victoria Lin
Scaling inference-time computation has enabled Large Language Models (LLMs) to achieve strong reasoning performance, but their inherently sequential decoding incurs substantial latency, motivating parallelization of the generation process. However, existing parallel reasoning approaches suffer from performance degradation compared to their sequential counterparts, and often rely on specialized inference engines. We introduce ThreadWeaver, a framework for adaptive parallel reasoning that matches the accuracy of comparably sized sequential reasoning models while significantly reducing inference latency via three key innovations: 1) a two-stage parallel trajectory generator that produces high-quality parallel chain-of-thought data for supervised fine-tuning; 2) a trie-based rollout design that enables parallel reasoning on any off-the-shelf autoregressive inference engine; and 3) a parallelization-aware reinforcement learning framework that trains the model to balance reasoning accuracy with effective parallelization. Across six challenging math reasoning benchmarks, ThreadWeaver trained on top of Qwen3-8B achieves performance on par with cutting-edge sequential reasoning models (79.9% on AIME24 and 71.9% on average) while delivering up to 1.53x speedup in token latency, establishing a new Pareto frontier between accuracy and efficiency.
****

Clustered Influence Functions
Miklós Máté Badó, Kristian Fenech
Influence functions are a standard tool for data debugging and unlearning, but they become impractical for **high-query** subset workloads such as large-K cross-validation, repeated resampling, or interactive what-if analysis as each subset query typically requires an expensive inverse-curvature solve. We introduce **Clustered Influence Functions (CiF)**, which turns subset influence into an **amortized subset oracle**. We build a compact cache once by clustering training gradients, solve a damped Generalised Gauss-Newton system only for cluster means, and answer new subset queries by a linear recombination using cluster membership counts. This yields per-query cost of $O(Cp)$ linear in the cache size C, and the number of model parameters p. We further provide a diagnostic error bound that decomposes approximation error into a **clustering scatter** term and a **solver residual** term, making the accuracy-compute tradeoff explicit through the cache budget and solver tolerance. Evaluations across MNIST, CIFAR-10 show that CiF matches per-query influence rankings while significantly reducing the total runtime in high-Q regimes, enabling influence-based workflows that are otherwise computationally prohibitive.
****

Maximum Likelihood Reinforcement Learning
Fahim Tajwar, Guanning Zeng, Yueer Zhou, Yuda Song, Daman Arora, Yiding Jiang, Jeff Schneider, Ruslan Salakhutdinov, Haiwen Feng, Andrea Zanette
Reinforcement learning (RL) is the method of choice for training models in setup

s where the objective function can only be evaluated by sampling from the model. Our key observation is that when the feedback is terminal and binary, models implicitly induce a likelihood over correct rollouts. Maximum likelihood would be the natural framework in such settings, but RL is used instead as a workaround to the non-differentiability. We prove that the standard, expected-reward RL formulation is only a first-order approximation of the likelihood. To remedy this mismatch, we introduce **Maximum Likelihood Reinforcement Learning (MaxRL)**, a compute-indexed family of sample-based objectives that interpolate between expected-reward RL and maximum likelihood as sampling compute is scaled. The resulting objective is a one-line change to standard RL implementations. MaxRL Pareto-dominates existing methods in all tested models and tasks, achieves up to $\mathbf{20\times}$ gains in test-time scaling efficiency over GRPO, and scales more favorably with additional training data and compute.
****

Unified Multimodal Visual Tracking with Dual Mixture-of-Experts
Lingyi Hong, Jinglun Li, Xinyu Zhou, Kaixun Jiang, Pinxue Guo, Zhaoyu Chen, Runze Li, Xingdong Sheng, Wenqiang Zhang
Multimodal visual object tracking can be divided into to several kinds of tasks (e.g. RGB and RGB+X tracking), based on the input modality. Existing methods often train separate models for each modality or rely on pretrained models to adapt to new modalities, which limits efficiency, scalability, and usability. Thus, we introduce OneTrackerV2, a unified multi-modal tracking framework that enables end-to-end training for any modality. We propose Meta Merger to embed multi-modal information into a unified space, allowing flexible modality fusion and robustness. We further introduce Dual Mixture-of-Experts (DMoE): T-MoE models spatiotemporal relations for tracking, while M-MoE embeds multi-modal knowledge, disentangling cross-modal dependencies and reducing feature conflicts. With a shared architecture, unified parameters, and a single end-to-end training, OneTrackerV2 achieves state-of-the-art performance across five RGB and RGB+X tracking tasks and 12 benchmarks, while maintaining high inference efficiency. Notably, even after model compression, OneTrackerV2 retains strong performance. Moreover, OneTrackerV2 demonstrates remarkable robustness under modality-missing scenarios.
****

KAST-BAR: Knowledge-Anchored Semantically-Dynamic Topology Brain Autoregressive Modeling for Universal Neural Interpretation
Haoning Wang, Wenchao Yang, Shuai Shen, Yang Li
While EEG foundation models have shown significant potential in universal neural decoding across tasks, their advancement remains constrained by the inadequacy modeling of *complex spatiotemporal topology*, as well as the inherent *modality gap* between low-level physiological signals and high-level textual semantics.

To address these challenges, we propose a **K**nowledge-**A**nchored **S**emantically-Dynamic **T**opology **B**rain **A**uto**r**egressive Model (KAST-BAR), which dynamically aligns physiological representations derived from multi-level brain topology with an expert-level semantic space.

Specifically, we design a Dual-Stream Hierarchical Attention (DSHA) encoder that accurately captures the brain's intrinsic non-Euclidean topology by modeling local temporal dynamics with global spatial contexts.

On this basis, a Knowledge-Anchored Semantic Profiler (KASP) is proposed to synthesize physically-grounded and instance-level textual profiles, which subsequently drive a Semantic Text-Aware Refiner (STAR) to dynamically reconstruct EEG representations using Latent Expert Queries.

By conducting large-scale pre-training on 21 diverse datasets to build a foundation model, KAST-BAR effectively integrates expert-level medical knowledge into EEG signal representations, consistently achieving state-of-the-art performance across six downstream tasks. Our code is available at https://github.com/KAST-BAR/KAST-BAR
****

Crowd4D: Scene-Aware Monocular 4D Crowd Reconstruction
Hongbo Kang, Tianyi Zhou, Qingyang Yang, Hongwei Wen, Jing Huang, Yu-Kun Lai, Kun Li

Recovering scene-consistent 4D crowd motion from monocular video in large-scale scenes remains challenging due to severe depth ambiguity and complex scene geometry. Existing monocular crowd reconstruction methods typically rely on single-plane assumptions, leading to unreliable metric scale and spatial drift under complex terrain. We propose Crowd4D, the first scene-aware 4D crowd reconstruction framework that jointly optimizes the crowd and scene from a monocular RGB video in large-scale scenes. Crowd4D explicitly incorporates scene geometry and ensures consistency across image and scene spaces via a multi-stage optimization strategy. A key bottleneck of this task lies in accurate human–scene alignment, particularly in scale and position. However, human and scene reconstructions are typically decoupled. To address this, we introduce the Human–Scene Interaction Proxy (HSIP) as an intermediate representation, derived from Scene Interaction Point Clouds and a Scene Interaction Surface (SIPC\&SIS), which encode explicit scene-aware geometric priors and redefine the optimization space for large-scale monocular 4D crowd reconstruction. To further improve temporal stability under occlusions, we introduce Crowd Structural Coherence Regularization (CSCR), which leverages HSIP-based spatial priors to impose soft temporal consistency on pairwise relative displacements and directions within local crowd neighborhoods. Extensive experiments demonstrate that Crowd4D consistently outperforms existing state-of-the-art methods and enables robust monocular 4D crowd reconstruction in complex, large-scale real-world scenes. Project page is available at https://cic.tju.edu.cn/faculty/likun/projects/Crowd4D.

SkelHCC: A Hyperbolic CLIP-Driven Cache Adaptation Framework for Skeleton-based One-Shot Action Recognition

Yanan Liu, Anqi Zhu, Jingmin Zhu, Jun Liu, Hossein Rahmani, Mohammed Bennamoun, Farid Boussaid, Dan Xu, Qiuhong Ke

Skeleton-based action recognition aims to understand human behaviors from body joint sequences and is especially challenging in the one-shot setting, where only a single labeled exemplar is available for each novel action. A key challenge is learning representations that capture the hierarchical and compositional structure of human motion while aligning effectively with high-level action semantics under extreme data scarcity. Existing approaches, largely based on Euclidean embeddings and low-level motion cues, struggle to model the tree-like organization of skeleton data, limiting cross-modal alignment and generalization to unseen action categories.

We propose SkelHCC, a unified skeleton hyperbolic CLIP-driven cache adaptation framework for one-shot skeleton-based action recognition. SkelHCC introduces an Explicitly Hierarchical Hyperbolic CLIP (EH-HCLIP) module that embeds skeleton sequences and action language into a shared hyperbolic space. By leveraging the negative curvature and exponential volume growth of hyperbolic geometry, EH-HCLIP naturally encodes the joint–part–body hierarchy of human anatomy and yields structurally consistent cross-modal representations. To support efficient one-shot adaptation, SkelHCC further integrates a training-free LLM-guided Multi-granularity Voting Cache (LMV-Cache) for context-aware inference. Experiments on NTU RGB+D 60, NTU RGB+D 120, and PKU-MMD II demonstrate that SkelHCC consistently outperforms state-of-the-art methods. Code will be available at https://github.com/lya19971103/SkelHCC

From Coarse to Fine: Deep Prototype Refinement Network for Few-Shot Point Cloud Semantic Segmentation

Changshuo Wang, Weijun Li, Shuting He, Xiang Fang, Xingyu Gao, Zhonghang Liu, Prayag Tiwari, Dimitrios Kanoulas

Few-shot point cloud semantic segmentation (FS-PCSS) aims to achieve precise segmentation of novel categories using only limited labeled samples. Existing prototype-based methods rely on shallow feature fusion, failing to adequately model the feature distribution shift between support and query sets, resulting in insufficient prototype adaptation. To address this, we propose the Deep Prototype Refinement Network (DPR-Net), which systematically achieves progressive adaptation by constructing a coarse-to-fine prototype evolution trajectory. Our core Dynami

c Prototype Refinement (DPR) module decomposes features into common and distinct ive subspaces based on channel activation, enabling targeted adjustment of domai n-sensitive features while preserving class-shared semantics. By cascading multi ple refinement modules, we construct a prototype trajectory transitioning from s upport-biased to query-adapted representations, mitigating both under- and over- adaptation. Furthermore, our Mixture of Prototype Experts (MoPE) mechanism treat s prototypes at different stages as experts and ensembles their predictions thro ugh confidence-driven weighting. Extensive experiments demonstrate state-of-the- art performance with high efficiency. Our code will be available at https://gith ub.com/changshuowang/DPR-Net.

GEM-FI: Gated Evidential Mixtures with Fisher Modulation
Marco Mustafa Mohammed, Fatemeh Daneshfar, Pietro Lio
Evidential Deep Learning (EDL) enables single-pass uncertainty estimation by pre dicting Dirichlet evidence, but it can remain overconfident and poorly calibrate d, and it often fails to represent multi-modal epistemic uncertainty. We introdu ce Gated Evidential Mixtures (GEM), a family of models that learns an in-model e nergy signal and uses it to gate evidential outputs end-to-end in a distance-inf ormed manner. GEM-CORE learns a feature-level energy and maps it to a bounded ga te that smoothly suppresses evidence when support is low. To capture epistemic m ulti-modality without multi-pass ensembling, GEM-MIX adds a lightweight mixture of evidential heads with learned routing weights while preserving single-pass in ference. Finally, GEM-FI stabilizes mixture allocations via a Fisher-informed re gularizer, reducing head collapse and producing smoother boundary uncertainty. A cross image classification and OOD detection benchmarks, GEM improves calibratio n and ID/OOD separation with single-pass inference. On CIFAR-10, GEM-FI vs. DAED L improves Acc. from 91.11 to 93.75 (+2.64 pp), reduces Brier ×100 from 14.27 to 6.81 (−7.46), and also improves misclassification-detection (AUPR) from 99.08 t o 99.94 (+0.86). For epistemic OOD detection, GEM-FI achieves AUPR/AUROC of 92.5 9/95.09 on CIFAR-10→SVHN and 90.20/89.06 on CIFAR-10→CIFAR-100 (vs. 85.54/89.30 and 88.19/86.10 for DAEDL).

Benchmarking the Limits of In-Context Reinforcement Learning for Ad-Hoc Teamwork
Yuheng Jing, Kai Li, Jiajun Zhang, Zeyao Ma, Jiaxi Yang, Lei Zhang, Zhe Wu, Jinm in He, Junliang Xing, Jian Cheng
In-Context Reinforcement Learning (ICRL) has enabled foundation agents to adapt instantaneously to novel tasks, yet its efficacy in Ad-Hoc Teamwork (AHT)—where coordination with unknown partners is required—remains unexplored. To rigorously evaluate this, we introduce a large-scale benchmark **ICRL4AHT**, built upon a high-throughput JAX implementation of Overcooked-V2. Our benchmark includes a la rge, diverse teammate suite spanning both RL and heuristic policies, enabling co ntrolled train-test shifts, and provides a reproducible end-to-end pipeline for teammate generation, learning-history collection, dataset construction, and onli ne multi-episode evaluation. We evaluate representative history-conditioned ICRL algorithms, including Algorithm Distillation (AD) and Decision-Pretrained Trans former (DPT), across millions of transitions. Results reveal notable limitations : contrary to their success in single-agent domains, these baselines fail to exh ibit robust test-time adaptation in multi-agent settings. Specifically, these me thods frequently underperform random baselines across both unseen teammate and u nseen layout tracks, with no clear in-context improvement over long horizons. Th ese findings highlight the challenges of strategic inference under partial obser vability within the OvercookedV2 AHT protocol, establishing our benchmark as a c ritical testbed for next-generation coordination algorithms.

Leveraging Gauge Freedom for Learning Non-Gradient Population Dynamics of Stocha stic Systems
Jules Berman, Tobias Blickhan, Benjamin Peherstorfer
In existing works on population dynamics inference, there is a focus on flows ar ising from vector fields that are the gradients of scalar potentials. Among all admissible flows that are compatible with the population dynamic, gradient flows

are optimal in a specific sense: they minimize kinetic energy. The selection of fields based on different criteria corresponds to a gauge freedom when determining population dynamics, which we leverage in this work. We propose Non-Gradient Inference Flows (NGIF), an algorithm to infer non-gradient population dynamics using a weak formulation of the continuity equation. This allows us to parameterize with general vector fields as well as choose other selection criteria beyond minimal energy. We demonstrate on a variety of low- and high-dimensional physics problems that this more general approach improves distributional accuracy over gradient-restricted baselines and better captures non-potential transport.

Listening Through the Noise: Cauchy-Driven Diffusion Bridges for Robust Gastrointestinal Auscultation and Clinical Benchmarking

Dian Ding, Liren Dong, Yu Lu, Juntao Zhou, Ran Wang, Peng Li, Zhenyi Jia, Guangtao Xue

Gastrointestinal (GI) motility assessment via bowel sounds (BS) offers a non-invasive alternative to resource-intensive clinical standards. However, the diagnostic utility of BS is often compromised by its spectral overlap with non-stationary speech interference. While generative models have advanced signal restoration, traditional Gaussian-based diffusion frameworks struggle with the impulsive, heavy-tailed nature of real-world clinical noise. In this paper, we propose a novel Cauchy-driven Diffusion Bridge framework to isolate high-fidelity bowel sounds from complex interference. Our contributions are three-fold: (1) We introduce ClinBS, a large-scale clinical dataset (over 25 hours) containing rare pathological transients verified by experts; (2) We mathematically formulate a Cauchy bridge driver, deriving closed-form expressions for the score and density to better model heavy-tailed perturbations; and (3) We implement an efficient sampling procedure via Gaussian scale-mixture reparameterization. Extensive experiments show our framework achieves state-of-the-art performance, outperforming baselines by 13.4%–49.8% across core metrics and elevating abnormal BS recognition accuracy to 88.01%. These results demonstrate the system's potential for robust clinical GI monitoring and diagnosis.
****

Weasel: Out-of-Domain Generalization for Web Agents via Importance-Diversity Data Selection

Fatemeh Pesaran Zadeh, Seyeon Choi, Xing Han Lù, Siva Reddy, Gunhee Kim

Large language models (LLMs) have enabled web agents that follow natural language goals through multi-step browser interactions. However, agents fine-tuned on specific trajectories and domain often struggle to generalize out of domain, and offline training can be compute-inefficient due to noisy, redundant trajectories and long accessibility-tree (AXTree) states. To address both issues, we propose Weasel, a trajectory selection method for offline training of web agents. Weasel selects a fixed-budget subset of trajectory steps by optimizing an objective that balances unary importance with pairwise diversity over states, websites, and interaction patterns, solving efficiently with a greedy algorithm. We further improve efficiency with target-centered AXTree pruning that keeps only content around the ground-truth action target, and we mitigate style mismatch for reasoning-native models by replacing expert traces with model-generated, style-consistent rationales. Across AgentTrek and NNetNav training datasets, evaluations in WebArena, WorkArena, and MiniWob, and experiments with Qwen2.5-7B, Gemma3-4B, and Qwen3-8B, Weasel improves out-of-domain performance while reducing training cost, producing roughly 9.7-12.5$\times$ training speedups over standard fine-tuning. We make the code available at https://github.com/fatemehpesaran310/weasel.

Evaluating Sample Utility for Efficient Data Selection by Mimicking Model Weights

Tzu-Heng Huang, Manjot Bilkhu, John Cooper, Frederic Sala, Javier Movellan

Large-scale web-crawled datasets contain noise, bias, and irrelevant information, necessitating data selection techniques. Existing methods depend on hand-crafted heuristics, downstream datasets, or require expensive influence-based computations---all of which limit scalability and introduce unwanted data dependencies.

To address this, we introduce the Mimic Score, a simple and geometry-based data-quality metric that evaluates utility by measuring alignment between a sample's gradients and a target direction induced by a pre-trained reference model. This leverages readily available model weights, avoids needing validation datasets, and incurs minimal computational overheads. Building on this metric, we propose Grad-Mimic, a two-stage framework that re-weights samples online to accelerate training and aggregates sample utilities offline to construct effective data filters. Empirically, we show that using mimic scores to guide training improves data efficiency, accelerates convergence, yields consistent performance gains across six image datasets, and enhances CLIP models with 20.7\% fewer training steps. Additionally, mimic score-based filters augment existing filtering techniques, enabling improved CLIP models trained with 4.7 million fewer samples.

Motion Dynamics Learning for Few-Shot Embodied Adaptation

Sibo He, Weiying Xie, Daixun Li, Junhao Zhong, Jiayun Tian, Yunke Wang, Leyuan Fang, Gang He, Yunsong Li

Vision-Language-Action (VLA) models have shown strong potential for robotic manipulation, yet adapting pretrained models to novel tasks typically relies on substantial task-specific demonstrations, limiting scalability.

Current VLA methods mostly focus on action imitation, which ignores the richer structure contained in trajectories. In contrast, motion dynamics governing how actions evolve over time are more informative and transferable, making them better suited for few-shot adaptation.

Motivated by this idea, we propose DynVLA, a few-shot adaptation system that reformulates VLA learning from action imitation to trajectory-level motion dynamics modeling.

Specifically, we propose Motion Dynamics Mechanism (MDM), which distills latent embeddings from trajectories via flow-matching inversion, yielding compact representations that capture dynamics.

We further design Dynamics-Constrained Modeling (DCM). DCM projects these inferred representations onto a Dynamics Bank, which stores prior motion knowledge pretrained from diverse demonstrations. By grounding action generation in these learned priors, the system enables interpolating between existing action paradigms to represent novel dynamics modes.

Experiments on 13 real-world tasks demonstrate that DynVLA outperforms existing SOTA systems by 15.8\% in average success rate with around 20 demonstrations, highlighting its adaptation capabilities in real-world scenes. Our code is available at https://github.com/trantor2nd/Motion-DynVLA.

****

HyPOLE: Hyperproperty-Guided Multi-Agent Reinforcement Learning under Partial Observation

Arshia Rafieioskouei, Tzu-Han Hsu, Matthew Lucas, Borzoo Bonakdarpour

Formal specification is a powerful tool to guide the learning process and provides significant advantages over reward shaping: (1) mathematical rigor; (2) expressiveness to specify objectives and constraints, and (3) the ability to define tactics to achieve objectives. However, these benefits remain largely unexplored in the context of Multi-Agent Reinforcement Learning (MARL). This paper introduces HyPOLE, a novel framework for MARL under partial observability, where learning is guided by the expressive power of the so-called hyperproperties and, in particular, the temporal logic HyperLTL. We integrate Centralized Training for Decentralized Execution (CTDE) techniques with HyPOLE to synthesize decentralized policies, and our evaluation on SMAC, MessySMAC, and WildFire benchmark demonstrates clear advantages over baselines.

Bipartite Graph Attention-based Clustering for Large-scale scRNA-seq Data

Zhuomin Liang, Liang Bai, Xian Yang

scRNA-seq clustering is a critical task for analyzing single-cell RNA sequencing (scRNA-seq) data, as it groups cells with similar gene expression profiles. Transformers, as powerful foundational models, have been applied to scRNA-seq clustering. Their self-attention mechanism automatically assigns higher attention wei

ghts to cells within the same cluster, enhancing the distinction between clusters. Existing methods for scRNA-seq clustering, such as graph transformer-based models, treat each cell as a token in a sequence. Their computational and space complexities are $\mathcal{O}(n^2)$ with respect to the number of cells, limiting their applicability to large-scale scRNA-seq datasets. To address this challenge, we propose a Bipartite Graph Transformer-based clustering model (BGFormer) for scRNA-seq data. We introduce a set of learnable anchor tokens as shared reference points to represent the entire dataset. A bipartite graph attention mechanism is introduced to learn the similarity between cells and anchor tokens, bringing cells of the same class closer together in the embedding space. BGFormer achieves linear computational complexity with respect to the number of cells, making it scalable to large datasets. Experimental results on multiple large-scale scRNA-seq datasets demonstrate the effectiveness and scalability of BGFormer.

Lie-Algebraic Acceleration of Neural Koopman Dynamics
Jongwon Lee, Jiwoong Kim, Jungwoo Park, Sungwoo Park
We present a Lie-algebraic approach to model Koopman dynamics that integrates algebraic structure with computational scalability.
The proposed formulation constrains the neural generators to evolve within prescribed Lie subalgebras and constructs finite-time flows through a neural Magnus expansion construction, thereby maintaining consistency with the associated Lie-group composition over each time segment. To address the computational burden inherent in sequential propagation, we exploit the associativity of Lie-group compositions and construct segmentwise propagators via a prefix-scan algorithm, which reduces the depth of temporal composition from linear to logarithmic. Consequently, the framework enables accurate long-horizon prediction while improving computational efficiency, and provides a principled foundation for scalable Koopman operator learning for nonlinear systems.

CoverPruneGS: Coverage-Preserving Structured Pruning for Hierarchical 3D Gaussian Splatting from Sparse-View Monocular Videos
Yang Xiao, Guoan Xu, Guxue Gao, Qiang Wu, Wenjing Jia
Reconstructing complete yet compact 3D Gaussian Splatting (3DGS) representations from sparse-view monocular videos remains a significant challenge. While hierarchical training with Video Frame Interpolation (VFI) improves coverage, its correlated pseudo-views and repeated merging accumulate structured, non-i.i.d. redundancy, violating the implicit independence assumptions of standard pruning methods and rendering global thresholding ineffectual. We propose CoverPruneGS, a coverage-preserving structured pruning framework specifically designed for hierarchical 3DGS. Our approach implements a coarse-to-fine pruning pipeline using voxel-based local diversity selection and ground-truth-guided lazy refinement via randomized dropout rendering. To ensure reliable refinement, we introduce a footprint-aware CUDA attribution mechanism. By aggregating ground-truth-aligned error degradation across Gaussian-influenced pixels, we generate faithful importance scores that enable precise, quantile-based "rescue" of essential primitives. Experimental results across multiple datasets demonstrate that CoverPruneGS substantially reduces Gaussian counts by 56.8\% and significantly accelerates inference speeds, all while enhancing or maintaining the quality of novel view synthesis.

DART: Distribution-Aware Adaptive Relational Transfer for Adversarial Attacks against Closed-Source MLLMs
Kaidi Hu, Guancheng Wan, Xiao Luo, Ruigang Yang
This paper studies the critical problem of targeted adversarial attacks against closed-source MLLMs, which aim to generate highly transferable adversarial samples with open-source MLLMs. Previous approaches typically focus on maximizing the similarity of latent representations between adversarial samples and target samples. However, these approaches could overfit specific target samples with severely limited generalization ability to closed-source MLLMs. Towards this end, we propose a novel approach named Distribution-aware Adaptive Relational Transfer (DART) for adversarial attacks against closed-source MLLMs. The core of our DART

is to adopt a statistical lens to characterize the intrinsic semantics of images for more generalized and robust alignment. In particular, each augmented image is considered an example from the intrinsic distribution of the original image. Then, we utilize non-parametric Energy Distance to measure the distribution divergence, which is naturally adopted for the semantic alignment in the hidden space. To further enhance transferability to specific target models, we learn a graph neural network (GNN) to explore the complex relations between source and target MLLMs on transferability and adaptively select surrogate models to maximize transferability across diverse targets. Extensive experiments on benchmark datasets validate the superior robustness and effectiveness of the proposed DART in comparison to various competing baselines.

KORE: Enhancing Knowledge Injection for Large Multimodal Models via Knowledge-Oriented Controls
Kailin Jiang, Hongbo Jiang, Ning Jiang, Zhi Gao, Jinhe Bi, Yuchen Ren, Bin Li, Yuntao Du, Lei Liu, Qing Li
Large Multimodal Models encode extensive factual knowledge in their pre-trained weights. However, its knowledge remains static and limited, unable to keep pace with real-world developments, which hinders continuous knowledge acquisition. Effective knowledge injection thus becomes critical, involving two goals: knowledge adaptation (injecting new knowledge) and knowledge retention (preserving old knowledge). Existing methods often struggle to learn new knowledge and suffer from catastrophic forgetting. To address these challenges, we propose KORE, a synergistic method centered around KnOwledge-oRientEd controls. These controls are implemented through a two-stage optimization process: (1) KORE automatically converts individual knowledge items into structured and comprehensive knowledge to ensure that the model accurately learns new knowledge, enabling accurate adaptation. (2) KORE stores previous knowledge in the covariance matrix of LMM's linear layer activations and initializes the adapter by projecting the original weights into the matrix's null space, defining a fine-tuning direction that minimizes interference with previous knowledge, enabling powerful retention. Extensive experiments on various LMMs, including LLaVA-v1.5 (7B), LLaVA-v1.5 (13B), and Qwen2.5-VL (7B), show that KORE achieves superior new knowledge injection performance and effectively mitigates catastrophic forgetting.

Towards Optimal Robustness in Learning-Augmented Paging
Peng Chen, Hailiang Zhao, Xueyan Tang, Yixuan Wang, Shuiguang Deng
Learning-augmented paging has been extensively studied in recent years. A key advantage over naive ML-based approaches is bounded robustness, which guarantees worst-case performance even when predictions are inaccurate, making these algorithms valuable for real-world systems. Prior work achieves robustness bounds of $2H_k + O(1)$ in the randomized setting, leaving a gap to the optimal competitive ratio H_k.

In this paper, we study how to close this gap. We begin by reviewing online optimality and proving a new property of the latest H_k-competitive algorithm, which facilitates our analysis in the learning-augmented setting. Then, we review existing learning-augmented paging algorithms and introduce a unifying primitive, the relative prediction budget, which captures the essence of establishing robustness and reveals that prior algorithms either overuse or underutilize predictions. Guided by the above analysis, we develop a new framework that achieves the best-possible robustness up to an additive constant for learning-augmented paging: $H_k + O(1)$. Experiments further demonstrate strong practical performance.
****

WebWorld: A Large-Scale World Model for Web Agent Training
Zikai Xiao, Jianhong Tu, Chuhang Zou, Yuxin Zuo, Zhi Li, Peng Wang, Bowen Yu, Fei Huang, Junyang Lin, Zuozhu Liu
Web agents require massive trajectories to generalize, yet real-world training is constrained by network latency, rate limits, and safety risks. We introduce \textbf{WebWorld} series, the first open-web simulator trained at scale. While exi

sting simulators are restricted to closed environments with thousands of trajectories, WebWorld leverages a scalable data pipeline to train on 1M+ open-web interactions, supporting reasoning, multi-format data, and long-horizon simulations of 30+ steps.
For intrinsic evaluation, we introduce WebWorld-Bench with dual metrics spanning nine dimensions, where WebWorld achieves simulation performance comparable to Gemini-3-Pro. For extrinsic evaluation, Qwen3-14B trained on WebWorld-synthesized trajectories improves by +9.2\% on WebArena, reaching performance comparable to GPT-4o. WebWorld enables effective inference-time search, outperforming GPT-5 as a world model. Beyond web simulation, WebWorld exhibits cross-domain generalization to code, GUI, and game environments, providing a replicable recipe for world-model construction.
****

CocoRNA: Collective RNA Design with Cooperative Multi-agent Reinforcement Learning
Tianmeng Hu, Biao Luo, Ke Li
Designing RNA sequences that reliably fold into specific secondary structures is essential for understanding their biological functions but remains a challenging computational problem. We propose CocoRNA, a cooperative multi-agent reinforcement learning framework for RNA inverse design. CocoRNA simplifies the design task by decomposing it into smaller sub-problems, each solved collaboratively by multiple agents. This approach reduces the complexity of the problem and improves the exploration of design policies. During training, a centralized critic uses global structural information to guide the agents, enabling them to jointly optimize their design strategies. As a result, CocoRNA learns high-quality RNA design policies that generalize effectively to unseen structures without additional training. Experiments on the Rfam dataset demonstrate that CocoRNA substantially outperforms state-of-the-art methods in both success rate and design speed. Further experiments on other biological sequence design tasks highlight the effectiveness and broad potential of CocoRNA for complex design tasks.
****

Escaping the Likelihood Trap: Geometric Diversity Optimization for Long-Form Image Captioning
Qingmei Tang, Shuai Hao, Rong Fu, Zirui Mo, Xiang Liu, Jiaxuan Lu, Wenyu Wang
The utility of Vision-Language Models (VLMs) in reasoning and auditing tasks hinges on their ability to exhaustively describe visual scenes. However, current models exhibit a pathology we term the Likelihood Trap: standard alignment objectives, specifically MLE and KL-regularization, drive generation toward generic, high-probability templates, systematically suppressing fine-grained details. To overcome this, we introduce Geo-RL, a framework that shifts the objective from probabilistic likelihood to geometric coverage. Geo-RL reformulates caption generation as maximizing the volume of a parallelotope in semantic space. By leveraging Determinantal Point Processes (DPPs), we enforce orthogonality among sampled descriptions, ensuring that they span the image's full semantic support. Crucially, we derive a closed-form leave-one-out marginal reward, enabling stable policy optimization. Empirically, Geo-RL escapes the trap, achieving a significant improvement in semantic richness and detail coverage without compromising visual grounding.
****

Residual-Guided Multi-Resolution Refinement of Foundation Models: A Case Study in Drought Forecasting
Wentao Gao, Jiuyong Li, Lin Liu, Thuc Duy Le, Jixue Liu, Yanchang Zhao, Yun Chen
Regional climate prediction presents unique challenges for time series foundation models, which typically process temporal patterns through single-pass inference. Expert climatologists, in contrast, employ multi-scale temporal analysis and iterative refinement based on systematic error diagnosis. We present RGMR (Residual-Guided Multi-Resolution Refinement), an inference-time framework that adapts pre-trained foundation models to perform structured coarse-to-fine refinement for climate forecasting without updating backbone parameters. Applied to drought forecasting using the Standardized Precipitation Evapotranspiration Index (SPEI)

, RGMR is architecture-agnostic across the three TSFM backbones evaluated per si
te (TimesFM, TimeGPT, TabPFN) and consistently lowers test-set MSE on three Sout
h Australian sites and three additional regions outside South Australia. Applied
 to TimesFM, the wrapper reduces one-month-ahead SPEI MSE by up to 18.9\% across
 the three South Australian sites (mean reduction $\approx$18.7\%). Overall, RGM
R provides a practical route for deploying frozen TSFMs in regional climate fore
casting workflows.

AgentXRay: White-Boxing Agentic Systems via Workflow Reconstruction
Ruijie Shi, Houbin Zhang, Yuecheng Han, Yuheng Wang, Jingru Fan, Runde Yang, Yuf
an Dang, Huatao Li, Dewen Liu, Yuan Cheng, Chen Qian
Large Language Models have shown strong capabilities in complex problem solving,
 yet many agentic systems remain difficult to interpret and control due to opaqu
e internal workflows.
While some frameworks offer explicit architectures for collaboration, many deplo
yed agentic systems operate as black boxes to users.
We address this by introducing Agentic Workflow Reconstruction (AWR), a new task
 aiming to synthesize an explicit, interpretable stand-in workflow that approxim
ates a black-box system using only input--output access.
We propose AgentXRay, a search-based framework that formulates AWR as a combinat
orial optimization problem over discrete agent roles and tool invocations in a c
hain-structured workflow space.
Unlike model distillation, AgentXRay produces editable white-box workflows that
match target outputs under an observable, output-based proxy metric, without acc
essing model parameters.
To navigate the vast search space, AgentXRay employs Monte Carlo Tree Search enh
anced by a scoring-based Red-Black Pruning mechanism, which dynamically integrat
es proxy quality with search depth.
Experiments across diverse domains demonstrate that AgentXRay achieves higher pr
oxy similarity and reduces token consumption compared to unpruned search, enabli
ng deeper workflow exploration under fixed iteration budgets.

Global Plane Waves from Local Gaussians: Periodic Charge Densities in a Blink
Jonas Elsborg, Felix Aertebjerg, Luca Thiede, Alan Aspuru-Guzik, Tejs Vegge, Arg
hya Bhowmik
We introduce ELECTRAFI, a fast, end-to-end differentiable model for predicting p
eriodic charge densities in crystalline materials. ELECTRAFI constructs anisotro
pic Gaussians in real space and exploits their closed-form Fourier transforms to
 analytically evaluate plane-wave coefficients via the Poisson summation formula
. This formulation delegates non-local and periodic behavior to analytic transfo
rms, enabling reconstruction of the full periodic charge density with a single i
nverse FFT. By avoiding explicit real-space grid probing, periodic image summati
on, and spherical harmonic expansions, ELECTRAFI matches or exceeds state-of-the
-art accuracy across periodic benchmarks while being up to $633\times$ faster th
an the strongest competing method, reconstructing crystal charge densities in a
fraction of a second. When used to initialize DFT calculations, ELECTRAFI reduce
s total DFT compute cost by up to $\sim$20 \%, whereas slower charge density mod
els negate savings due to high inference times. Our results show that accuracy a
nd inference cost jointly determine end-to-end DFT speedups, and motivate our fo
cus on efficiency.

Bandit Social Leaning Dynamics with Exploration Episodes
Kiarash Banihashem, Natalie Collina, Aleksandrs Slivkins
We study a stylized social learning dynamics where self-interested agents collec
tively follow a simple multi-armed bandit protocol. Each agent controls an "epis
ode": a short sequence of consecutive decisions. Motivating applications include
 users repeatedly interacting with an AI, or repeatedly shopping at a marketplac
e. While agents are incentivized to explore within their respective episodes, we
 show that the aggregate exploration fails: e.g., its Bayesian regret grows line
arly over time. In fact, such failure is a (very) typical case, not just a worst

-case scenario. This conclusion persists even if an agent's per-episode utility is some fixed function of the per-round outcomes: e.g., $\min$ or $\max$, not just the sum. Thus, externally driven exploration is needed even when some amount of exploration happens organically.
****
Root Cause Analysis of Failures in Microservices via Bayesian Root Cause Discovery
Kenneth Lee, Zihan Zhou, Murat Kocaoglu
Modern cloud systems rely on architectures with many interconnected microservices, which enable scalability and flexibility but make troubleshooting failures difficult. Identifying the root cause requires navigating complex dependencies, often beyond the capacity of domain experts. Causal models offer a principled approach to root cause analysis (RCA), but prior methods are typically sample inefficient, as they assume access to the full causal graph or require large numbers of post-failure interventions. We introduce Bayesian Root Cause Discovery (BRCD), which leverages a partial causal structure (a CPDAG learned during the pre-failure period) and performs Bayesian inference without enumerating all DAGs from each interventional Markov equivalence class ($\mathcal{I}$-MEC) for each root cause candidate. Using a recent uniform DAG sampling framework (Wienöbst et al., 2023), BRCD provides the first statistical consistency guarantees for nonparametric RCA, with both identifiability and finite-sample posterior bounds under ε-vanishing approximation. Empirically, across synthetic benchmarks and three microservice systems (Online Boutique, Sockshop, Petshop), BRCD achieves state-of-the-art top-l accuracy while remaining effective in low-failure-sample regimes and scaling to large graphs.
****
Anchored Policy Optimization: Mitigating Exploration Collapse via Support-Constrained Rectification
Tianyi Wang, Long Li, Hongcan Guo, Yibiao Chen, Yixia Li, Yong Wang, Yun Chen, Guanhua Chen
Reinforcement Learning with Verifiable Rewards (RLVR) is increasingly viewed as a tree pruning mechanism. However, we identify a systemic pathology termed Recursive Space Contraction (RSC), an irreversible collapse driven by the combined dynamics of positive sharpening and negative squeezing, where the sampling probability of valid alternatives vanishes. While Kullback-Leibler (KL) regularization aims to mitigate this, it imposes a rigid Shape Matching constraint that forces the policy to mimic the reference model's full density, creating a gradient conflict with the sharpening required for correctness. We propose Anchored Policy Optimization (APO), shifting the paradigm from global Shape Matching to Support Coverage. By defining a Safe Manifold based on the reference model's high-confidence support, APO permits aggressive sharpening for efficiency while selectively invoking a restorative force during error correction to prevent collapse. We theoretically derive that APO serves as a gradient-aligned mechanism to maximize support coverage, enabling an Elastic Recovery that re-inflates valid branches. Empirical evaluations on mathematical benchmarks demonstrate that APO breaks the accuracy-diversity trade-off, significantly improving Pass@1 while restoring the Pass@K diversity typically lost by standard policy gradient methods.

Know More, Know Clearer: A Meta-Cognitive Framework for Knowledge Augmentation in Large Language Models
Hao Chen, Ye He, Yuchun Fan, Yukun Yan, Zhenghao Liu, Qingfu Zhu, Maosong Sun, Wanxiang Che
Knowledge augmentation has significantly enhanced the performance of Large Language Models (LLMs) in knowledge-intensive tasks. However, existing methods typically operate on the simplistic premise that model performance equates with internal knowledge, overlooking the knowledge-confidence gaps that lead to overconfident errors or uncertain truths. To bridge this gap, we propose a novel meta-cognitive framework for reliable knowledge augmentation via differentiated intervention and alignment. Our approach leverages internal cognitive signals to partition the knowledge space into mastered, confused, and missing regions, guiding targe

ted knowledge expansion. Furthermore, we introduce a cognitive consistency mecha nism to synchronize subjective certainty with objective accuracy, ensuring calib rated knowledge boundaries. Extensive experiments demonstrate the our framework consistently outperforms strong baselines, validating its rationality in not onl y enhancing knowledge capabilities but also fostering cognitive behaviors that b etter distinguish knowns from unknowns. All codes are available at https://githu b.com/AI9Stars/Know-More-Know-Clearer.

PMSPO: Progressive Matching and Semantic-Aware Policy Optimization for Camouflag ed Object Detection

Maosheng Su, Junlei Cao, Zhiyuan Wang, Shuo Wang, Ning Zhang, Jun Luo

Reinforcement learning-based Multimodal Large Language Models (MLLMs) provide ne w perspectives for visual grounding, yet face significant challenges in Camoufla ged Object Detection (COD) where objects blend seamlessly with backgrounds. This stems primarily from: difficulties in multi-object matching, the detrimental ef fects of low-quality samples, and erroneously localizing visual distractors with similar textures to true objects. We propose Progressive Matching and Semantic-aware Policy Optimization (PMSPO), a curriculum learning-based framework that em ploys Sinkhorn multi-object matching IoU reward during training for multi-object alignment, utilizes Positive Learning Gain Filtering (PLGF) to curate high-qual ity samples, and transforms deep visual features into semantic contrastive rewar d rules to calibrate target background semantics. Experiments on COD benchmarks demonstrate that PMSPO achieves state-of-the-art (SOTA) performance among reinfo rcement learning methods across all evaluation metrics.

****

Exploring Motif-based Heterogeneous Graph Learning for ReDoS Detection

Hong Huang, Chengyu Yao, Rongchen Li, Weihao Su, Chengyao Peng, Haiming Chen, Gu iyi He

Regular expressions (regexes) frequently exhibit super-linear worst-case behavio r in regex engines, exposing software to Regex Denial-of-Service (ReDoS) attacks . Detecting such vulnerabilities is challenging, especially for extended feature s such as lookarounds and backreferences: existing static approaches are efficie nt but often lack support for extended features, whereas dynamic and hybrid appr oaches reduce false positives by executing regex matching on real engines, but i ncur high runtime overhead. To address this trade-off, we propose ReDoS-MotifGNN (RMGNN), a motif-based graph learning framework for ReDoS detection that levera ges the low inference latency of graph neural networks (GNNs). RMGNN converts re gexes into Heterogeneous Regex Graphs (HRGs) and encodes three ReDoS-related mot ifs into HRGs to incorporate domain priors, while preserving the syntactic struc ture and extended features of the input regex. Furthermore, it applies heterogen eous propagation with kernel-guided motif learning to capture multi-scale semant ics, which are fused via residual cross-attention for robust prediction. Compreh ensive evaluation on four real-world datasets (over 317k regexes) demonstrates t hat RMGNN outperforms six state-of-the-art baselines in F1-score and achieves an average 244$\times$ speedup over the top F1-performing baseline.

Prototype Transformer: Towards Language Model Architectures Interpretable by Des ign

Yordan Yordanov, Matteo Forasassi, Bayar Menzat, Ruizhi Wang, Chang Qi, Markus K altenberger, Amine M'Charrak, Tommaso Salvatori, Thomas Lukasiewicz

While state-of-the-art language models (LMs) surpass the vast majority of humans in certain domains, their reasoning remains largely opaque, reducing trust and risking deception and hallucination. In this work, we introduce the Prototype Tr ansformer (ProtoT)—an autoregressive LM architecture that replaces the quadratic -cost self-attention in the transformer with a linear-cost module based on proto types (parameter vectors). In ProtoT, the prototypes create communication channe ls aggregating contextual information at different time scales. We show that thi s leads to the prototypes automatically capturing nameable concepts (e.g. “woman ”) during training, and it provides the potential to interpret the model’s reaso ning and do targeted edits of its behavior. Compared to baselines, ProtoT scales

well with model and data size, shows robustness to input perturbations, and performs well on text generation and downstream tasks (GLUE). These results suggest that ProtoT is a promising step toward autoregressive language models that are more interpretable by design.

Online Conformal Prediction via Universal Portfolio Algorithms

Tuo Liu, Edgar Dobriban, Francesco Orabona

Online conformal prediction (OCP) seeks prediction intervals that achieve long-run $1-\alpha$ coverage for arbitrary (possibly adversarial) data streams, while remaining as informative as possible. Existing OCP methods often require manual learning-rate tuning to work well, and may also require algorithm-specific analyses. Here, we develop a general regret-to-coverage theory for interval-valued OCP based on the $(1-\alpha)$-pinball loss. Our first contribution is to identify *linearized regret* as a key notion, showing that controlling it implies coverage bounds for any online algorithm. This relies on a black-box reduction that depends only on the Fenchel conjugate of an upper bound on the linearized regret. Building on this theory, we propose UP-OCP, a parameter-free method for OCP, via a reduction to a two-asset portfolio selection problem, leveraging universal portfolio algorithms. We show strong finite-time bounds on the miscoverage of UP-OCP, even for polynomially growing predictions. Extensive experiments support that UP-OCP delivers consistently better size/coverage trade-offs than prior online conformal baselines.

Rooted Absorbed Prefix Trajectory Balance with Submodular Replay for GFlowNet Training

Xi Wang, Wenbo Lu, Shenji Wan

Generative Flow Networks (GFlowNets) enable fine-tuning large language models to approximate reward-proportional posteriors, but they remain prone to mode collapse, manifesting as prefix collapse and length bias. We attribute this to two factors: (i) weak credit assignment to early prefixes, and (ii) biased replay that induces a shifted, non-representative training flow distribution. We propose Rooted absorbed prefix Trajectory Balance (RapTB), an objective that anchors subtrajectory supervision at the root and propagates terminal rewards to intermediate prefixes via absorbed suffix-based backups, providing dense prefix-level learning signals. To mitigate replay-induced distribution shift, we further introduce SubM, a submodular replay refresh strategy that promotes both high reward and diversity.

Empirically, on tasks such as molecule generation with LLM using SMILES strings, RapTB combined with SubM consistently improves optimization performance and molecular diversity while preserving high validity.

Singular Vectors of Attention Heads Align with Features

Gabriel Franco, Carson Loughridge, Mark Crovella

Identifying feature representations in language models is a central task in mechanistic interpretability. Several recent studies have made the observation that feature representations can be inferred in some cases from singular vectors of attention matrices. However, sound justification for this phenomenon is lacking. In this paper we address that question, asking: why and when do singular vectors align with features? First, we demonstrate that singular vectors robustly align with features in a model where features can be directly observed. We then show theoretically that such alignment is expected under a range of conditions. We close by asking how, operationally, alignment may be recognized in real models where feature representations are not directly observable. We identify *sparse attention decomposition* as a testable prediction of alignment, and show evidence that it emerges in real models in a manner consistent with predictions. Together these results suggest that alignment of singular vectors with features can be a sound and theoretically justified basis for feature identification in language models.

LLMInertia: Adaptive Counter-Inertial Reasoning to Improve Evidence Faithfulness

in Large Language Models
Xinxin You, Xien Liu, Chenwei Yan, Siqi Song, Chen Ning, Kaiyin Zhou, Shaohui Liu, Ji Wu
Large Language Models (LLMs) frequently generate output that contradicts explicit input evidence, limiting their reliability in real-world applications. We identify cognitive inertia in LLMs—a tendency to overly rely on co-occurrence associations learned during pretraining and to resist adaptation when conflicting input evidence appears—as a critical factor behind such hallucinations. We further empirically show that adherence to input evidence declines as co-occurrence associations are strengthened—driven by either higher data frequency or intensified training. Inspired by human counter-inertial thinking, we propose an adaptive counter-inertial reasoning framework that probes input-related cognitive inertia in the LLM and generates adaptive counter-inertial reminders, which are then injected into the prompt to promote evidence-based reasoning. Experiments on co-occurrence induction datasets show that LLMInertia reduces hallucination rates by up to 35\% and improves accuracy by up to 35.68\%. Extensive evaluations on four context-rich summarization and QA datasets, across three LLM backbones of varying scales, further validate its effectiveness and robustness. Our work provides new insight into the causes of input-unfaithful hallucinations in LLMs, contributing to the development of more reliable AI.

Principle-Evolvable Scientific Discovery via Uncertainty Minimization
Yingming Pu, Tao Lin, Hongyu Chen
Large Language Model (LLM)-based scientific agents have accelerated scientific discovery, yet they often suffer from significant inefficiencies due to adherence to fixed initial priors.
Existing approaches predominantly operate within a static hypothesis space, which restricts the discovery of novel phenomena, resulting in computational waste when baseline theories fail.
To address this, we propose shifting the focus from searching hypotheses to evolving the underlying scientific principles.
We present $\textbf{PiEvo}$, a principle-evolvable framework that treats scientific discovery as Bayesian optimization over an expanding principle space. By integrating Information-Directed Hypothesis Selection via Gaussian Process and an anomaly-driven augmentation mechanism, PiEvo enables agents to autonomously refine their theoretical worldview.
Evaluation across four benchmarks demonstrates that PiEvo (1) achieves an average solution quality of up to 90.81\%$\sim$93.15\%, representing a 29.7\%$\sim$31.1\% improvement over the state-of-the-art, (2) attains an 83.3\% speedup in convergence step via significantly reduced sample complexity by optimizing the compact principle space, and (3) maintains robust performance across diverse scientific domains and LLM backbones.
Code is publicly available at github.com/amair-lab/PiEvo.

SliceFine: The Universal Winning-Slice Hypothesis for Pretrained Networks
Md Kowsher, Ali O. Polat, Ehsan Mohammady Ardehaly, Mehrdad Salehi, Zia Ghiasi, Prasanth Murali, Chen Chen
This paper presents a theoretical framework that explains why fine-tuning small, randomly selected subnetworks (slices) within pre-trained models is sufficient for downstream adaptation. We establish that pretrained networks exhibit a universal winning slice property, arising from two phenomena: (1) spectral balance—the eigenspectra of different weight matrix slices are remarkably similar—and (2) high task energy—their backbone representations (pretrained weights) retain rich, task-relevant features. This leads to the Universal Winning Slice Hypothesis, which provides a theoretical foundation for parameter-efficient fine-tuning (PEFT) in large-scale models. Inspired by this, we propose SliceFine, a PEFT method that uses this inherent redundancy by updating only selected slices of the origi- nal weights—introducing zero new parameters, unlike adapter-based approaches. Empirically, SliceFine matches the performance of SOTA PEFT methods across various language and vision tasks, while significantly improving training speed, me

mory efficiency, and model compactness. Our work bridges theory and prac- tice, offering a theoretically grounded alternative to existing PEFT techniques.

Continual Learning of Domain-Invariant Representations
Pascal Janetzky, Tobias Schlagenhauf, Stefan Feuerriegel
Continual learning (CL) aims to train models sequentially over multiple domains without forgetting previously learned knowledge. However, existing CL methods optimize for in-domain performance and are therefore prone to learning spurious, domain-specific cues ("shortcut learning"), which limits generalization to unseen domains after deployment. In this paper, we address this limitation through *continual learning of domain-invariant representation*. We introduce a broad class of CL methods that sequentially learn representations capturing invariant structures across domains. Our methods are motivated by the observation that such invariant structures often preserve the underlying causal mechanisms, which can reduce the risk of overfitting to domain-specific cues and thus offer better out-of-domain generalization. Our proposed CL methods combine replay-based training with a tailored sequential invariance alignment to learn---and preserve---invariant structures over time. We evaluate our methods under a deployment-oriented protocol that measures performance on unseen target domains. Across six benchmark and real-world datasets spanning vision, medicine, manufacturing, and ecology, our methods consistently outperform existing CL baselines in terms of generalization to unseen target domains. As an ablation, we further show that naïve extensions of sequential training with existing domain-invariant representation learning (DIRL) methods provide only limited benefits. To the best of our knowledge, this is the first work to develop domain-invariant representation methods for CL.

MMPD-Bench: Bridging Multimodal Fission with Multi-Polarimetric Modalities Decomposition
Yi He, Zimo Zhao, Yiming Yang, Xiaoyuan Cheng, Chao He, Yukun Hu
Recovering multiple physical parameters from high-dimensional optical measurements remains challenging in computational optics. We present *MMPD-Bench*, a pioneering benchmark that reframes multi-polarimetric modalities decomposition from Mueller matrix observations as a *modality fission* problem under the multi-modal learning paradigm. By replacing iterative numerical inversion with deep surrogate models, MMPD-Bench provides data, standardized solutions and evaluations to address the multi-physics modalities generation challenge. We benchmark representative architectures to this problem, including state-space models, vision transformers, conditional diffusion models, and neural operators, under a multi-faceted evaluation protocol that jointly assesses perceptual fidelity, physical consistency, robustness, and computational efficiency. Our analysis reveals non-trivial trade-offs between accuracy and robustness in accelerated high-fidelity polarimetric decomposition, highlighting key limitations of existing surrogates. To support reproducible research, we open-source the full codebase, together with a large-scale dataset of 21,412 high-resolution Mueller matrix observations acquired through extensive polarimetric measurements. We invite the community to further advance the intersection of polarization optics and multimodal representation learning.
****
GAUSS: Graph-Assisted Uncertainty Quantification using Structure and Semantics for Long-Form Generation in LLMs
Karthik Somayaji NS, Yuxuan Yin, Peng Li
In critical domains like clinical reporting, legal analysis, and policy drafting, large language models (LLMs) are increasingly expected to produce extended, fact■rich narratives rather than isolated sentences. Reliable uncertainty quantification in such long■form outputs is crucial. Existing techniques either assign a single confidence score to an entire paragraph or evaluate factual consistency by comparing extracted atomic facts across multiple generations. Some recent approaches represent fact–paragraph relationships using bipartite entailment graphs and derive uncertainty from fact centrality. However, these methods ignore the explicit dependencies among facts within a paragraph and the structural and sema

ntic variation across multiple LLM outputs for the same prompt, missing a key so urce of uncertainty specific to long■form generation. We propose **GAUSS** (**G* *raph■**A**ssisted **U**ncertainty **Q**uantification using **S**tructure and ** S**emantics), a principled framework that models each generated paragraph as a s emantic graph of atomic facts and their relations. We posit that uncertainty ari ses from structural and semantic discrepancies among these graphs across differe nt samples. **GAUSS** quantifies uncertainty as the expected alignment cost betw een the semantic graph of an anchor paragraph and those of alternative generatio ns. By capturing both semantic content and structural coherence, **GAUSS** offer s a more interpretable and theoretically grounded measure of uncertainty than co arse, sentence■level scores.

PyVision-RL: Forging Open Agentic Vision Models via RL

Shitian Zhao, Shaoheng Lin, Ming Li, Haoquan Zhang, Wenshuo Peng, Kaipeng Zhang, Chen Wei

Reinforcement learning for agentic multimodal models often suffers from interact ion collapse, where models learn to reduce tool usage and multi-turn reasoning, limiting the benefits of agentic behavior. We introduce PyVision-RL, a reinforce ment learning framework for open-weight multimodal models that stabilizes traini ng and sustains interaction. Our approach combines an oversampling–filtering–ran king rollout strategy with an accumulative tool reward to prevent collapse and e ncourage multi-turn tool use. Using a unified training pipeline, we develop PyVi sion-Image and PyVision-Video for image and video understanding. For video reaso ning, PyVision-Video employs on-demand context construction, selectively samplin g task-relevant frames during reasoning to significantly reduce visual token usa ge. Experiments show strong performance and improved efficiency, demonstrating t hat sustained interaction and on-demand visual processing are critical for scala ble multimodal agents.

Generalizable and Actionable Parts Pose Estimation with Symmetry Annotation-Free Learning Strategy

wenxiao chen, Xueyu Yuan, Liu Liu, Di Wu, Dan Guo

Urgently needed generalizable robot object interaction and manipulation requires high-quality Cross-Category object perception. As a pioneer of this area, Gener alizable and Actionable Parts (GAParts) understanding has attracted increasing a ttention from relevant researchers. However, most recent works either have insuf ficient design regarding the symmetry issue or require rich symmetry annotation, which severely impedes precise GAPart pose estimation in data-lacking scenarios . In this paper, we propose SAFAG, a novel Symmetry Annotation-Free framework fo r Generalizable and Actionable Parts Pose Estimation. Specifically, we suggest a stepwise refinement two-stage framework for candidate-to-final quaternion regre ssion, and tackle the symmetry prediction as a probability distribution problem with self-supervised learning strategy. The experimental results demonstrate the superior performance and robustness of our SAFAG. We believe that our work has the enormous potential to be applied in many areas of embodied AI system.

HO-SFL: Hybrid-Order Split Federated Learning with Backprop-Free Clients and Dim ension-Free Aggregation

Qiyuan Chen, Xian Wu, Yi Wang, Xianhao Chen

Fine-tuning large models on edge devices is severely hindered by the memory-inte nsive backpropagation (BP) in standard frameworks like federated learning and sp lit learning. While substituting BP with zeroth-order optimization can significa ntly reduce memory footprints, it typically suffers from prohibitively degraded convergence speed. To resolve this dilemma, we propose *Hybrid-Order Split Feder ated Learning* (HO-SFL). By reformulating the split learning process within a La grangian framework, HO-SFL decouples the optimization landscape: The server perf orms precise first-order updates (i.e., BP), whereas clients conduct memory-effi cient zeroth-order optimization. This hybrid design not only eliminates the need for client-side BP but also enables dimension-free model aggregation, drastical ly lowering communication costs. Crucially, we provide a theoretical convergence

analysis, demonstrating that HO-SFL mitigates the dimension-dependent convergence slowdown of zeroth-order optimization, achieving a convergence rate comparable to first-order methods. Extensive experiments on tasks across vision and language modalities validate that HO-SFL achieves convergence speeds comparable to first-order baselines while significantly reducing communication costs and client memory footprints.

Low-Rank and Sparsity Are All You Need: Exploring Robust Hierarchical Latent Subspaces for Transferable Adversarial Attack

Shuangshuang Pu, Wen Yang, Min Li, Guodong Liu, Chris Ding, Di Ming

Adversarial examples pose serious threats to deep neural networks, exposing fundamental vulnerabilities in model robustness. However, most existing adversarial attacks directly manipulate dense and redundant feature representations, often leading to overfitting on surrogate models and poor black-box transferability. Recent SVD-based attack attempts to exploit low-rank feature subspaces, yet its reliance on single-layer optimization and single-gradient pathway neglects structural redundancy in feature representations and hierarchical heterogeneity across layers. To address these limitations, we propose LRS-Attack, a low-rank and sparse decomposition attack that explicitly models robust hierarchical subspaces in latent feature spaces. Specifically, the low-rank component captures dominant semantic directions, while the sparse component captures localized and discriminative patterns. To efficiently extract low-rank structure while preserving subspace fidelity, we develop a warm-started alternating low-rank approximation algorithm. Moreover, we introduce a hierarchical mixture of robust experts that leverages depth-dependent feature characteristics and guides gradient optimization toward more transferable adversarial directions. Extensive experiments on ImageNet show that LRS-Attack consistently improves black-box transferability over state-of-the-art methods across diverse CNN/ViT architectures and defense settings. Code is available at https://github.com/AdvML-Group/LRS-Attack.

Spectral Reach: Understanding Neural Scaling as Progress into the Spectral Tail

Konstantin Nikolaou, Jonas Scheunemann, Sven Krippendorf, Samuel Tovey, Christian Holm

Neural scaling laws describe predictable power-law relationships between model size, dataset size, compute, and performance. While these laws guide the development of modern foundation models, the mechanisms underpinning them remain poorly understood, in part due to the absence of scalable analysis tools. To close this gap, we introduce *spectral position*: a scalable measure of which eigenvalues of the empirical neural tangent kernel (eNTK) currently drive loss reduction. Applying this measure to scaling experiments, we find that spectral position decreases throughout training: learning shifts from dominant eigenmodes into the spectral tail. Larger models reach further into the tail than smaller models, revealing a size-dependent capacity we call *spectral reach*. This suggests why larger models achieve lower losses: they sustain learning on weak spectral signals inaccessible to smaller models. We further identify feature learning as a key enabler of spectral reach. It adaptively amplifies gradient magnitudes as learning advances, sustaining progress where frozen representations stall. This points to concrete interventions through architecture and optimizer design.

Flow for Future: Geometric SE(3)-Equivariant Flow Matching for 3D Trajectory Prediction

Junwei Wu, Yihang Liu, Ruixuan Yu, Jian Sun

Predicting 3D geometric trajectory requires capturing complex spatiotemporal dependencies while preserving physical symmetries. While flow matching offers a powerful generative paradigm, extending it to SE(3)-equivariant dynamics is challenging due to the inherent gap between deterministic history and stochastic evolving flows. To address this, we introduce GSE-Flow, an SE(3)-equivariant flow matching framework. We first propose a Coherent Sequence Encoding and Time-Modulated Embedding strategy that unifies historical and evolving streams, incorporating velocity and flow time via equivariant affine transformations to guide contin

uous evolution. We further design a Geometry-Feature Tensorization mechanism tha t projects node states into a tensor product space, enabling Context-Flow Fusion to guide trajectory evolution with historical context. GSE-Flow guarantees theo retical SE(3)-equivariance and achieves SOTA accuracy on MD17, MD22, and CMU MoC ap benchmarks for geometric trajectory prediction, while demonstrating generalit y by enhancing deterministic baselines. Code is available at https://github.com /aegine/GSE-Flow.

Reinforcing Real-world Service Agents: Balancing Utility and Cost in Task-orient ed Dialogue
Ning Gao, Wei Zhang, Yuqin Dai, Ling Shi, Ziyin Wang, Yujie Wang, Wei He, Jinpen g Wang, Chaozheng Wang
The rapid evolution of Large Language Models (LLMs) has accelerated the transiti on from conversational chatbots to general agents. However, effectively balancin g empathetic communication with budget-aware decision-making remains an open cha llenge. Since existing methods fail to capture these complex strategic trade-off s, we propose InteractCS-RL, a framework that reframes task-oriented dialogue as a multi-granularity reinforcement learning process. Specifically, we first esta blish a User-centric Interaction Framework to provide a high-fidelity training g ym, enabling agents to dynamically explore diverse strategies with persona-drive n users. Then, we introduce Cost-aware Multi-turn Policy Optimization (CMPO) wit h a hybrid advantage estimation strategy. By integrating generative process cred its and employing a PID-Lagrangian cost controller, CMPO effectively guides the policy to explore Pareto boundary between user reward and global cost constraint s. Extensive experiments on customized real business scenarios demonstrate that InteractCS-RL significantly outperform other baselines across three evaluation d imensions. Further evaluation on tool-agent-user interaction benchmarks verify I nteractCS-RL robustness across diverse domains. The source code and data are av ailable at https://github.com/NingGao-Ai/InteractCS-RL.

Local-Minima-Preserving Polynomial Relaxation of Ising Problems
Debraj Banerjee, Santanu Mahapatra, Kunal N. Chaudhury
The generalized Ising problem captures a broad spectrum of hard combinatorial pr oblems, including MAX-CUT, Number Partitioning (NPP), and Maximum Independent Se t. In this work, we consider the notion of one-flip local minima for this proble m. We construct a polynomial relaxation and prove the landscape equivalence theo rem: there exists a one-to-one correspondence between the local minima of the re laxation and the one-flip local minima of the original Ising problem. This guara ntee reduces the Ising problem to finding the local minima of a smooth function, allowing us to leverage scalable gradient-based optimizers such as ADAM. We dem onstrate that our method achieves strong performance across challenging benchmar ks, including spin-glass models, MAX-CUT, and NPP.
****
Learning Hamiltonian Flow Maps: Mean Flow Consistency for Large-Timestep Molecul ar Dynamics
Winfried Ripken, Michael Plainer, Gregor Lied, Thorben Frank, Oliver T. Unke, St efan Chmiela, Frank Noe, Klaus Robert Muller
Simulating the long-time evolution of Hamiltonian systems is limited by the smal l timesteps required for stable numerical integration. To overcome this constrai nt, we introduce a framework to learn *Hamiltonian Flow Maps* by predicting the *mean* phase-space evolution over a chosen time span Δt, enabling stable large-timestep updates far beyond the stability limits of classical integrators . To this end, we impose a *Mean Flow* consistency condition for time-averaged H amiltonian dynamics. Unlike prior approaches, this allows training on independen t phase-space samples without access to future states, avoiding expensive trajec tory generation. Validated across diverse Hamiltonian systems, our method in par ticular improves upon molecular dynamics simulations using machine-learned force fields (MLFF). Our models maintain comparable training and inference cost, but support significantly larger integration timesteps while trained directly on wid ely-available *trajectory-free* MLFF datasets.

AutoQRA: Joint Optimization of Mixed-Precision Quantization and Low-rank Adapters for Efficient LLM Fine-Tuning
Changhai Zhou, Shiyang Zhang, Yuhua Zhou, Qian Qiao, Jun Gao, Cheng Jin, KAIZHOU QIN, WEIZHONG ZHANG
Quantization followed by parameter-efficient fine-tuning has emerged as a promising paradigm for downstream adaptation under tight GPU memory constraints. However, this sequential pipeline fails to leverage the intricate interaction between quantization bit-width and LoRA rank. Specifically, a carefully optimized quantization allocation with low quantization error does not always translate to strong fine-tuning performance, and different bit-width and rank configurations can lead to significantly varying outcomes under the same memory budget. To address this limitation, we propose AutoQRA, a joint optimization framework that simultaneously optimizes the bit-width and LoRA rank configuration for each layer during the mixed quantized fine-tuning process. To tackle the challenges posed by the large discrete search space and the high evaluation cost associated with frequent fine-tuning iterations, AutoQRA decomposes the optimization process into two stages. First, it first conducts a global multi-fidelity evolutionary search, where the initial population is warm-started by injecting layer-wise importance priors.
This stage employs specific operators and a performance model to efficiently screen candidate configurations. Second, trust-region Bayesian optimization is applied to locally refine promising regions of the search space and identify optimal configurations under the given memory budget. This approach enables active compensation for quantization noise in specific layers during training. Experiments show that AutoQRA achieves performance close to full-precision fine-tuning with a memory footprint comparable to uniform 4-bit methods.
****
Unison: Benchmarking Unified Multimodal Models via Synergistic Understanding and Generation
Jinyu Liu, Xincheng Shuai, Henghui Ding, Yu-Gang Jiang
Unified multimodal models capable of both understanding and generation have achieved remarkable strides. However, despite their unified designs, existing evaluations typically assess understanding and generation capabilities in isolation, overlooking the synergy between comprehension and generation. To bridge this gap, we introduce **Unison**, a comprehensive benchmark comprising 2,169 high-quality unified task samples, designed to evaluate joint understanding and generation in unified multimodal models. Unison offers three key strengths: **1) Comprehensive Dimensions**: Unison encompasses internal consistency, understanding-guided generation, generation-guided understanding, and mutual enhancement to enable holistic evaluation. **2) Diagnostic Evaluation**: it provides both unified and decoupled tracks for understanding and generation, allowing fine-grained attribution of failure modes and quantitative analysis of the gains from unified modeling. **3) Human Alignment**: we also train Unison-Judge, an evaluation model well aligned with human judgments to achieve reliable assessment. Based on systematic evaluations of state-of-the-art models on Unison, we uncover critical limitations in current unified multimodal systems and highlight promising directions for future research. Unison will be publicly available at https://github.com/FudanCVL/Unison.
****
Control Consistency Losses for Diffusion Bridges
Samuel Howard, Nikolas Nüsken, Jakiw Pidstrigach
Simulating the conditioned dynamics of diffusion processes, given their initial and terminal states, is an important but challenging problem in the sciences. The difficulty is particularly pronounced for rare events, for which the unconditioned dynamics rarely reach the terminal state. In this work, we propose a novel approach for learning diffusion bridges based on a self-consistency property of the optimal control. The resulting algorithm learns the conditioned dynamics in an iterative online manner, and exhibits strong performance in a range of empirical settings without requiring differentiation through simulated trajectories. B

eyond the diffusion bridge setting, we draw connections between our self-consist ency framework and recent advances in the wider stochastic optimal control liter ature.

SAC-Opt: Semantic Anchors for Iterative Correction in Optimization Modeling
Yansen Zhang, Qingcan Kang, Yujie chen, Yufei Wang, Xiongwei Han, Tao Zhong, Min gxuan Yuan, Chen Ma
Large language models (LLMs) have opened new paradigms in optimization modeling by enabling the generation of executable solver code from natural language descr iptions. Despite this promise, existing approaches typically remain solver-drive n: they rely on single-pass forward generation and apply limited post-hoc fixes based on solver error messages, leaving undetected semantic errors that silently produce syntactically correct but logically flawed models. To address this chal lenge, we propose SAC-Opt, a backward-guided correction framework that grounds o ptimization modeling in problem semantics rather than solver feedback. At each s tep, SAC-Opt aligns the original semantic anchors with those reconstructed from the generated code and selectively corrects only the mismatched components, driv ing convergence toward a semantically faithful model. This anchor-driven correct ion enables fine-grained refinement of constraint and objective logic, enhancing both fidelity and robustness without requiring additional training or supervisi on. Empirical results on seven public datasets demonstrate that SAC-Opt improves average modeling accuracy by 7.7%, with gains of up to 21.9% on the ComplexLP d ataset. These findings highlight the importance of semantic-anchored correction in LLM-based optimization workflows to ensure faithful translation from problem intent to solver-executable code.

Reinforcement Learning with Pairwise Preferences in Long-Term Decision Problems
Jonathan Colaço Carr, Prakash Panangaden, Doina Precup, Benjamin Van Roy
Reinforcement-learning problems typically define the goal as maximizing the expe cted value of a scalar reward function. But, pairwise preferences are often easi er to specify than scalar rewards, and they express certain goals that scalar re wards cannot. Methods for reinforcement learning with pairwise preferences have thus received growing interest. Unfortunately, these methods are inefficient in problems with long time horizons, and they lack guarantees on the performance of Markov policies relative to history-dependent policies, which bridge the theory and practice of reinforcement learning. We therefore propose the *Markov decisi on contest* as a new problem model for reinforcement learning with pairwise pref erences. We prove that stationary Markov policies are optimal among all history- dependent policies, that solving a Markov decision contest exactly is in P, and that a simple iterative algorithm converges to an optimal policy at a sublinear rate. Lastly, in a set of high-dimensional decision problems with long time hori zons, we show that our approximate algorithm is significantly more learning-effi cient than prior work.

Interpretable Embeddings with Sparse Autoencoders: A Data Analysis Toolkit
Nicholas Jiang, Xiaoqing Sun, Lisa Dunlap, Lewis Smith, Neel Nanda
Analyzing large-scale text corpora is a core challenge in machine learning, cruc ial for tasks like identifying undesirable model behaviors. Current methods ofte n rely on costly LLM-based techniques (e.g. annotating dataset differences) or d ense embedding models (e.g. for clustering), which lack control over the propert ies of interest. We propose using sparse autoencoders (SAEs) to create *SAE embe ddings*: representations whose dimensions map to interpretable concepts. Through four data analysis tasks, we show that SAE embeddings are more cost-effective a nd reliable than LLMs and offer the controllability that dense embeddings lack. Using the large hypothesis space of SAEs, we can uncover insights such as (1) se mantic differences between datasets and (2) unexpected concept correlations in d ocuments. For instance, by comparing model responses, we find that Grok-4 clarif ies ambiguities more often than nine other frontier models. Relative to LLMs, SA E embeddings uncover bigger differences at 2-8x lower cost and identify biases m ore reliably. Additionally, SAE embeddings are controllable: by filtering concep

ts, we can (3) cluster documents along axes of interest and (4) outperform dense embeddings on property-based retrieval. Using SAE embeddings, we study model behavior with two case studies: investigating how OpenAI model behavior has changed over time and finding "trigger" phrases learned by Tulu-3 (Lambert et al., 2024) from its training data. These results position SAEs as a versatile tool for unstructured data analysis and highlight the neglected importance of interpreting models through their *data*.

GHOST: Geometry-Guided Hallucination of Opaque Surface Textures
Langxu Zhao, Zuan Gu, Tianhan Gao
Transparent objects pose a fundamental challenge for depth estimation and 3D reconstruction due to their violation of Lambertian assumptions, leading to severe geometry degradation in downstream tasks. To address this, we propose a novel geometry-guided preprocessing framework GHOST that leverages visual foundation models to transform transparent regions into opaque, structurally consistent representations without requiring downstream model retraining. Specifically, our pipeline utilizes (1) TransDINO and (2) TransDecomp to disentangle masks and transparency physical properties, while (3) DAF-Net recovers surface normal priors to encode geometric curvature. Subsequently, (4) GeoSemTransNet integrates these multi-modal cues to synthesize a texture-rich opaque RGB image that preserves the transparent object's 3D structure. Extensive experiments demonstrate that our method significantly enhances the accuracy of state-of-the-art depth estimation and reconstruction models on transparent objects by restoring essential photometric cues.

Infinite-Precision Autoregressive Modeling for Vector Graphics and Layouts
Yeonsang Shin, Insoo Kim, Bongkeun Kim, Keonwoo Bae, Bohyung Han
Transformer-based autoregressive models excel in data generation but are inherently constrained by their reliance on discretized tokens, which limits their ability to represent continuous values with high precision. We analyze the scalability limitations of existing discretization-based approaches for generating hybrid discrete-continuous sequences, particularly in high-precision domains such as logos, layouts, and semiconductor circuit designs, where precision loss potentially leads to visual artifacts, aesthetic degradation, and even functional failure. To address the challenge, we propose a novel unified framework that jointly models discrete and continuous values for variable-length sequences. Our approach employs a hybrid approach that combines categorical prediction for discrete values with diffusion-based modeling for continuous values, incorporating two key technical components: an end-of-sequence (EOS) logit adjustment mechanism that uses an MLP to dynamically adjust EOS token logits based on sequence context, and a length regularization term integrated into the loss function. Additionally, we present ContLayNet, a large-scale benchmark comprising 334K high-precision semiconductor layout samples with specialized evaluation metrics that capture functional correctness, where precision errors significantly impact performance. Experiments on semiconductor layouts (ContLayNet), graphic layouts, and SVGs demonstrate that our approach achieves higher-fidelity hybrid vector representations than discretization-based and fixed-schema baselines, while scaling to high-precision generation across multiple domains.
****

Epistemic Uncertainty Quantification for Pre-trained VLMs via Riemannian Flow Matching
Li Ju, Mayank Nautiyal, Andreas Hellander, Ekta Vats, Prashant Singh
Vision-Language Models (VLMs) are typically deterministic in nature and lack intrinsic mechanisms to quantify epistemic uncertainty, which reflects the model’s lack of knowledge or ignorance of its own representations. We theoretically motivate negative log-density of an embedding as a proxy for the epistemic uncertainty, where low-density regions signify model ignorance. The proposed method REPVLM computes the probability density on the hyperspherical manifold of the VLM embeddings using Riemannian Flow Matching. We empirically demonstrate that REPVLM achieves near-perfect correlation between uncertainty and prediction error, signi

ficantly outperforming existing baselines. Beyond classification, we also demons
trate that the model also provides a scalable metric for out-of-distribution det
ection and automated data curation.

D^{2}O: A Dual Debiasing Operator for Training-Free Test-Time Adaptation of Visi
on–Language Models

Yihong Luo, Wenwu He, Dong Liang, Yihang Zhou, Zhuo-Xu Cui

Training-free test-time adaptation (TTA) for vision-language models (VLMs) can i
mprove zero-shot classification under mild shifts, but often degrades under seve
re style/environment variation. We identify two shared failure modes in training
-free pipelines: (i) retrieval confounding, where feature similarity is dominate
d by nuisance/style variation and corrupts retrieval evidence; and (ii)
environment-biased priors, where VLM logits exhibit environment-dependent center
ed shifts that distort gating and prior-like terms. Therefore, we propose D^{2}O
, a training-free debiasing operator
that outputs three inference-time objects:
a retrieval-oriented content feature for semantic matching, a style-aware routin
g coordinate for bias tracking, and debiased logits for corrected priors. D^{2}O
 composes plug-and-play with retrieval-based and closed-form Gaussian adapters i
n online and transductive settings. We further provide operator-to-decision guar
antees: finite-difference covariance recovers a nuisance-sensitive subspace, rou
ting-based EMA controls centered-logit bias estimates, and these errors yield bo
unded posterior log-odds perturbations, leading to a margin-based condition for
label invariance. Extensive experiments show that D^{2}O achieves
its clearest gains under style/environment-dominant shifts,
with broader gains elsewhere. Code is available at \url{https://github.com/MAiTL
-Group/D2O}.

ViSurf: Visual Supervised-and-Reinforcement Fine-Tuning for Large Vision-and-Lan
guage Models

Yuqi Liu, Liangyu Chen, Jiazhen Liu, Mingkang Zhu, Zhisheng Zhong, Bei Yu, Jiaya
 Jia

Post-training Large Vision-and-Language Models (LVLMs) typically involves Superv
ised Fine-Tuning (SFT) for knowledge injection or Reinforcement Learning with Ve
rifiable Rewards (RLVR) for performance enhancement. However, SFT often leads to
 sub-optimal performance, while RLVR remains constrained by the model's internal
 knowledge base. While a sequential SFT $\rightarrow$ RLVR pipeline can be used,
 it introduces significant computational overhead and suffers from catastrophic
forgetting. To address these limitations, we propose ViSurf (\textbf{Vi}sual \te
xtbf{Su}pervised-and-\textbf{R}einforcement \textbf{F}ine-Tuning), a unified, si
ngle-stage paradigm that integrates the strengths of both SFT and RLVR. By analy
zing their training objectives, we establish a unified framework that injects gr
ound-truth labels directly into RLVR rollouts, facilitating simultaneous externa
l supervision and internal reinforcement. Furthermore, we introduce three novel
reward control strategies to ensure training stability and optimization. Extensi
ve experiments demonstrate that ViSurf consistently outperforms standalone SFT,
RLVR, and the traditional two-stage pipeline across diverse benchmarks. In-depth
 analysis corroborates these findings, validating the derivation and design prin
ciples of ViSurf.

CorrSteer: Generation-Time LLM Steering via Correlated Sparse Autoencoder Featur
es

Seonglae Cho, Zekun Wu, Adriano Koshiyama

Sparse Autoencoders (SAEs) decompose LLM activations into interpretable features
, yet existing SAE-based steering methods require contrastive datasets or large
activation stores. We introduce CorrSteer, which selects steering features by co
rrelating task outcomes with SAE activations computed during generation, then va
lidates these selections through intervention. This two-stage approach treats co
rrelation as a selection heuristic and intervention as the causal test: features
 that both correlate with success and improve performance when amplified are ret

ained. Coefficients derive from mean activations on correct samples, yielding a fully automated pipeline without task-specific tuning. On Gemma-2 2B and LLaMA-3.1 8B, CorrSteer achieves +3.3% on MMLU (4k samples) and +27.1% on HarmBench (108 samples), with lower side-effect ratios than fine-tuning despite comparable accuracy. Selected features cluster into interpretable categories: structured-output features for multiple-choice tasks, refusal features for safety, and domain-specific semantics for specialized benchmarks. The method scales to 10^5 SAE features (16K per layer × 26 layers for Gemma-2 2B; 32K × 32 for LLaMA-3.1 8B) via streaming correlation ($O(1)$ in dataset size), requiring no backward passes or activation storage.

Unlearning Isn't Deletion: Investigating Reversibility of Machine Unlearning in LLMs

Xiaoyu Xu, Xiang Yue, Yang Liu, Qingqing Ye, Huadi Zheng, Peizhao Hu, Minxin Du, Haibo Hu

Unlearning in large language models (LLMs) aims to remove specified data, but its efficacy is typically assessed with task-level metrics like accuracy and perplexity.
We show that these metrics can be misleading, as models can appear to forget while their original behavior is easily restored through minimal fine-tuning.
This \emph{reversibility} suggests that information is merely suppressed, not genuinely erased. To address this critical evaluation gap, we introduce a \emph{representation-level analysis framework}.
Our toolkit comprises PCA similarity and shift, centered kernel alignment (CKA), and Fisher information, complemented by a summary metric, the mean PCA distance, to measure representational drift.
Applying this framework across multiple unlearning methods, data domains, and LLMs, we identify four distinct forgetting regimes based on their \emph{reversibility} and \emph{catastrophicity}.
We compare recovery strategies and show that relearning efficiency relies on the data source. We also find that irreversible, non-catastrophic forgetting is exceptionally challenging. By probing unlearning limits, we identify a case of seemingly irreversible, targeted forgetting,
offering insights for more robust erasure algorithms. Overall, our findings expose a gap in
current evaluation and establish a representation-level foundation for trustworthy unlearning.

Rethinking GNNs and Missing Features: Challenges, Evaluation and a Robust Solution

Francesco Ferrini, Veronica Lachi, Antonio Longa, Bruno Lepri, Akiyoshi Matono, Andrea Passerini, Xin Liu, Manfred Jaeger

Handling missing node features is a key challenge for deploying Graph Neural Networks (GNNs) in real-world domains such as healthcare and sensor networks. Existing studies mostly address relatively benign scenarios, namely benchmark datasets with (a) high-dimensional but sparse node features and (b) incomplete data generated under Missing Completely At Random (MCAR) mechanisms. For (a), we theoretically prove that high sparsity substantially limits the information loss caused by missingness, making all models appear robust and preventing a meaningful comparison of their performance. To overcome this limitation, we introduce one synthetic and three real-world datasets with dense, semantically meaningful features. For (b), we move beyond MCAR and design evaluation protocols with more realistic missingness mechanisms. Moreover, we provide a theoretical background to state explicit assumptions on the missingness process and analyze their implications for different methods. Building on this analysis, we show that a simple baseline adapted to the graph domain is competitive with respect to specialized architectures across diverse datasets and missingness regimes.

MultiPriv: Benchmarking Individual-Level Privacy Reasoning in Vision-Language Models

Xiongtao Sun, HUI LI, Jiaming Zhang, Yujie Yang, Kaili Liu, Ruxin Feng, Wen Jun Tan, Wei Yang Bryan Lim

Modern Vision-Language Models (VLMs) pose significant individual-level privacy risks by linking fragmented multimodal data to identifiable individuals through hierarchical chain-of-thought reasoning. However, existing privacy benchmarks remain structurally insufficient for this threat, as they primarily evaluate privacy perception while failing to address the more critical risk of privacy reasoning: a VLM's ability to infer and link distributed information to construct individual profiles. To address this gap, we propose MultiPriv, the first benchmark designed to systematically evaluate individual-level privacy reasoning in VLMs. We introduce the Privacy Perception and Reasoning (PPR) framework and construct a bilingual multimodal dataset with synthetic individual profiles, where identifiers, such as faces and names, are linked to sensitive attributes. This design enables nine challenging tasks spanning attribute detection, cross-image re-identification, and chained inference. We conduct a large-scale evaluation of over 50 open-source and commercial VLMs. In our controlled benchmark, 60\% of widely used VLMs can perform individual-level privacy reasoning with up to 80\% accuracy, suggesting a significant potential threat to personal privacy. The benchmark is available at https://github.com/CyberChangAn/MultiPriv-PII.

Semi-Supervised Gaze Estimation via Disentangled Subspace Contrastive Learning

Qida Tan, Hongyu Yang, Wenchao Du

Appearance-based gaze estimation always suffers from poor generalization due to limited annotated samples and insufficient dataset diversity. Leading approaches adopt weakly supervised learning to generate large-scale pseudo-labeled data from unconstrained real-world scenarios, aiming to mitigate the domain shifts. In this work, we devise a simple yet effective semi-supervised learning architecture that leverages unlabeled data to enhance domain generalization, thereby reducing reliance on labor-intensive manual annotations. Our key insight is to impose Jacobian regularization to disentangle feature representations into discriminative subspaces dedicated to specific gaze components, such as pitch and yaw angles. We further exploit the intrinsic ordinal ranking within each subspace for contrastive learning, enabling the model to learn robust gaze representations from a small set of labeled samples and an abundance of unlabeled ones. This ultimately yields our Disentangled Subspace Contrastive Learning (DSCL) framework. Extensive experiments on multiple benchmarks verify that the proposed DSCL is plug-and-play, achieving competitive performance using only 20\%, 10\%, and even 5\% of the annotated data under both in-domain and cross-domain evaluation settings. The public code is available at \href{https://github.com/da60266/DSCL}{https://github.com/da60266/DSCL}.

Black-Box Detection of LLM-Generated Text Using Generalized Jensen Shannon Divergence

Shuangyi Chen, Ashish J Khisti

We study black-box detection of machine-generated text under practical constraints: the scoring model (proxy LM) may mismatch the unknown source model, and per-input contrastive generation is costly. We propose SurpMark, a reference-based detector that summarizes a passage by the dynamics of its token surprisals. SurpMark discretizes surprisals into interpretable states, estimates a state-transition matrix for the test text, and scores it via a generalized Jensen–Shannon (GJS) gap between the test transitions and two fixed references (human vs. machine) built once from existing corpora. Theoretically, we derive design guidance for how the discretization bins should scale with data and provide a principled justification for our test statistic. Empirically, across multiple datasets, source models, and scenarios, SurpMark consistently matches or surpasses baselines, demonstrating strong robustness across domains and generators; our experiments on hyperparameter sensitivity exhibit trends that our theoretical results help to explain.

Efficient Test-time Inference for Generative Planning Models with OCL Search

Robert Gieselmann, Mihai Samson, Federico Pecora, Jeremy L Wyatt
Generative models have emerged as a powerful paradigm for AI planning, yet their performance remains constrained by the training data distribution. One approach is to improve generated solutions during inference by scaling test-time compute. A more efficient alternative is to optimize the inference process itself. In this paper, we show that a modified version of a classical Open-Closed List (OCL) search provides just such an efficient inference procedure. Our algorithm synergizes two learned components: a generative model that performs fast rollouts from intermediate states and a heuristic model that prioritizes among candidate reasoning paths. Key contributions include novel exploration control mechanisms and integration of learned models within the OCL framework. Across multiple combinatorial planning domains, our approach outperforms both neurosymbolic search baselines and classical solvers in computational efficiency and solution quality.

Adversarially Robust Approximate Furthest Neighbor
Kiarash Banihashem, Jeff Giliberti, Prashant Gokhale, Samira Goudarzi, MohammadTaghi Hajiaghayi, Yuhao Liu, Morteza Monemizadeh, Sandeep Silwal
We work in the adaptive query model, where
one is given a point set $P \subset \mathbb{R}^d$ and seeks to construct a
data structure that can answer correctly and efficiently a sequence of adaptive queries.
In this model, an adversary observes the answers returned by the data structure to previous queries $q_1, \ldots, q_{i-1}$ and, based on this information, chooses
the next query point q_i.
This setting captures strong forms of adaptivity that naturally arise in modern machine learning pipelines, and rules out many
classical randomized techniques that assume oblivious queries.
Our focus is the problem of furthest neighbor search in this adaptive
setting, a fundamental problem in several learning tasks,
including diversity maximization, outlier and anomaly detection, adversarial example generation, and more. We present the first adversarially robust data structure for c-approximate furthest
neighbor queries that achieves query time $\tilde{O}(\min(d n^{1/c^2}, n^{2/c^2} + d))$. This matches the n dependency in the query time of the seminal result by Indyk [SODA'03] for c-approximate furthest neighbor in the oblivious setting, and improves upon the $\tilde{O}(n + d)$ query time achieved via the adaptive distance estimation framework of Cherapanamjeri and Nelson [NeurIPS'20] for a wide range of natural parameters. To complement this result, we present an adversarial attack against oblivious approximate furthest neighbor algorithms. Specifically, we show that the data structure from the algorithm by Indyk fails to maintain its guarantees against adaptive queries.
****
Seeking Commonality, Preserving Specificity: A Spectral-Aware Hierarchical Framework for Cross-City Road Representation Learning
Jingtian Ma, Jingyuan Wang, Leong Hou U
Learning unified road representations across diverse cities is a pivotal challenge in urban computing. However, existing approaches predominantly focus on single-city modeling, failing to handle the distribution shifts caused by heterogeneous urban layouts. We identify *spectral misalignment*, manifested as the significant divergence of spectral distributions across different cities, as the primary barrier preventing standard Graph Neural Networks from capturing universal patterns. To bridge this gap, we propose **CoSpec**, a framework that disentangles road networks into shareable low-frequency commonalities and city-specific high-frequency specificities. CoSpec employs a hierarchical dual-path architecture where the low-frequency path aligns global functional semantics via adaptive prototypes, while the high-frequency path modulates local geometric residuals to fit specific urban textures. Theoretical analysis shows CoSpec bounds the Wasserstein distance between city distributions, and extensive experiments demonstrate its superior generalization over state-of-the-art baselines.

****
Balancing Fidelity and Diversity in Diffusion Models via Symmetric Attention Decomposition: Hopfield Perspective
Hyunmin Cho, Woo Kyoung Han, Kyong Hwan Jin
We characterize the pre-softmax attention matrix $\mathbf{QK^\top}$ in transformers as an associative memory matrix encoding pairwise associations between input features. By decomposing this matrix into its symmetric and skew-symmetric parts, we interpret the symmetric component as governing the structure of the _energy landscape_, and the skew-symmetric component as driving _circulation_ on that landscape. Leveraging the energy formulation induced by the symmetric component, we derive Hopfield-style stability measures that quantify the stability of retrieved features. We observe meaningful correlations between Hopfield-style stability measures and the fidelity--diversity trade-offs in generation. Finally, we propose a controllable knob to modulate this trade-off by modifying the circulation of the underlying dynamics. Code is available at our Project Page (https://hyeon-cho.github.io/Balancing/).
****
MetaStreet: Semi-Supervised Multimodal Learning for Street-Level Socioeconomic Prediction
Meng Chen, Junjie Yang, Zechen Li, Kai Zhao, Hongjun Dai, Weiming Huang
Predicting street-level socioeconomic indicators from street view imagery is fundamental to urban planning. Existing methods typically extract visual features via pretrained encoders and propagate information through graph-based learning, but they fail to fully exploit the structured, task-relevant, and label-efficient learning signals inherent in urban scenes. We propose MetaStreet, a semi-supervised multimodal framework with three components: (1) a semantic-spatial visual encoder that jointly models object co-occurrence and spatial adjacency at the semantic category level, (2) a task-aware textual encoder that steers LLMs toward prediction-relevant features via task-specific prompts, and (3) a geography-aware graph contrastive learning module that leverages spatial autocorrelation to extend contrastive supervision to unlabeled streets, enabling them to actively participate in representation learning. Experiments on two cities across three socioeconomic prediction tasks demonstrate that MetaStreet consistently outperforms state-of-the-art methods.
****
EpiCache: Episodic KV Cache Management for Long-Term Conversation on Resource-Constrained Environments
Minsoo Kim, Arnav Kundu, Han-Byul Kim, Richa Dixit, Minsik Cho
Modern large language models (LLMs) extend context lengths to millions of tokens, enabling coherent, personalized responses grounded in long conversational history. However, the Key-Value (KV) cache grows linearly with the extended dialogue history, causing the model’s memory footprint to quickly exceed device limits. While recent KV cache compression methods attempt to reduce memory usage, most apply cache eviction after processing the entire context, incurring unbounded peak memory usage. Additionally, query-dependent eviction narrows the cache semantics to a single query, leading to failure cases in multi-turn conversations. In this paper, we introduce EpiCache, a training-free KV cache management framework for long conversational question answering (LongConvQA) under fixed memory budgets. EpiCache bounds cache growth through block-wise prefill and preserves topic-relevant context via episodic KV compression, which clusters conversation history into coherent episodes and performs episode-specific KV cache eviction. Across three LongConvQA benchmarks (LongMemEval, Realtalk, and LoCoMo), EpiCache improves accuracy by up to 30\%, achieves near-full-cache accuracy under 4–$6\times$ compression, and reduces latency and peak memory by up to $2.4\times$ and $3.7\times$, respectively.

Universal Redundancies in Time Series Foundation Models
Anthony Bao, Venkata Hasith Vattikuti, Jeffrey B. Lai, William Gilpin
Time Series Foundation Models (TSFMs) leverage extensive pretraining to accurately predict unseen time series during inference, without the need for task-specif

ic fine-tuning. Through large-scale evaluations of standard benchmarks, we find that leading transformer-based TSFMs exhibit redundant components in their intermediate layers. We introduce a set of tools for mechanistic interpretability of TSFMs, including ablations of specific components and direct logit attribution on the residual stream. Our findings are consistent across several leading TSFMs with diverse architectures, and across a diverse set of real-world and synthetic time-series datasets. We discover that all models in our study are robust to ablations of entire layers. Furthermore, we develop a theoretical framework framing transformers as kernel regressors, motivating a purely intrinsic strategy for ablating heads based on the stable rank of the per-head projection matrices. Using this approach, we uncover the specific heads responsible for degenerate phenomena widely observed in TSFMs, such as parroting of motifs from the context and seasonality bias. Our study sheds light on the universal properties of this emerging class of architectures for continuous-time sequence modeling.

A Critical Look at Targeted Instruction Selection: Disentangling What Matters (and What Doesn’t)

Nihal V. Nayak, Paula Rodriguez-Diaz, Neha Hulkund, Sara Beery, David Alvarez-Melis

Instruction fine-tuning of large language models (LLMs) often involves selecting a subset of instruction training data from a large candidate pool, using a small query set from the target task. Despite growing interest, the literature on targeted instruction selection remains fragmented and opaque: methods vary widely in selection budgets, often omit zero-shot baselines, and frequently entangle the contributions of key components. As a result, practitioners lack actionable guidance on selecting instructions for their target tasks. In this work, we aim to bring clarity to this landscape by disentangling and systematically analyzing the two core ingredients: data representation and selection algorithms. Our framework enables controlled comparisons across models, tasks, and budgets. We find that only gradient-based data representations choose subsets whose similarity to the query consistently predicts performance across datasets,models, and candidate pools. While no single method dominates, gradient-based representations paired with greedy round-robin selection often perform best on average at low budgets, but these gains diminish at larger budgets. Finally, we unify several existing selection algorithms as forms of approximate distance minimization between the selected subset and the query set, and support this view with new generalization bounds. More broadly, our findings provide critical insights and a foundation for more principled data selection in LLM fine-tuning. The code is available at https://github.com/dcml-lab/targeted-instruction-selection.

Practical and Scalable Hamiltonian Monte Carlo Without the Metropolis Test

Jakob Robnik, Reuben Cohn-Gordon, Uros Seljak

Hamiltonian Monte Carlo and underdamped Langevin Monte Carlo are state-of-the-art methods for taking samples from high-dimensional distributions with a differentiable density function. To generate samples, they numerically integrate Hamiltonian or Langevin dynamics. This numerical integration introduces an asymptotic bias in Monte Carlo estimators of expectation values, which can be eliminated by adjusting the dynamics with a Metropolis-Hastings (MH) proposal step. Alternatively, one can trade bias for variance by avoiding MH, and select an integration step size that ensures sufficiently small asymptotic bias, relative to the variance inherent in a finite set of samples. Such \emph{unadjusted} methods often significantly outperform their adjusted counterparts in high-dimensional problems where sampling would otherwise be prohibitively expensive, yet are rarely used in statistical applications due to the absence of an automated way of choosing a step size. We propose just such an automatic tuning scheme that takes a user-provided asymptotic bias tolerance and selects a step size that ensures it. The key to the method is a relationship we establish between the energy change during integration and the asymptotic bias. We show that this procedure rigorously bounds the asymptotic bias for Gaussian target distributions. We then numerically show that the procedure works beyond Gaussians. To demonstrate the practicality of t

he proposed scheme, we provide a comprehensive comparison of adjusted and unadju
sted samplers on Bayesian inference problems and on a statistical physics model
in more than one million parameters. With our tuning scheme, the unadjusted meth
ods achieve close to optimal performance, significantly and consistently outperf
orming their adjusted counterparts.

You Don’t Need All That Attention: Surgical Memorization Mitigation in Text-to-I
mage Diffusion Models
Kairan Zhao, Eleni Triantafillou, Peter Triantafillou
Generative models have been shown to "memorize" certain training data, leading t
o
verbatim or near-verbatim
generating images, which may cause privacy concerns or copyright infringement. W
e introduce Guidance Using Attractive-Repulsive Dynamics (GUARD), a novel framew
ork for memorization mitigation in text-to-image diffusion models. GUARD adjusts
 the image denoising process to guide the generation away from an original train
ing image and towards one that is distinct from training data while remaining a
ligned with the prompt, guarding against reproducing training data, without hurt
ing image generation quality.
We propose a concrete instantiation of this framework, where the positive target
 that we steer towards is given by a novel method for (cross) attention attenua
tion based on (i) a novel statistical mechanism that automatically identifies th
e prompt positions where cross attention must be attenuated and (ii) attenuating
 cross-attention in these per-prompt locations.
The resulting GUARD offers a surgical, dynamic per-prompt inference-time approac
h that, we find, is by far the most robust method in terms of consistently produ
cing state-of-the-art results for memorization mitigation across two architectur
es and for both verbatim and template memorization, while also improving upon or
 yielding comparable results in terms of image quality.

Probing How Scalable Table Data Enhances General Long-Context Reasoning
Huaibing Xie, Guoliang Zhao, Yang Liu, Shihan Dou, Siming Huang, Yanling Xiao, S
haolei Wang, Yiting Liu, Cheng Zhang, Shaofan Liu, Pluto Zhou
As real-world tasks grow increasingly complex, long-context reasoning has become
 a core capability for Large Language Models (LLMs). However, few studies explor
e which data types are effective for long-context reasoning and why. We find tha
t structured table data with periodic structures shows strong potential for long
-context reasoning. Motivated by this observation, we mathematically analyze tab
ular dependency structures using mutual information, revealing periodic non-vani
shing dependencies in table data. Furthermore, we systematically analyze the cap
abilities of structured table data, conduct relevant scaling experiments, and va
lidate its underlying mechanisms for enhancing long-context reasoning, yielding
several meaningful insights. Leveraging these insights, we propose a simple yet
scalable pipeline(TableLong) for synthesizing high-quality, diverse, and verifia
ble structured table data to boost long-context reasoning via RL. Extensive expe
rimental results demonstrate that table data significantly enhances the long-con
text reasoning capability of LLMs across multiple long-context benchmarks (+8.24
\% on average), and even improves performance on out-of-domain benchmarks (+8.06
\% on average). We hope that our insights provide practical guidance for effecti
ve post-training data to enhance long-context reasoning in LLMs.
****
Training-Free Rate-Distortion-Perception Traversal With Diffusion
Yuhan Wang, Suzhi Bi, Ying-Jun Angela Zhang
The rate-distortion-perception (RDP) tradeoff characterizes the fundamental limi
ts of lossy compression by jointly considering bitrate, reconstruction fidelity,
 and perceptual quality. While recent neural compression methods have improved p
erceptual performance, they typically operate at fixed points on the RDP surface
, requiring retraining to target different tradeoffs. In this work, we propose a
 training-free framework that leverages pre-trained diffusion models to traverse
 the entire RDP surface. Our approach integrates a reverse channel coding (RCC)

module with a novel score-scaled probability flow ODE decoder. We theoretically prove that the proposed diffusion decoder is optimal for the distortion-perception tradeoff under AWGN observations and that the overall framework with the RCC module achieves the optimal RDP function in the Gaussian case. Empirical results across multiple datasets demonstrate the framework's flexibility and effectiveness in navigating the ternary RDP tradeoff using pre-trained diffusion models. Our results establish a practical and theoretically grounded approach to adaptive, perception-aware compression.

Message Passing on the Edge: Towards Scalable and Expressive GNNs
Pablo Barcelo, Fabian Jogl, Alexander Kozachinskiy, Matthias Lanzinger, Stefan Neumann, Cristobal Rojas
Graph neural networks (GNNs) are widely used in graph learning and most architectures propagate information by passing messages between vertices. In this work, we shift our attention to GNNs that perform message passing on *edges* and introduce EB-1WL, an edge-based color-refinement test, and a corresponding architecture, EB-GNN. Our EB-GNN architecture is inspired by the classic triangle-counting algorithm of Chiba and Nishizeki and passes messages along edges and triangles.

Our contributions are as follows:
1. Theoretically, we show that EB-1WL is significantly more expressive than 1WL. We provide a complete logical characterization of EB-1WL in first-order logic, along with distinguishability results via homomorphism counting. To the best of our knowledge, EB-GNN has the strongest theoretical expressivity guarantees among edge-based message-passing GNNs in the literature.
2. Unlike many GNN architectures that are more expressive than 1WL, we prove that EB-1WL and EB-GNN admit near-linear time and memory usage on practical graph learning workloads.
3. We show in experiments that EB-GNN is a highly efficient general-purpose architecture: it substantially outperforms simple MPNNs and remains competitive with task-specialized state-of-the-art GNNs at substantially lower computational cost.

Geometric Pocket-Centric Protein Encoding for Polypharmacology-Guided Multi-Target Drug Design
Haoran liu, Xiaoli Lin, Jing Hu, Yu Zou, Xiaolong Zhang
Polypharmacology provides a powerful strategy for treating complex diseases, but identifying molecules that simultaneously satisfy coupled constraints across multiple biological targets remains difficult. Existing methods typically model protein pockets in isolation and struggle to jointly account for multiple heterogeneous binding sites when designing a single shared ligand. To address these limitations, we propose a pocket-structure-centric generative framework for polypharmacology. This framework introduces a novel protein topological representation that selectively masks ligand-irrelevant residues while explicitly modeling backbone folding geometry and inter-residue spatial proximity within binding pockets. In addition, structural representations are jointly fused with amino acid and nucleotide sequences to capture their complementary information across targets. Experiments on COVID-19, schizophrenia, and tumor targets show that this framework generates valid candidates with significantly improved binding affinities compared to state-of-the-art methods.
****
PATRA: Pattern-Aware Alignment and Balanced Reasoning for Time Series Question Answering
Junkai Lu, Peng Chen, Xingjian Wu, Yang Shu, Chenjuan Guo, Christian S. Jensen, Bin Yang
Time series reasoning demands both the perception of complex dynamics and logical depth. However, existing LLM-based approaches exhibit two limitations: they often treat time series merely as text or images, failing to capture the patterns like trends and seasonalities needed to answer specific questions; and when trai

ned on a mix of simple and complex tasks, simpler objectives often dominate the learning process, hindering the development of deep reasoning capabilities. To address these limitations, we propose the Pattern-Aware Alignment and Balanced Reasoning model (PATRA), introducing a pattern-aware mechanism that extracts trend and seasonality patterns from time series to achieve deep alignment. Furthermore, we design a task-aware balanced reward to harmonize learning across tasks of varying difficulty, incentivizing the generation of coherent Chains of Thought. Extensive experiments show that PATRA outperforms strong baselines across diverse Time Series Question Answering (TSQA) tasks, demonstrating superior cross-modal understanding and reasoning capability.
****

Zeus: Towards Tuning-Free Foundation Model for Time Series Analysis
Yisong Fu, Zezhi Shao, Chengqing Yu, Yujie Li, Yongjun Xu, Xueqi Cheng, Fei Wang
We present Zeus, a unified tuning-free Time Series Foundation Model (TSFM) that delivers superior performance across diverse analysis tasks without any task-specific fine-tuning. Unlike prior studies that primarily focus on zero-shot forecasting but require task-specific tuning for other tasks, Zeus bridges this gap by addressing two fundamental challenges in multi-task generalization. First, to reconcile point-level granularity with long-sequence scalability, Zeus incorporates a multi-scale Transformer featuring point-wise tokenization and a U-shaped hierarchy, effectively balancing fine-grained fidelity with computational efficiency. Second, to accommodate varying inductive biases across different tasks, Zeus introduces Multi-Objective Temporal Masking (MOTM), a unified strategy that supports heterogeneous tasks (e.g., extrapolation, interpolation, and global abstraction) within a single framework. Extensive experiments across five representative tasks demonstrate that Zeus consistently achieves competitive results in tuning-free settings, underscoring its potential as a general-purpose TSFM. The code is available at https://github.com/GestaltCogTeam/Zeus.

From Prior to Pro: Efficient Skill Mastery via Distribution Contractive RL Finetuning
Zhanyi Sun, Shuran Song
We introduce Distribution Contractive Reinforcement Learning (DICE-RL), a framework that uses reinforcement learning (RL) as a "distribution contraction" operator to refine pretrained generative robot policies. DICE-RL turns a pretrained behavior prior into a high-performing "pro" policy by amplifying high-success behaviors from online feedback. We pretrain a diffusion- or flow-based policy for broad behavioral coverage, then finetune it with a stable, sample-efficient residual off-policy RL framework that combines selective behavior regularization with value-guided action selection. Extensive experiments and analyses show that DICE-RL reliably improves performance with strong stability and sample efficiency. It enables mastery of complex long-horizon manipulation skills directly from high-dimensional pixel inputs, both in simulation and on a real robot. Project website: [dice.rl.2026](https://zhanyisun.github.io/dice.rl.2026/).

Linear Regression with Unknown Truncation Beyond Gaussian Features
Alexandros Kouridakis, Anay Mehrotra, Alkis Kalavasis, Constantine Caramanis
In truncated linear regression, samples (x,y) are shown only when the outcome y falls inside a certain survival set $S^\star$ and the goal is to estimate the unknown d-dimensional regressor $w^\star$. This problem has a long history of study in Statistics and Machine Learning going back to the works of (Galton, 1897; Tobin, 1958) and more recently in, e.g., (Daskalakis et al., 2019; 2021; Lee et al., 2023; 2024). Despite this long history, however, most prior works are limited to the special case where $S^\star$ is precisely known. The more practically relevant case, where $S^\star$ is unknown and must be learned from data, remains open: indeed, here the only available algorithms require strong assumptions on the distribution of the feature vectors (e.g., Gaussianity) and, even then, have a $d^{\mathrm{poly} (1/\varepsilon)}$ run time for achieving ε accuracy. In this work, we give the first algorithm for truncated linear regression with unknown survival set that runs in $\mathrm{poly} (d/\varepsilon)$ tim

e, by only requiring that the feature vectors are sub-Gaussian. Our algorithm re lies on a novel subroutine for efficiently learning unions of a bounded number o f intervals using access to positive examples (without any negative examples) un der a certain smoothness condition. This learning guarantee adds to the line of works on positive-only PAC learning and may be of independent interest.

Skip-It? Theoretical Conditions for Layer Skipping in Vision–Language Models
Max Hartman, Vidhata Jayaraman, Moulik Choraria, Akhil Bhimaraju, Lav R. Varshne y

Vision–language models achieve incredible performance across a wide range of tas ks, but their large size makes inference costly. Recent work has shown that mult imodal processing contains significant redundancies, making it possible to skip certain layers with minimal performance loss. Yet current pruning techniques rem ain ad-hoc, relying on heuristics or hyperparameter sweeps rather than principle d criteria for determining when layer skipping is beneficial. In this paper, we propose a unified framework that characterizes the redundancy conditions under w hich pruning can enhance efficiency without sacrificing performance. Central to our approach are experimentally verifiable and interpretable notions of redundan cy that can be evaluated without requiring downstream task performance as a metr ic. Applying this framework, we corroborate prior findings that both early and l ate vision tokens are redundant across models, and we validate our conditions by showing they align with actual performance degradation. Beyond these empirical results, our framework provides a theoretically grounded understanding of redund ancy in VLMs and unifies many of the ideas behind modern layer-skipping techniqu es.

Similarity Is Not Logic: Factored Inference for Dual-Encoder Vision-Language Mod els

Sultan Alshehri, Zhantao Yang, Han Zhang, Marios Savvides

Dual-encoder vision-language models (VLMs) expose a similarity interface that en ables zero-shot retrieval but fails compositional constraints: queries like “umb rella and no person” retrieve images containing both, even when concept detectio n is reliable. We trace this to an interface-level **Bag-of-Concepts** effect, w here similarity scores approximate mean pooling of concept evidence regardless o f operators. Although operator-dependent signals exist in text embeddings, they are too weak or misaligned to affect rankings. Fine-tuning does not reliably res olve this failure because the dominant bottleneck is how similarity aggregates e vidence rather than what encoders represent. We propose **factored inference**, which separates evidence extraction from constraint execution, and introduce LCS E (Logic-Constrained Score Editing), a training-free method that executes constr aints externally using concept scores from frozen encoders. We also introduce FA CTOR-Bench, where LCSE achieves 85.5% accuracy versus 73.2% for the best fine-tu ned baseline, 90.7% when applied to SigLIP 2, and improves NegBench COCO MCQ acc uracy from 27.2% to 65.2% while preserving retrieval performance.

The Implicit Bias of Adam and Muon on Smooth Homogeneous Neural Networks
Eitan Gronich, Gal Vardi

We study the implicit bias of momentum-based optimizers on smooth homogeneous mo dels. We show that *momentum steepest descent* algorithms like Muon (spectral no rm), MomentumGD (ℓ_2 norm), and Signum (ℓ_∞ norm) are *approximat e* steepest descent trajectories under a decaying learning rate schedule, provin g that these algorithms have a bias towards KKT points of the corresponding marg in maximization problem. We extend the analysis to Adam (without the stability c onstant), which maximizes the ℓ_∞ margin, and to Muon-Signum and Muon-Adam, which maximize a hybrid norm. Our experiments corroborate the theory and s how that the identity of the margin maximized depends on the choice of optimizer . Overall, our results extend earlier lines of work on steepest descent in homog eneous models and momentum-based optimizers in linear models.

RADE: Random Add-Drop Edge as a Regularizer

Danial Saber, Amirali Salehi-Abari
Graph Neural Networks (GNNs) suffer from overfitting and over-squashing of long-range information. Stochastic graph augmentations (e.g., edge deletion) regularize training against overfitting but can introduce train-inference misalignment and do not improve over-squashing. In contrast, rewiring methods improve connectivity to mitigate over-squashing, but are not designed to regularize training. We propose *Random Add-Drop Edge (RADE)*, a stochastic graph augmentation method that jointly drops and adds edges to address both overfitting and over-squashing simultaneously. RADE is provably designed to align training and inference so that random augmentations regularize training without distribution shift, while supporting long-range communication at inference. We further propose and study a mini-batch gradient-norm balancing algorithm that adapts deletion and addition rates during training, rendering RADE hyperparameter-free in practice. Experiments on node- and graph-classification benchmarks show that RADE is a strong regularizer and mitigates over-squashing. Ablations support the roles of train-inference alignment, adaptive rate selection, and the complementary effects of random edge deletion and edge addition.

When Do Graph Foundation Models Transfer? A Data-Centric Theory
Jiajun Zhu, Ying Chen, Peihao Wang, Yixuan He, Pan Li, Aditya Akella, Zhangyang Wang
Graph foundation models (GFMs) aim to reuse a single backbone across diverse graph domains, yet their transfer is often uneven and can exhibit negative transfer. While most prior work improves transfer through architectural or adaptation choices, we ask a data-centric question: *which properties of two graph domains determine how much a fixed representation model changes its outputs?* Using a graphon-based continuous limit for dense graphs, we show that for both set-based and message-passing tokenizations, any Lipschitz backbone admits an explicit decomposition of cross-domain output shift into (i) graph-specific finite-sample approximation terms and (ii) an intrinsic, relabeling-invariant domain discrepancy capturing structural mismatch. A key ingredient is positional-encoding (PE) stability: we establish stability guarantees for spectral PEs and highlight contrasting behaviors of eigenvector- versus subspace-based PEs. Experiments on synthetic and real graphs validate the theory and translate the decomposition into guidance for data curation in GFM transfer.

Autoregressive Direct Preference Optimization
Masanari Oi, Mahiro Ukai, Masahiro Kaneko, Naoaki Okazaki, Nakamasa Inoue
Direct preference optimization (DPO) has emerged as a promising approach for aligning large language models (LLMs) with human preferences.
However, the widespread reliance on the response-level Bradley-Terry (BT) model may limit its full potential, as the reference and learnable models are assumed to be autoregressive only after deriving the objective function.
Motivated by this limitation, we revisit the theoretical foundations of DPO and propose a novel formulation that explicitly introduces the autoregressive assumption prior to applying the BT model.
By reformulating and extending DPO, we derive a novel variant, termed Autoregressive DPO (ADPO), that explicitly integrates autoregressive modeling into the preference optimization framework.
Without violating the theoretical foundations, the derived loss takes an elegant form: it shifts the summation operation in the DPO objective outside the log-sigmoid function.
Furthermore, through theoretical analysis of ADPO, we show that there exist two length measures to be considered when designing DPO-based algorithms: the token length μ and the feedback length μ'.
To the best of our knowledge, we are the first to explicitly distinguish these two measures and analyze their implications for preference optimization in LLMs.

Approximate Equivariance via Projection-Based Regularisation
Torben Berndt, Jan Stühmer

Equivariance is a powerful inductive bias in neural networks, improving generalisation and physical consistency. Recently, however, non-equivariant models have regained attention, due to their better runtime performance and imperfect symmetries that might arise in real-world applications. This has motivated the development of approximately equivariant models that strike a middle ground between respecting symmetries and fitting the data distribution. Existing approaches in this field either rely on sampling from a group, incurring a high sample complexity, or explicitly parameterise a model as a sum of an equivariant and non-equivariant network.

This work instead approaches approximate equivariance via a projection-based regulariser which leverages a layer-wise orthogonal decomposition of a network's layers into equivariant and non-equivariant components. In contrast to existing methods, this penalises non-equivariance at an operator level across the full group orbit, rather than point-wise as in sample-based approaches. We present a mathematical framework for computing the non-equivariance penalty exactly and efficiently in both the spatial and spectral domains. In our experiments, our method consistently outperforms prior approximate equivariance approaches in both model performance and efficiency, achieving substantial runtime gains over sample-based regularisers.

VideoTemp-o3: Harmonizing Temporal Grounding and Video Understanding in Agentic Thinking-with-Videos

Wenqi Liu, Yunxiao Wang, Shijie Ma, Meng Liu, Qile Su, Tianke Zhang, Haonan fan, Changyi Liu, Kaiyu Jiang, Jiankang Chen, Kaiyu Tang, Bin Wen, Fan Yang, Tingting Gao, Han Li, Yinwei Wei, Xuemeng Song

In long-video understanding, conventional uniform frame sampling often fails to capture key visual evidence, leading to degraded performance and increased hallucinations. To address this, recent agentic thinking-with-videos paradigms have emerged, adopting a localize–clip–answer pipeline in which the model actively identifies relevant video segments, performs dense sampling within those clips, and then produces answers. However, existing methods remain inefficient, suffer from weak localization, and adhere to rigid workflows. To solve these issues, we propose VideoTemp-o3, a unified agentic thinking-with-videos framework that jointly models video grounding and question answering. VideoTemp-o3 exhibits strong localization capability, supports on-demand clipping, and can refine inaccurate localizations. Specifically, in the supervised fine-tuning stage, we design a unified masking mechanism that encourages exploration while preventing noise. For reinforcement learning, we introduce dedicated rewards to mitigate reward hacking. Besides, from the data perspective, we develop an effective pipeline to construct high-quality long video grounded QA data, along with a corresponding benchmark for systematic evaluation across various video durations. Experimental results demonstrate that our method achieves remarkable performance on both long video understanding and grounding.

FG-CLIP 2: A Bilingual Fine-grained Vision-Language Alignment Model

Chunyu Xie, Bin Wang, Fanjing Kong, Jincheng Li, Dawei Liang, Ji Ao, Dawei Leng, Yuhui Yin

Fine-grained vision-language understanding requires precise alignment between visual content and linguistic descriptions, a capability that remains limited in current models, particularly in non-English settings. While models like CLIP perform well on global alignment, they often struggle to capture fine-grained details in object attributes, spatial relations, and linguistic expressions, with limited support for bilingual comprehension. To address these challenges, we introduce FG-CLIP 2, a bilingual vision-language model designed to advance fine-grained alignment for both English and Chinese. Our approach leverages rich fine-grained supervision, including region-text matching and long-caption modeling, alongside multiple discriminative objectives. We further introduce the Textual Intra-modal Contrastive (TIC) loss to better distinguish semantically similar captions. Trained on a carefully curated mixture of large-scale English and Chinese data, including a newly released 12M Chinese region-text dataset, FG-CLIP 2 achieves p

owerful bilingual performance. To enable rigorous evaluation, we present a new b enchmark for Chinese multimodal understanding, featuring long-caption retrieval and bounding box classification. Extensive experiments on 29 datasets across 8 t asks show that FG-CLIP 2 outperforms existing methods, achieving state-of-the-ar t results in both languages. We release the model, code, and benchmark to facili tate future research on bilingual fine-grained vision-language alignment.

Judging What We Cannot Solve: A Consequence-Based Approach for Oracle-Free Evalu ation of Research-Level Math
Guijin Son, Donghun Yang, Hitesh Laxmichand Patel, Hyunwoo Ko, Amit Agarwal, Sun ghee Ahn, Kyong-Ha Lee, Youngjae Yu
Recent progress in reasoning models suggests that generating plausible attempts for research-level mathematics may be within reach, but verification remains a b ottleneck, consuming scarce expert time. We hypothesize that a meaningful soluti on should contain enough method-level information that, when applied to a neighb orhood of related questions, it should yield better downstream performance than incorrect solutions. Building on this idea, we propose \textbf{Consequence-Based Utility}, an oracle-free evaluator that scores each candidate by testing its va lue as an in-context exemplar in solving related yet verifiable questions. Our a pproach is evaluated on an original set of research-level math problems each pai red with one expert-written solution and nine LLM-generated solutions. Notably, Consequence-Based Utility consistently outperforms reward models, generative rew ard models, and LLM judges on ranking quality. Specifically, for GPT-OSS-120B it improves Acc@1 from 67.2 to 76.3 and AUC from 71.4 to 79.6, with similarly larg e AUC gains on GPT-OSS-20B (69.0 to 79.2). Furthermore, compared to LLM-Judges, it also exhibits a larger solver–evaluator gap, maintaining stronger correct–wro ng separation even on instances the underlying solver often fails to solve.

Interactive Person Retrieval via Multi-Turn Multimodal Conversation
Yang Bai, Tingfeng Wang, Bin Yang, Min Cao, Jinqiao Wang, Mang Ye
Traditional text-based person retrieval approaches typically rely on single-shot textual queries, which are generally incomplete or vague in real-world scenario s. Recently, chat-based person retrieval methods enable iterative query refineme nt via question-answering interactions between the system and users. However, th ese methods fall short of direct user interaction with retrieved candidates duri ng conversation, making it challenging to effectively refine the retrieval resul ts. To address these limitations, we propose multimodal interactive person retri eval (MInterPR), a new retrieval paradigm that allows users to iteratively refin e retrieved candidates by providing feedback on visual differences from the targ et person. To support this task, we establish MInterPEDES, a multimodal conversa tional dataset constructed by augmenting existing question-answering dialogues w ith synthesized visual feedbacks. Furthermore, to tackle the challenge of accura te and efficient semantics understanding in multimodal dialogues, we propose a m ultimodal conversational memory-enhanced framework MNEMO, which incorporates an atomic turn encoding (ATE) module to model each dialogue turn independently, and a dialogue memory aggregation (DMA) module to capture the fine-grained informat ion and cross-turn dependencies. Extensive experiments demonstrate that MNEMO ac hieves substantial improvements in both retrieval accuracy and generalization ab ility, highlighting its promising potential in real-world scenarios. The code an d dataset are publicly available at https://github.com/Flame-Chasers/MNEMO.

Positive Distribution Shift as a Framework for Understanding Tractable Learning
Marko Medvedev, Idan Attias, Elisabetta Cornacchia, Theodor Misiakiewicz, Gal Va rdi, Nathan Srebro
We study a setting where the goal is to learn a target function f(x) with respec t to a target distribution D(x), but training is done on i.i.d. samples from a d ifferent training distribution D′(x), labeled by the true target f(x). Such a d istribution shift (here in the form of covariate shift) is usually viewed negati vely, as hurting or making learning harder, and the traditional distribution shi ft literature is mostly concerned with limiting or avoiding this negative effect

. In contrast, we argue that with a well-chosen D'(x), the shift can be positive and make learning easier -- a perspective called Positive Distribution Shift (PDS). Such a perspective is central to contemporary machine learning, where much of the innovation is in finding good training distributions D’(x), rather than changing the training algorithm. We further argue that the benefit is often computational rather than statistical, and that PDS allows computationally hard problems to become tractable even using standard gradient-based training. We formalize different variants of PDS, show how certain hard classes are easily learnable under PDS, and make connections with membership query learning.

ViEEG: Hierarchical Visual Neural Representation for EEG Brain Decoding
Minxu Liu, Donghai Guan, Chuhang Zheng, Chunwei Tian, Jie Wen, Qi Zhu
Understanding and decoding brain activity into visual representations is a fundamental challenge at the intersection of neuroscience and artificial intelligence. While electroencephalogram (EEG) visual decoding has shown promise due to its non-invasive and low-cost nature, existing methods suffer from {Hierarchical Neural Encoding Neglect (HNEN)}, a critical limitation in which flat neural representations fail to model the brain’s hierarchical visual processing. Inspired by the hierarchical organization of visual cortex, we propose ViEEG, a neuro-inspired framework that addresses HNEN. ViEEG decomposes each visual stimulus into three biologically aligned components, namely contour, foreground object, and contextual scene, which serve as anchors for a three-stream EEG encoder. These EEG features are progressively integrated via cross-attention routing, simulating cortical information flow from low-level to high-level vision. We further adopt hierarchical contrastive learning for EEG-CLIP representation alignment, enabling zero-shot object recognition. Extensive experiments on THINGS-EEG dataset demonstrate that ViEEG significantly outperforms previous methods by a large margin in both subject-dependent and subject-independent settings. Results on THINGS-MEG dataset further confirm ViEEG's generalization to different neural modalities. ViEEG not only advances the performance frontier but also sets a new paradigm for EEG brain visual decoding. Our code is available at https://github.com/LauMason/ViEEG.

Unfolded Laplacian Spectral Embedding: A Theoretically Grounded Approach to Dynamic Network Representation
Haruka Ezoe, Hiroki Matsumoto, Ryohei Hisano
Dynamic relational data arise in many machine learning applications, yet their evolving structure poses challenges for learning representations that remain consistent and interpretable over time. A common approach is to learn time varying node embeddings, whose usefulness depends on well defined stability properties across nodes and across time. We introduce Unfolded Laplacian Spectral Embedding (ULSE), a principled extension of unfolded adjacency spectral embedding to normalized Laplacian operators, a setting where stability guarantees have remained out of reach. We prove that ULSE satisfies both cross-sectional and longitudinal stability under a dynamic stochastic block model. Moreover, the Laplacian formulation yields a dynamic Cheeger-type inequality linking the spectrum of the unfolded normalized Laplacian to worst case conductance over time, providing structural insight into the embeddings. Empirical results on synthetic and real-world dynamic networks validate the theory.

Tracing the Dynamics of Refusal: Exploiting Latent Refusal Trajectories for Robust Jailbreak Detection
Xulin Hu, CHE WANG, Wei Yang Bryan Lim, Jianbo Gao, Zhong Chen
Representation Engineering analyses often characterize refusal using static directions extracted from terminal or pooled representations. We ask whether this view misses how refusal is constructed across layer-token positions. Using causal tracing, we identify a Refusal Trajectory: a sparse upstream activation pattern that often persists even when attacks such as GCG suppress terminal refusal signals. Based on this observation, we propose SALO (Sparse Activation Localization Operator), a lightweight white-box detector that operates on raw hidden-state vo

lumes from a selected layer window. Across Qwen, Llama, and Mistral models, SALO improves jailbreak detection on several attack families under a fixed XSTest-calibrated operating point. We further analyze static RepE-style baselines, ROI sensitivity, adaptive GCG attacks, and encoded-input boundary cases, clarifying both the promise and limitations of refusal-trajectory monitoring.

Graph-Preference Learning: Debiasing Network-Sampled Human Feedback for Target Welfare Estimation

Guangrui Fan, DanDan Liu, AZNUL QALID MD SABRI, Pan Lihu

Preference-based reward modeling is a core component of RLHF and DPO pipelines. In practice, the humans providing preference feedback are rarely an i.i.d. sample: recruitment and exposure often follow social, institutional, or spatial structure, inducing non-uniform inclusion probabilities that correlate with graph centrality. We formalize preference learning with *network-sampled* annotators and show that identity-agnostic scalar reward modeling implicitly represents an inclusion-weighted welfare, over-representing structurally central communities when the inclusion distribution q differs from a designer-chosen target weighting π. We propose Graph-Preference Learning, which combines (i) a graph-personalized reward model that shares statistical strength across neighboring annotators and (ii) graph-balanced aggregation that computes stabilized importance weights to target π. Our analysis characterizes the induced welfare represented by the learned aggregate reward and bounds its deviation from the target in terms of weight mismatch, reward-model approximation, and finite-sample effects. Experiments on synthetic graphs and a *semi-synthetic* case study on the LMArena preference dataset, where biased inclusion is *induced* via graph-based sampling, demonstrate up to 62% reduction in target-welfare recovery error and 17% reduction in cross-language performance gaps under biased inclusion.

Memory as Dynamics: Learning Reliability-Guided Predictive Models for Online Video Perception

Minwoo Kim, Sang Min Yoon

Predictive memory has recently emerged as a powerful mechanism for online video models, enabling temporal reasoning beyond static memory banks. However, we observe a paradoxical phenomenon in which predictive memory often exacerbates drift under occlusion or rapid motion, as inaccurate predictions contaminate the internal state and lead to irreversible identity loss. We identify this failure as a reliability mismatch: predictive dynamics are applied uniformly despite high uncertainty and weak observations.

To address this issue, we reinterpret video memory as a dynamic latent process rather than a static buffer. Building on this insight, we introduce Reliability-Guided Predictive Memory (RPM), a framework that explicitly regulates when and how predictive dynamics should influence online video perception. RPM integrates a latent world model based on state-space dynamics to generate predictive priors, while employing a reliability-aware fusion policy that suppresses unreliable predictions during occlusion.

We instantiate RPM on a SAM2-based model and evaluate it on visual object tracking benchmarks. Experiments demonstrate that our method reduces drift after occlusion, consistently outperforming strong baselines that rely on either static memory or unconditional predictive modeling. We further show that this reliability-guided mechanism transfers to video object segmentation across multiple standard benchmarks. These findings establish that predictive memory is beneficial only when its reliability is explicitly modeled, and define a general principle for robust online video perception. The code is available at https://github.com/minwookim01/memory-as-dynamics.

On the Salience of Low-Probability Tokens for AI-Generated Text Detection: A Multiscale Uncertainty Perspective

Yikai Guo, Bin Wang, Xilai Fan, Wenjun Ke, Haoran Luo

AI-generated text increasingly blends with human writing, raising practical risks such as misinformation, academic misuse, and corpora contamination. While stat

istical detectors are appealing for efficiency and generalization, they suffer f
rom two key limitations. (i) Boilerplate dominance, boilerplate tokens shared ac
ross human and LLM writing can overwhelm discriminative signals. (ii) Brittle po
int estimates, relying on a single probability score yields unstable decisions u
nder adversarial manipulations. To address these issues, we propose $\textbf{Unc
ertainty}$, a multiscale uncertainty estimator that focuses on informative low-p
robability tokens, which more clearly expose distributional discrepancies. Local
ly, it alleviates boilerplate dominance by averaging the log-probabilities of lo
w-probability tokens; globally, it reduces brittleness by capturing the distribu
tional shape of this low-probability region via Rényi entropy. We further extend
 the detector to $\textbf{Uncertainty++}$ via conditional independent sampling,
yielding a more stable uncertainty estimation. Experiments across seven datasets
 and sixteen LLMs demonstrate high effectiveness, generalization, and robustness
. Our code is available at github.com/guoyikai2000/Uncertainty-AIGT.

Variational Entropic Optimal Transport

Roman Dyachenko, Nikita Gushchin, Kirill Sokolov, Petr Mokrov, Evgeny Burnaev, A
lexander Korotin

Entropic optimal transport (EOT) in continuous spaces with quadratic cost is a c
lassical tool for solving the domain translation problem. In practice, recent ap
proaches optimize a weak dual EOT objective depending on a single potential, but
 doing so is computationally not efficient due to the intractable log-partition
term. Existing methods typically resolve this obstacle in one of two ways: by si
gnificantly restricting the transport family to obtain closed-form normalization
 (via Gaussian-mixture parameterizations), or by using general neural parameteri
zations that require simulation-based training procedures. We propose Variationa
l Entropic Optimal Transport (VarEOT), based on an exact variational reformulati
on of the log-partition $\log \mathbb{E}[\exp(\cdot)]$ as a tractable minimizati
on over an auxiliary positive normalizer. This yields a differentiable learning
objective optimized with stochastic gradients and avoids the necessity of MCMC s
imulations during the training. We provide theoretical guarantees, including fin
ite-sample generalization bounds and approximation results under universal funct
ion approximation. Experiments on synthetic data and unpaired image-to-image tra
nslation demonstrate competitive or improved translation quality, while comparis
ons within the solvers that use the same weak dual EOT objective support the ben
efit of the proposed optimization principle.
****

Mitigating Reward Hacking in RLHF via Bayesian Non-negative Reward Modeling

Zhibin Duan, Guowei Rong, Zhuo Li, Bo Chen, Mingyuan Zhou, Dandan Guo

Reward models learned from human preferences are central to aligning large langu
age models (LLMs) via reinforcement learning from human feedback, yet they are o
ften vulnerable to reward hacking due to noisy annotations and systematic biases
 such as response length or style. We propose Bayesian Non-Negative Reward Model
 (BNRM), a principled reward modeling framework that integrates non-negative fac
tor analysis into Bradley–Terry (BT) preference model.BNRM represents rewards th
rough a sparse, non-negative latent factor generative process that operates at t
wo complementary levels: instance-specific latent variables induce disentangled
reward representations, while sparsity over global latent factors acts as an imp
licit debiasing mechanism that suppresses spurious correlations. Together, this
disentanglement-then-debiasing structure enables robust uncertainty-aware reward
 learning. To scale BNRM to modern LLMs, we develop an amortized variational inf
erence network conditioned on deep model representations, allowing efficient end
-to-end training. Extensive empirical results demonstrate that BNRM substantiall
y mitigates reward over-optimization, improves robustness under distribution shi
fts, and yields more interpretable reward decompositions than strong baselines.

Generalized Linear Bandits with Memory

Heesang Ann, Hyunjun Choi, Taehyun Hwang, Younghoon Shin, Haeju Cheong, Min-hwan
 Oh

We study generalized linear bandits with memory, an endogenous non-stationary se

tting in which rewards depend on past actions through a finite memory matrix. Bu ilding on prior work for linear models Clerici et al.,(2024), we show that the p reviously known $\tilde{\mathcal{O}}(T^{3/4})$ regret bound stems from a loose a nalysis, and we provide a sharpened analysis that recovers a $\tilde{\mathcal{O} }(\sqrt{T})$ regret rate in the linear case. We then extend this improvement to generalized linear models and propose a block-wise algorithm based on shrunken c onfidence bounds. Our algorithm achieves a regret bound of $\tilde{\mathcal{O}}\ left(\sqrt{mT} + d\sqrt{T} + \sqrt{\kappa}d^{2} m^{1/4} T^{1/4} + \kappa d^{2} \ right)$, where d denotes the feature dimension, m the memory length, and $\k appa$ a curvature parameter of the link function. This attains a $\sqrt{T}$-type rate despite nonlinear rewards and memory effects. To the best of our knowledge , this analysis provides a unified treatment of memory-induced non-stationarity and nonlinear link functions, while ensuring that the leading regret term is ind ependent of the curvature of the link function. We conduct numerical experiments that are consistent with our theoretical findings.

Riemannian MeanFlow for One-Step Generation on Manifolds

Zichen Zhong, Haoliang Sun, Yukun Zhao, Yongshun Gong, Yilong Yin

Flow Matching enables simulation-free training of generative models on Riemannia n manifolds, yet sampling typically still relies on numerically integrating a pr obability-flow ODE. We propose Riemannian MeanFlow (RMF), extending MeanFlow to manifold-valued generation where velocities lie in location-dependent tangent sp aces. RMF defines an average-velocity field via parallel transport and derives a Riemannian MeanFlow identity that links average and instantaneous velocities fo r intrinsic supervision. We make this identity practical in a log-map tangent re presentation, avoiding trajectory simulation and heavy geometric computations. F or stable optimization, we decompose the RMF objective into two terms and apply conflict-aware multi-task learning to mitigate gradient interference. RMF also s upports conditional generation via classifier-free guidance. Experiments on sphe res, tori, SO(3), and SE(3) demonstrate competitive one-step sampling with impro ved quality–efficiency trade-offs and substantially reduced sampling cost.

Generative Inverse Design with Abstention via Diagonal Flow Matching

Miguel de Campos, Werner Krebs, Hanno Gottschalk

Inverse design aims to find design parameters x achieving target performance $ y^*$. Generative approaches learn bidirectional mappings between designs and lab els, enabling diverse solution sampling. However, standard conditional flow matc hing (CFM), when adapted to inverse problems by pairing labels with design param eters, exhibits strong sensitivity to their arbitrary ordering and scaling, lead ing to unstable training. We introduce Diagonal Flow Matching (Diag--CFM), which resolves this through a zero-anchoring strategy that pairs design coordinates w ith noise and labels with zero, making the learning problem provably invariant t o coordinate permutations. This yields substantially lower round-trip error than CFM and invertible neural network baselines across design dimensions up to $P{= }784$, including order-of-magnitude gains on several benchmarks. We develop two architecture-intrinsic uncertainty metrics, Zero-Deviation and Self-Consistency, that enable three practical capabilities: selecting the best candidate among mu ltiple generations, abstaining from unreliable predictions, and detecting out-of -distribution targets; consistently outperforming ensemble and general-purpose a lternatives across all tasks. We validate on airfoil, gas turbine combustor, sca lable analytical benchmarks, a photonics inverse-design task, and an image-stati stics benchmark.

Are VLMs Seeing or Just Saying? Uncovering the Illusion of Visual Re-examination

Chufan Shi, Cheng Yang, Yaokang Wu, Linghao Jin, Bo Shui, Taylor Berg-Kirkpatric k, Xuezhe Ma

Vision-Language Models (VLMs) often produce self-reflective statements like “let me check the figure again” during reasoning. Do such state- ments trigger genui ne visual re-examination, or are they merely learned textual patterns? We in- ve stigate this via VISUALSWAP, an image-swap probing framework: after a model reas

ons over an image, we replace it with a visually similar but semantically differ
ent one and test whether the model notices. We introduce VS-BENCH, 800 image pai
rs curated from MathVista, Math- Verse, MathVision, and MMMU-Pro. Exper- iments
on Qwen3-VL, Kimi-VL, and ERNIE- VL reveal a striking failure: models overwhelm-
ingly miss the swap, with accuracy dropping by up to 60%. Counterintuitively, t
hinking mod- els are nearly 3x more vulnerable than their in- structed counterpa
rts, and scaling offers no mit- igation. Multi-turn user instructions restore vi
- sual grounding, but self-generated reflective state- ments during continuous g
eneration do not. At- tention analysis explains why: user instructions substanti
ally elevate attention to visual tokens, whereas self-reflection does not. Curre
nt VLMs tend to say rather than actually see when claiming to perform visual re-
examination. Our code and dataset are available at the project page: https://vis
ualswap.github.io/

Commit to the Bit: Reactive Reinforcement Learning Done Right
Onno Eberhard, Claire Vernade, Michael Muehlebach
Reinforcement learning algorithms are commonly analyzed (and designed) under the
Markov assumption. This is unrealistic, as most environments encountered in pra
ctice are either partially observable, or require function approximation that re
stricts the agent to access non-Markovian state features. We consider the proble
m of learning an optimal reactive policy in a finite environment with determinis
tic observations (or equivalently, hard state aggregation). We introduce a new a
lgorithm, _Committed Q-learning_, and prove almost-sure convergence to the optim
al reactive policy under an intuitive assumption we call _rewire-robustness_. Th
is assumption is strictly weaker than the $q_\star$-realizability condition used
in prior work. Our algorithm is a variant of classical Q-learning in which the
behavior policy commits to a single action upon entering a feature, and only res
amples actions when the observed feature changes. A crucial part of our analysis
is the introduction of _quasi-Markov_ environments.

Conditionally Site-Independent Neural Evolution of Antibody Sequences
Stephen Zhewen Lu, Aakarsh Vermani, Kohei Sanno, Jiarui Lu, Frederick A Matsen,
Milind Jagota, Yun S. Song
Common deep learning approaches for antibody engineering focus on modeling the m
arginal distribution of sequences. By treating sequences as independent samples,
however, these methods overlook affinity maturation as a rich and largely untap
ped source of information about the evolutionary process by which antibodies exp
lore the underlying fitness landscape. In contrast, classical phylogenetic model
s explicitly represent evolutionary dynamics but lack the expressivity to captur
e complex epistatic interactions. We bridge this gap with **CoSiNE**, a continuo
us-time Markov chain parameterized by a deep neural network. Mathematically, we
prove that CoSiNE provides a first-order approximation to the intractable seque
ntial point mutation process, capturing epistatic effects with an error bound th
at is quadratic in branch length. Empirically, CoSiNE outperforms state-of-the-a
rt language models in zero-shot variant effect prediction by explicitly disentan
gling selection from context-dependent somatic hypermutation. Finally, we introd
uce *Guided Gillespie*, a classifier-guided sampling scheme that steers CoSiNE a
t inference time, enabling efficient optimization of antibody binding affinity t
oward specific antigens.

Swordsman: Entropy-Driven Adaptive Block Partition for Efficient Diffusion Langu
age Models
Yu Zhang, Xinchen Li, Jialei Zhou, Hongnan Ma, Zhongwei Wan, Yiwei Shi, Duoqian
Miao, Qi Zhang, Longbing Cao
Block-wise decoding effectively improves the inference speed and quality in diff
usion language models (DLMs) by combining inter-block sequential denoising and i
ntra-block parallel unmasking. However, existing block-wise decoding methods typ
ically partition blocks in a rigid and fixed manner, which inevitably fragments
complete semantic or syntactic constituents, leading to suboptimal performance.
Inspired by the entropy reduction hypothesis (ERH), we recognize that constituen

t boundaries offer greater opportunities for uncertainty reduction, which motiva
tes us to employ entropy analysis for identifying constituent boundaries. Theref
ore, we propose Swordsman, an entropy-driven adaptive block-wise decoding framew
ork for DLMs. Swordsman adaptively partitions blocks by identifying entropy shif
ts between adjacent tokens to better align with semantic or syntactic constituen
t boundaries. In addition, Swordsman dynamically adjusts unmasking thresholds co
nditioned on the real-time unmasking status within a block, further improving bo
th efficiency and stability. As a training-free framework, supported by KV Cache
, Swordsman demonstrates state-of-the-art performance across extensive evaluatio
ns. Our code is now available.

Plan for Speed: Dilated Scheduling for Masked Diffusion Language Models
Omer Luxembourg, Haim H. Permuter, Eliya Nachmani
Masked diffusion language models (MDLMs) promise fast, non-autoregressive text g
eneration, yet existing samplers, which pick tokens to unmask based on model con
fidence, ignore interactions when unmasking multiple positions in parallel and e
ffectively reduce to slow, autoregressive behavior. We propose the Dilated Unmas
king Scheduler (DUS), an inference-only, planner-model-free method that partitio
ns sequence positions into non-adjacent dilated groups and unmasks them in paral
lel so as to minimize an upper bound on joint entropy gain at each denoising ste
p. By explicitly trading off the number of network calls against generation qual
ity, DUS recovers most of the performance lost under traditional parallel unmask
ing strategies. Across math (GSM8K, MATH500), code (HumanEval, MBPP), general-kn
owledge (BBH, MMLU-Pro), and instruction following (IFEval) benchmarks, DUS outp
erforms confidence-based planners and turns the diffusion-specific quality-speed
 trade-off into a deterministic, predictable speedup set by the block size B,
yielding up to $5.8\times$ wall-clock speedup over token-by-token MDLM decoding
without modifying the underlying denoiser. Applied as a drop-in post-filter, dil
ated spacing also improves adaptive samplers. Code is available at https://githu
b.com/omerlux/DUS.

Activation Oracles: Training and Evaluating LLMs as General-Purpose Activation E
xplainers
Adam Karvonen, James Chua, Clément Dumas, Kit Fraser-Taliente, Subhash Kantamnen
i, Julian Minder, Euan Ong, Arnab Sen Sharma, Daniel Wen, Owain Evans, Samuel Ma
rks
Large language model (LLM) activations are notoriously difficult to understand,
with most existing techniques using complex, specialized methods for interpretin
g them. Recent work has proposed a simpler approach known as LatentQA: training
LLMs to directly accept LLM activations as inputs and answer arbitrary questions
 about them in natural language. However, prior work has focused on narrow task
settings for both training and evaluation. In this paper, we instead take a gene
ralist perspective. We evaluate LatentQA-trained models, which we call Activatio
n Oracles (AOs), in far out-of-distribution settings and examine how performance
 scales with training data diversity. We find that AOs can recover information f
ine-tuned into a model (e.g., biographical knowledge or malign propensities) tha
t does not appear in the input text, despite never being trained with activation
s from a fine-tuned model. Our main evaluations are four downstream tasks where
we can compare to prior white- and black-box techniques. We find that even narro
wly-trained LatentQA models can generalize well, and that adding additional trai
ning datasets (such as classification tasks and a self-supervised context predic
tion task) yields consistent further improvements. Our best AOs match or exceed
white-box baselines on all four tasks and the best overall baseline on 3 of 4. T
hese results suggest that diversified training to answer natural-language querie
s imparts a general capability to verbalize information about LLM activations.

R-Diverse: Mitigating Diversity Illusion in Self-Play LLM Training
Gengsheng Li, Jinghan He, Shijie Wang, Ruiqi Liu, Renrui Zhang, Zijun Yao, Junfe
ng Fang, Haiyun Guo, Dan Zhang, Jinqiao Wang
Self-play bootstraps LLM reasoning through an iterative Challenger--Solver loop:

the Challenger is trained to generate questions that target the Solver's capabilities, and the Solver is optimized on the generated data to expand its reasoning skills. However, existing frameworks like R-Zero often exhibit non-sustained improvement, where early gains degrade as self-play continues. We identify a key failure mode, **Diversity Illusion**, where the Solver's training signals appear diverse yet collapse into recurring underlying patterns. It manifests as (1) *Local Diversity Illusion*, where diversity is enforced only within-batch, inducing cross-iteration mode cycling; and (2) *Surface Diversity Illusion*, where questions vary superficially but require near-identical reasoning skills. To mitigate them, we propose R-Diverse with two aligned innovations: **Memory-Augmented Penalty (MAP)**, which uses a persistent memory bank to discourage recycling across iterations, and **Skill-Aware Measurement (SAM)**, which evaluates diversity by the reasoning skills exercised rather than surface variation of questions. Across 10 math and general reasoning benchmarks, R-Diverse sustains gains over more iterations and consistently outperforms prior self-play methods.

ϕ-Balancing for Mixture-of-Experts Training

Lizhang Chen, Jonathan Li, Qi Wang, Runlong Liao, Shuozhe Li, Chen Liang, Ni Lao, qiang liu

Mixture-of-Experts (MoE) models rely on balanced expert utilization to fully realize their scalability. However, existing load-balancing methods are largely heuristic and operate on noisy mini-batch assignment statistics, introducing bias relative to population-level objectives. We propose **ϕ-balancing**, a principled framework that directly targets population-level expert balance by minimizing a strictly convex, symmetric, and differentiable potential of the expected routing distribution. Using convex duality, we derive an equivalent min-max formulation and obtain a simple online algorithm via mirror descent, yielding an efficient EMA-based routing adjustment with negligible overhead. Across large-scale pretraining and downstream fine-tuning, ϕ-balancing consistently outperforms prior Switch-style and loss-free baselines, demonstrating more stable and effective expert utilization.

Symbiosis-Inspired Knowledge Distillation for Incremental Object Detection

Mingyue Zeng, De Cheng, Zhipeng Xu, Huaijie Wang, Nannan Wang, Xinbo Gao

Incremental object detection (IOD) aims to extend detectors to new categories while retaining previously acquired knowledge. Existing methods often adopt a class incremental learning perspective, separating feature spaces to sharpen decision boundaries. However, this separation-oriented paradigm may overlook object symbiosis in detection, where co-occurrence and occlusion introduce spatial and semantic dependencies that benefit from shared representations. Ignoring these dependencies distorts the shared representations, exacerbates confusion between old and new classes, and accelerates catastrophic forgetting. To address this, we propose Symbiosis-Inspired Knowledge Distillation (SIKD), which explicitly leverages object symbiosis at two complementary levels. Spatial Symbiosis Distillation (SpSD) focuses on symbiotic regions where the old model responds with high overlap to objects in the new task. It preserves generalizable old class cues, suppresses class-specific bias and redundancy, and distills the refined evidence to the new model at matched spatial locations with slot-aligned supervision. Semantic Symbiosis Distillation (SeSD) maintains class level structure by forming confidence weighted prototypes for old classes and aligning their inter class soft ranks over the old class logits, which stabilizes the semantic topology during adaptation. Extensive experiments demonstrate the effectiveness and superiority of the proposed method.

ASRU: Activation Steering Meets Reinforcement Unlearning for Multimodal Large Language Models

Jiahui Guang, Haiyan Wang, Yingjie Zhu, Cuiyun Gao, Jing Li, Di Shao, Zhaoquan Gu

Multimodal large language models (MLLMs) may memorize sensitive cross-modal information during pretraining, making machine unlearning (MU) crucial. Existing met

hods typically evaluate unlearning effectiveness based on output deviations, whi le overlooking the generation quality after unlearning. This can easily lead to hallucinated or rigid responses, thereby affecting the usability and safety of t he unlearned model. To address this issue, we propose ASRU, a controllable multi modal unlearning framework that incorporates generation quality as a core evalua tion objective. ASRU first induces initial refusal behavior through activation r edirection, and then optimizes fine-grained refusal boundaries using a customize d reward function, thereby achieving a better trade-off between target knowledge unlearning and model utility. Experiments on Qwen3-VL show that ASRU significan tly improves unlearning effectiveness (+24.6%) on average and generation quality (5.8×) on average while effectively preserving model utility, using only a sma ll amount of retained supervision data.

Active Budget Allocation for Efficient Scaling Law Estimation via Surrogate-Guid ed Pruning
Viktoria Schram, Markus Hiller, Daniel Beck, Trevor Cohn
Predicting model performance at larger scales enables the design of training str ategies and architectures tailored to specific performance targets. Empirical sc aling law research identifies functional forms to aid this prediction task. Thes e describe the relationship between loss and compute using a loss-compute fronti er defined by learning curves. Due to the empirical nature of this approach, the computational burden is substantial, making strategic resource allocation essen tial -- yet it remains surprisingly underexplored.
In this work, we address this shortcoming by exploring the suitability of Succes sive Halving (SH) and SH combined with parametric and non-parametric surrogate m odels. In addition to enabling a more systematic allocation of a given compute b udget, our findings show that SH paired with surrogate models yields a set of le arning curves that includes one with a lower loss-compute value than what naive uniform allocation or an SH-only approach can obtain.
Our experiments demonstrate mean relative improvements of up to 2.84% and $5. 47\%$ on real-world and synthetic learning curve datasets.
This strategic resource allocation enables us to obtain accurate scaling laws at significantly reduced computational costs, saving up to 98.7% over the tradi tional exhaustive approach.
****

Reinforced Sequential Monte Carlo for Amortised Sampling
Sanghyeok Choi, Sarthak Mittal, Víctor Elvira, Jinkyoo Park, Esmeralda S. Whitam mer
This paper proposes a synergy of amortised and particle-based methods for sampli ng from distributions defined by unnormalised density functions. We state a conn ection between sequential Monte Carlo (SMC) and neural sequential samplers train ed by maximum-entropy reinforcement learning (MaxEnt RL), wherein learnt samplin g policies and value functions define proposal kernels and twist functions. Expl oiting this connection, we introduce an off-policy RL training procedure for the sampler that uses samples from SMC -- using the learnt sampler as a proposal -- as a behaviour policy that better explores the target distribution. We describe techniques for stable joint training of proposals and twist functions and an ad aptive weight tempering scheme to reduce training signal variance. Furthermore, building upon past attempts to use experience replay to guide the training of ne ural samplers, we derive a way to combine historical samples with annealed impor tance sampling weights within a replay buffer. On synthetic multi-modal targets (in both continuous and discrete spaces) and the Boltzmann distribution of alani ne dipeptide conformations, we demonstrate improvements in approximating the tru e distribution as well as training stability compared to both amortised and Mont e Carlo methods.

WarmServe: Enabling One-for-Many GPU Prewarming for Multi-LLM Serving
Chiheng Lou, Sheng Qi, Rui Kang, Yong Zhang, Chen Sun, pengcheng wang, Xuanzhe L iu, Xin Jin
Deploying multiple models within shared GPU clusters is a key strategy to improv

e resource efficiency in large language model (LLM) serving.
Existing multi-LLM serving systems improve GPU utilization at the cost
of degraded inference performance, particularly time-to-first-token (TTFT).
We attribute this degradation to the lack of awareness regarding future workload
 characteristics.
In contrast, recent analyses have shown the strong periodicity and long-term pre
dictability of real-world LLM serving workloads.
In this paper, we propose \textit{one-for-many GPU prewarming}, which proactivel
y loads parameters from multiple models onto GPUs based on workload forecasts.
These prewarmed weights enable the system to promptly instantiate serving instan
ces upon encountering request bursts.
We design and implement WarmServe, a multi-LLM serving system incorporating thre
e key techniques:
(1) a model placement algorithm that optimizes prewarming decisions to minimize
cross-model prewarming interference,
(2) a KV cache reservation strategy that repurposes idle KV cache space on runni
ng GPUs for prewarming new models,
and (3) an efficient GPU memory switching mechanism for tensor management.
Evaluation on real-world datasets shows that WarmServe reduces tail TTFT by up t
o 50.8$\times$ compared to the state-of-the-art autoscaling-based system,
while supporting up to 2.5$\times$ higher request throughput than the GPU-sharin
g system.

Self-CriTeach: LLM Self-Teaching and Self-Critiquing for Improving Robotic Plann
ing via Automated Domain Generation
Jinbang Huang, Zhiyuan Li, Yuanzhao Hu, Zhanguang Zhang, Mark Coates, Xingyue Qu
an, Yingxue Zhang
Large Language Models (LLMs) have recently shown strong promise for robotic task
 planning, particularly through automatic planning domain generation. However, p
rior approaches largely treat generated planning domains as planning utilities,
which are brittle under imperfect logical states and perception noise, overlooki
ng their potential as scalable sources of reasoning supervision and structured r
eward signals. At the same time, reasoning LLMs depend on chain-of-thought (CoT)
 supervision that is expensive to collect for robotic tasks, and reinforcement l
earning (RL) faces challenges on reward engineering. We propose Self-CriTeach, a
n LLM self-teaching and self-critiquing framework in which an LLM autonomously g
enerates symbolic planning domains that serve a dual role: (i) enabling large-sc
ale generation of robotic planning problem–plan pairs, and (ii) providing struct
ured reward functions. First, the self-written domains enable large-scale genera
tion of symbolic task plans, which are automatically transformed into extended C
oT trajectories for supervised fine-tuning. Second, the self-written domains are
 reused as structured reward functions, providing dense feedback for reinforceme
nt learning without manual reward engineering. This unified training pipeline yi
elds a planning-enhanced LLM with higher planning success rates, stronger cross-
task generalization, reduced inference cost, and resistance to imperfect logical
 states.

Fixed Budget is No Harder Than Fixed Confidence in Best-Arm Identification up to
 Logarithmic Factors
Kapilan Balagopalan, Yinan Li, Yao Zhao, Tuan Ngo Nguyen, Anton Daitche, Houssam
 Nassif, Kwang-Sung Jun
The best-arm identification (BAI) problem is one of the most fundamental problem
s in interactive machine learning, which has two flavors: the fixed-budget setti
ng (FB) and the fixed-confidence setting (FC). For K-armed bandits with a uni
que best arm, the optimal sample complexities for both settings have been settle
d down and they match up to logarithmic factors. This prompts an interesting re
search question about the generic, potentially structured BAI problems: is FB ha
rder than FC or the other way around? In this paper, we show that FB is no hard
er than FC up to logarithmic factors. We do this constructively: we propose a n
ovel algorithm called FC2FB (fixed confidence to fixed budget), which is a meta

algorithm that takes in an FC algorithm $\mathcal{A}$ and turn it into an FB alg orithm. We prove that FC2FB enjoys a sample complexity that matches, up to loga rithmic factors, that of the sample complexity of $\mathcal{A}$. This means tha t the optimal FC sample complexity is an upper bound of the optimal FB sample co mplexity up to logarithmic factors. Our result not only reveals a fundamental r elationship between FB and FC, but also has a significant implication: FC2FB com bined with existing state-of-the-art FC algorithms, leads to improved sample com plexity for a number of FB problems.

DEGAP: Dynamic Entropy-Guided Attention Perturbation for Contrastive Decoding in Large Vision-Language Models
Hyein Seo, Yuna Jeong, Mingyu Kang, Junhyeong Park, Yong Suk Choi
Large Vision–Language Models (LVLMs) have shown outstanding performance across v arious multimodal tasks, but they still suffer from hallucinations, where they g enerate incorrect information by relying on language priors without visual groun ding. To alleviate this issue, prior work has explored contrastive decoding appr oaches that compare the output of an original LVLM with that of a contrast branc h.
However, existing methods typically generate contrast logits through preprocessi ng of the input image. Such input-level perturbations fail to sufficiently refle ct the model’s internal degree of visual reliance during the decoding process.
To address this limitation, we propose Dynamic Entropy-Guided Attention Perturba tion (DEGAP) for contrastive decoding in LVLMs. DEGAP performs contrastive decod ing by directly perturbing visual attention and leveraging the resulting logits, without requiring any additional image preprocessing. To this end, we analyze t he layer-wise effects of visual attention perturbations and, based on these obse rvations, dynamically select the layers at which attention perturbation is appli ed according to the model’s confidence.
Experimental results on seven benchmarks demonstrate that DEGAP effectively miti gates various types of hallucinations and consistently outperforms state-of-the-art methods in general VQA performance.
****
LangForce: Bayesian Decomposition of Vision Language Action Models via Latent Ac tion Queries
Shijie Lian, Bin Yu, Xiaopeng LIN, Laurence Tianruo Yang, Zhaolong Shen, Changti Wu, YuZhuo Miao, Cong Huang, Kai Chen
Vision-Language-Action (VLA) models have shown promise in robot manipulation but often struggle to generalize to new instructions or complex multi-task scenario s. We identify a critical pathology in current training paradigms where goal-dri ven data collection creates a dataset bias. In such datasets, language instructi ons are highly predictable from visual observations alone, causing the condition al mutual information between instructions and actions to vanish, a phenomenon w e term Information Collapse. Consequently, models degenerate into vision-only po licies that ignore language constraints. To address this, we propose LangForce, enforces instruction following via Bayesian decomposition. By introducing learna ble Latent Action Queries, we construct a dual-branch architecture to estimate b oth a vision-only prior $p(a \mid v)$ and a language-conditioned posterior $\pi(a \mid v, \ell)$. We then optimize the policy to maximize the conditional Pointw ise Mutual Information (PMI) between actions and instructions. This objective ef fectively penalizes the vision shortcut and rewards actions that explicitly expl ain the language command. Extensive experiments across on three benchmarks demon strate substantial gains, including an 11.3\% improvement on the challenging OOD SimplerEnv benchmark, validating the ability of LangForce to robustly ground la nguage in action.

Semantic-Enriched Latent Visual Reasoning
Tianrun Xu, Yue Sun, Qixun Wang, Jingyi Lu, Yuan Wang, Tianren Zhang, Longteng G uo, Fengyun Rao, Jing LYU, Feng Chen, Jing Liu
Multimodal latent-space reasoning aims to replace explicit “thinking with images ” by performing visual reasoning directly in a compact latent space. However, ex

isting approaches largely rely on visual supervision and produce latent representations that lack sufficient semantic richness, limiting their ability to support diverse region-level reasoning tasks. In this work, we introduce \textbf{Semantic-Enriched Latent Visual Reasoning (SLVR)}, a two-stage learning framework that enriches latent representations with attribute-level visual semantics and aligns them with diverse reasoning objectives. In the first stage, SLVR learns semantically enriched region-centric latents under fine-grained attribute supervision. In the second stage, we design Multi-query Group Relative Policy Optimization (M-GRPO) to align latent representations across multiple queries grounded in the same region. To support this framework, we construct \textbf{SLV-Set}, comprising approximately 400K region-level attribute annotations and 800K multi-query question answering samples, and introduce \textbf{SV-QA}, a benchmark that evaluates latent reasoning under semantic variation. Experiments demonstrate that SLVR improves the robustness and semantic consistency of latent visual reasoning compared to existing baselines. Our code and datasets are available at \url{https://github.com/tinnel123666888/slvr}.

Transolver-3: Scaling Up Transformer Solvers to Industrial-Scale Geometries
Hang Zhou, Haixu Wu, Haonan Shangguan, Yuezhou Ma, Huikun Weng, Jianmin Wang, Mingsheng Long
Deep learning has emerged as a transformative tool for the neural surrogate modeling of partial differential equations (PDEs), known as neural PDE solvers. However, scaling these solvers to industrial-scale geometries with over 10^8 cells remains a fundamental challenge due to the prohibitive memory complexity of processing high-resolution meshes. We present Transolver-3, a new member of the Transolver family as a highly scalable framework designed for high-fidelity physics simulations. To bridge the gap between limited GPU capacity and the resolution requirements of complex engineering tasks, we introduce two key architectural optimizations:
faster slice and deslice by exploiting matrix multiplication associative property and geometry slice tiling to partition the computation of physical states.
Combined with an amortized training strategy by learning on random subsets of original high-resolution meshes and a physical state caching technique during inference, Transolver-3 enables high-fidelity field prediction on industrial-scale meshes. Extensive experiments demonstrate that Transolver-3 can handle meshes with over 160 million cells, achieving impressive performance across three challenging simulation benchmarks, including aircraft and automotive design tasks. Code is available at https://github.com/thuml/Transolver-3.

Hidden in Plain Sight -- Class Competition Focuses Attribution Maps
Nils Philipp Walter, Jilles Vreeken, Jonas Fischer
Attribution methods reveal which input features a neural network uses for a prediction, adding transparency to their decisions. A common problem is that these attributions seem unspecific, highlighting both important and irrelevant features. We revisit the common attribution pipeline and observe that using logits as attribution target is a main cause of this phenomenon. We show that the solution is in plain sight: considering distributions of attributions over multiple classes using existing attribution methods yields specific and fine-grained attributions. On common benchmarks, including the grid-pointing game and randomization-based sanity checks, this improves the ability of 18 attribution methods across 7 architectures up to $2\times$, agnostic to model architecture.

RLVE: Scaling Up Reinforcement Learning for Language Models with Adaptive Verifiable Environments
Zhiyuan Zeng, Hamish Ivison, Yiping Wang, Lifan Yuan, Shuyue Stella Li, Zhuorui Ye, Siting Li, Jacqueline He, Runlong Zhou, Tong Chen, Chenyang Zhao, Yulia Tsvetkov, Simon Shaolei Du, Natasha Jaques, Hao Peng, Pang Wei Koh, Hannaneh Hajishirzi
We introduce Reinforcement Learning (RL) with Adaptive Verifiable Environments (RLVE), an approach using verifiable environments that procedurally generate prob

lems and provide algorithmically verifiable rewards, to scale up RL for language models (LMs). RLVE enables each verifiable environment to dynamically adapt its problem difficulty distribution to the policy model's capabilities as training progresses. In contrast, static data distributions often lead to vanishing learning signals when problems are either too easy or too hard for the policy. To implement RLVE, we create RLVE-Gym, a large-scale suite of 400 verifiable environments carefully developed through manual environment engineering. Using RLVE-Gym, we show that environment scaling, i.e., expanding the collection of training environments, consistently improves generalizable reasoning capabilities. RLVE with joint training across all 400 environments in RLVE-Gym yields a 3.37% absolute average improvement across six reasoning benchmarks, starting from one of the strongest 1.5B reasoning LMs. By comparison, continuing this LM's original RL training yields only a 0.49% average absolute gain despite using over 3x more compute. We release our code publicly.
****

Anchored Decoding: Provably Reducing Copyright Risk for Any Language Model
Jacqueline He, Jonathan Hayase, Wen-tau Yih, Sewoong Oh, Luke Zettlemoyer, Pang Wei Koh

Language models (LMs) tend to memorize portions of their training data and reproduce verbatim spans. When the underlying sources are sensitive or copyright-protected, such reproduction raises issues of consent and compensation for creators and compliance risks for developers.

We propose Anchored Decoding, a plug-and-play inference-time method for suppressing verbatim reproduction: it enables decoding from any risky LM trained on mixed-license data by keeping generation in bounded proximity to a permissively trained safe LM.

Anchored Decoding does so by adaptively allocating a user-chosen information budget over the generation trajectory and enforcing per-step constraints that yield a sequence-level guarantee, enabling a tunable risk–utility trade-off.

To make Anchored Decoding practically useful, we introduce a new permissively trained safe model (TinyComma 1.8B), as well as Anchored-Byte Decoding, a byte-level variant of our method that enables cross-vocabulary fusion via the ByteSampler (Hayase et al., 2025) framework.

Across six model pairs on long-form metrics for copying risk and utility, Anchored and Anchored-Byte Decoding define a new Pareto frontier, preserving near-original fluency and factuality while eliminating up to 75\% of the measurable copying gap between the risky baseline and a safe reference, at a modest inference overhead.

CREDIT: Certified Ownership Verification of Deep Neural Networks Against Model Extraction Attacks
Bolin Shen, Zhan Cheng, Neil Zhenqiang Gong, Fan Yao, Yushun Dong

Machine Learning as a Service (MLaaS) has emerged as a widely adopted paradigm for providing access to deep neural network (DNN) models, enabling users to conveniently leverage these models through standardized APIs. However, such services are highly vulnerable to Model Extraction Attacks (MEAs), where an adversary repeatedly queries a target model to collect input-output pairs and uses them to train a surrogate model that closely replicates its functionality. While numerous defense strategies have been proposed, verifying the ownership of a suspicious model with strict theoretical guarantees remains a challenging task. To address this gap, we introduce CREDIT, a certified ownership verification against MEAs. Specifically, we employ mutual information to quantify the similarity between DNN models, propose a practical verification threshold, and provide rigorous theoretical guarantees for ownership verification based on this threshold. We extensively evaluate our approach on several mainstream datasets across different domains and tasks, achieving state-of-the-art performance. Our implementation is publicly available at: https://github.com/LabRAI/CREDIT.

FAIL: Flow Matching Adversarial Imitation Learning for Image Generation
Yeyao Ma, Chen Li, Xiaosong Zhang, Han Hu, Weidi Xie

Post-training of flow matching models—aligning the output distribution with a hi
gh-quality target—is mathematically equivalent to imitation learning. While Supe
rvised Fine-Tuning mimics expert demonstrations effectively, it cannot correct p
olicy drift in unseen states. Preference optimization methods address this but r
equire costly preference pairs or reward modeling. We propose Flow Matching Adve
rsarial Imitation Learning (FAIL), which minimizes policy-expert divergence thro
ugh adversarial training without explicit rewards or pairwise comparisons. We de
rive two algorithms: FAIL-PD exploits differentiable ODE solvers for low-varianc
e pathwise gradients, while FAIL-PG provides a black-box alternative for discret
e or computationally constrained settings. Fine-tuning FLUX with only 13,000 dem
onstrations from Nano Banana pro, FAIL achieves competitive performance on promp
t following and aesthetic benchmarks. Furthermore, the framework generalizes eff
ectively to discrete image and video generation, and functions as a robust regul
arizer to mitigate reward hacking in reward-based optimization.

Revealing Long-context Potential of Attention Heads via Frequency Kernels
Senyu Han, Yilu Cao, Kai Yu, Lu Chen
Large language model (LLM) exists a subset of attention heads that are highly re
sponsible for long-context processing. Existing work has identified different lo
ng-context heads in models, but their detection methods mainly rely on model inf
erence on actual long texts and do not analyze the inherent properties of the he
ad parameters. In this paper, we use kernel methods to analyze static \textit{fr
equency kernels} formed by different rotation frequency components of attention
heads, and we design a Long-context Potential Score (LPS) to measure the potenti
al of attention heads in processing long contexts. Kernels of heads with high LP
S exhibit concentrated low-frequency energy and low effective rank, which allow
them to effectively capture highly specialized information from distant contexts
. Experiments and analysis on long-context tasks and model behaviors show that t
he LPS metrics can well reflect the actual capability of heads on long contexts.

Furthermore, by simply amplifying low-frequency kernels of heads with high retri
eval potential, we can further improve model's performance on long-context tasks
. Our metrics and head enhancement methods are fully static and offline, and the
y can be quickly conducted under low-resource constraints. Code is publicly avai
lable at [here](https://github.com/OpenDFM/long-context-heads).

UniFast-HGR: Scalable and Efficient Maximal Correlation for Multimodal Models
Hongkang Zhang, Shao-Lun Huang, Yanlong Wang, Ercan Engin KURUOGLU
This paper presents UniFast-HGR, a scalable surrogate for Hirschfeld--Gebelein--
R\'enyi (HGR) maximal correlation in high-dimensional multimodal learning. The m
ethod replaces explicit covariance whitening with centered and ℓ_2-normaliz
ed cosine alignment, rewrites the covariance interaction in local-batch Gram spa
ce, and removes invariant diagonal self-correlation through Trivial Spectrum Sup
pression (TSS). This reformulation preserves the standardized dependence-maximiz
ation target of HGR-style learning while replacing the finite-sample whitening e
stimator with a differentiable local-batch objective whose dominant structural c
ost is $O(m^2K)$ for local batch size m and feature dimension K. OptFast-HGR
 further reduces the practical memory burden by estimating the off-diagonal stru
ctural term through stochastic projection. Experiments across retrieval, image c
lassification, remote sensing segmentation, and multimodal emotion recognition s
how consistent gains over covariance-based HGR/CCA variants and contrastive or n
eural MI-estimator objectives on strong multimodal backbones, while microbenchma
rks confirm stable behavior at extreme feature dimensions.

LiveOIBench: Can Large Language Models Outperform Human Contestants in Informati
cs Olympiads?
Kaijian Zou, Aaron Xiong, Yunxiang Zhang, Xinliang Frederick Zhang, Yueqi Ren, J
irong Yang, Ayoung Lee, Shitanshu Bhushan, Lu Wang
Competitive programming problems are increasingly used to evaluate the coding ca
pabilities of large language models (LLMs) due to their complexity and ease of v

erification.
Yet, current coding benchmarks face limitations such as a lack of exceptionally challenging problems, insufficient test case coverage, and reliance on online platform APIs that limit accessibility.
To address these issues, we introduce LiveOIBench, a large-scale competitive programming benchmark featuring 403 expert-curated problems, averaging 60 official test cases each, drawn from 72 contests across 14 Informatics Olympiads held between 2023 and 2025.
LiveOIBench has four key features:
(1) expert-designed tasks with detailed subtask rubrics and extensive test cases;
(2) direct comparison to elite human contestants;
(3) continuous updates to reduce contamination risk; and
(4) a fully offline, reproducible evaluation system.
Benchmarking 34 popular general-purpose and reasoning LLMs, we find that GPT-5 achieves an 81.76th percentile, still falling short of top human contestants, while among the open-weight models, GPT-OSS-120B reaches only the 60th percentile.
Reasoning-trace analyses indicate that robust reasoning models prioritize precise problem analysis over excessive exploration.
Finally, analyses across release dates, task familiarity, and code similarity find minimal evidence of data contamination in our benchmark.
Our leaderboard, code, and data are available at: https://liveoibench.github.io/.

On Structured State-Space Duality
Jerry Yao-Chieh Hu, Xiwen Zhang, Ali ElSheikh, Weimin Wu, Han Liu
Structured State-Space Duality (SSD) [Dao \& Gu, ICML 2024] is an equivalence between a simple Structured State-Space Model (SSM) and a masked attention mechanism.
In particular, a state-space model with a scalar-times-identity state matrix is equivalent to a masked self-attention with a 1-semiseparable causal mask.
Consequently, the same sequence transformation (model) has two algorithmic realizations:
as a linear-time $O(T)$ recurrence or as a quadratic-time $O(T^2)$ attention.
In this note, we formalize and generalize this duality:
(i)
we extend SSD from the scalar■identity case to general diagonal SSMs (diagonal state matrices);
(ii) we show that these diagonal SSMs match the scalar case's training complexity lower bounds while supporting richer dynamics;
(iii) we establish a necessary and sufficient condition under which an SSM is equivalent to 1-semiseparable masked attention;
and
(iv) we show that such duality fails to extend to standard softmax attention due to rank explosion.
Together, these results tighten the bridge between recurrent SSMs and Transformers, and widen the design space for expressive yet efficient sequence models.
Code is available at https://github.com/MAGICS-LAB/state_space_daulity.
****
FlexRank: Nested Low-Rank Knowledge Decomposition for Adaptive Model Deployment
Riccardo Zaccone, Stefanos Laskaridis, Marco Ciccone, Samuel Horváth
The growing scale of deep neural networks, encompassing large language models (LLMs) and vision transformers (ViTs), has made training from scratch prohibitively expensive and deployment increasingly costly.
These models are often used as computational monoliths with fixed cost, hindering adaptive deployment across different cost budgets.
We argue that nested components, ordered by importance, can be extracted from pretrained models and selectively activated within the available computational budget. To this end, our proposed FlexRank method leverages low-rank weight decompo

sition with nested, importance-based consolidation to extract submodels of increasing capabilities. Our approach enables a _``train-once, deploy-everywhere''_ paradigm offering a graceful trade-off between cost and performance without training from scratch for each budget - advancing practical deployment of large models.

Conflict-Aware Additive Guidance for Flow Models under Compositional Rewards
Xuehui Yu, Fucheng Cai, WANG MEIYI, Xiaopeng Fan, Harold Soh
Inference-time guided sampling steers state-of-the-art diffusion and flow models without fine-tuning by interpreting the generation process as a controllable trajectory. This provides a simple and flexible way to inject external constraints (e.g., cost functions or pre-trained verifiers) for controlled generation. However, existing methods often fail when composing multiple constraints simultaneously, which leads to deviations from the true data manifold. In this work, we identify root causes of this off-manifold drift and find that the approximation error scales severely with gradient misalignment. Building on these findings, we propose Conflict-Aware Additive Guidance (g^car), a lightweight and learnable method, which actively rectifies off-manifold drift by dynamically detecting and resolving gradient conflicts. We validate g^car across diverse domains, ranging from synthetic datasets and image editing to generative decision-making for planning and control. Our results demonstrate that g^car effectively rectifies off-manifold drift, surpassing baselines in generation fidelity while using light compute. Code is available at <https://github.com/yuxuehui/CAR-guidance>.

Global Policy-Space Response Oracles for Two-Player Zero-Sum Games
Junyu Zhang, Feihong Yang, Jian Wang, Chao Wang, Xudong Zhang
The Policy-Space Response Oracles (PSRO) framework scales equilibrium computation to large zero-sum games by iteratively expanding a restricted strategy set using deep reinforcement learning (DRL). A central challenge is to construct, under limited computational budgets, a small strategy population whose induced game well approximates the full game. Existing PSRO variants typically expand the population using best responses to meta-strategies computed from restricted-game payoffs, which can lead to inefficient expansions that provide limited global improvement. We propose to guide population expansion by directly evaluating the post-expansion population quality. Specifically, we adopt Population Exploitability (PE) to measure how well a restricted strategy set represents the full game, and introduce a two-phase exploration--selection framework that explicitly minimizes PE during expansion. We instantiate this framework as Global PSRO, a practical DRL-based algorithm that efficiently generates candidate responses and estimates PE via parameter-sharing conditional neural networks. Experiments across multiple two-player zero-sum games show that Global PSRO achieves lower exploitability and approximates Nash equilibria with significantly fewer policy iterations than prior PSRO methods. The experimental code is available at https://github.com/Zhangjy1997/GlobalPSRO.

Optimal Transport Group Counterfactual Explanations
Enrique Valero-Leal, Bernd Bischl, Pedro Larrañaga, Concha Bielza, Giuseppe Casalicchio
Group counterfactual explanations find a set of counterfactual instances to explain a group of input instances contrastively. However, existing methods either (i) optimize counterfactuals only for a fixed group and do not generalize to new group members, (ii) strictly rely on strong model assumptions (e.g., linearity) for tractability and/or (iii) poorly control the counterfactual group geometry distortion. We instead learn an explicit optimal transport map that sends any group instance to its counterfactual without re-optimization, minimizing the group's total transport cost. This enables generalization with fewer parameters, making it easier to interpret the common actionable recourse. For linear classifiers, we prove that functions representing group counterfactuals are derived via mathematical optimization, identifying the underlying convex optimization type (QP,

QCQP, ...). Experiments show that they accurately generalize, preserve group geometry and incur only negligible additional transport cost compared to baseline methods. If model linearity cannot be exploited, our approach also significantly outperforms the baselines.

Geometry-Aware Contrastive Learning for Few-Shot Automatic Modulation Recognition

guanqun zhao, Liu Yitong, Jiaxuan Fang, Yufei Mao, Hongwen Yang

Standard Self-Supervised Learning (SSL) for Automatic Modulation Recognition (AMR) struggles with ineffective isotropic augmentations, spectral instability, and semantic drift. To address these challenges, we propose Dynamic-Consistency Contrastive Learning (DyCo-CL), a geometry-aware framework that couples Virtual Adversarial Augmentation (VAA) with a semantic consistency loss. We provide a theoretical analysis indicating that this strategy acts as an implicit spectral regularizer for the encoder, enabling stable manifold exploration. Complementing this, our Signal-Adaptive Swin Backbone with fixed-window attention improves structural stability by constraining attention locality, while a Hybrid Knowledge Fusion module anchors representations with physical priors. Experiments on RML benchmarks show that DyCo-CL achieves a 6.27% accuracy gain in 1-shot settings over prior methods.

PISA: Privacy-Preserving Split Adaptation with Model IP Protection

Haocheng Yang, Xiang Cheng, ZONGDA HAN, Pengjie Wang, Changkang Chi, Pengfei Zhang, Sen Su

Fine-tuning Large Language Models (LLMs) enables data holders to construct proprietary, task-specific models by leveraging external high-performance computing infrastructure.

However, existing paradigms typically address data privacy and model intellectual property (IP) in isolation, failing to simultaneously uphold both constraints. Privacy-prioritized methods compromise model IP by hosting parameters remotely, while IP-oriented collaborative schemes relying on end-to-end gradient flows inherently violate strict data privacy standards. To address these challenges, we present **PISA** (**P**rivacy-preserving and **I**P-protected **S**plit **A**daptation), a split fine-tuning framework designed to preserve both data privacy and model IP while maintaining high utility.

In PISA, we propose three methods: a Manifold Rectification Pre-training (MRP) method to equip the server-side model with intrinsic robustness against privacy-induced distribution shifts; a Dual-Stream Semantic Compensation (DSC) method to recover feature utility using local clean data as priors; and a Utility-Aware Gradient Rectification (UGR) method to adaptively maximize the performance of the parameter-constrained local model. Experiments on GLUE show that PISA ensures dual protection and delivers a substantial 23.0\% performance gain over the privacy-prioritized baseline under strict privacy budgets.

Revisiting Spectral Representations in Generative Diffusion Models

Yuehao Wang, Peihao Wang, Hanwen Jiang, Ziyi Yang, Qixing Huang, Zhangyang Wang

Diffusion models have shown remarkable performance on diverse generation tasks. Recent work finds that imposing representation alignment on the hidden states of diffusion networks can both facilitate training convergence and enhance sampling quality, yet the mechanism driving this synergy remains insufficiently understood. In this paper, we investigate the connection between self-supervised spectral representation learning and diffusion generative models through a shared perspective on perturbation kernels. On the diffusion side, samples (e.g., images, videos) are produced by reversing a stochastic noise-injection process specified by Gaussian kernels; on the spectral representation side, spectral embeddings emerge from contrasting positive and negative relations induced by random perturbation kernels. Motivated by this, we propose a self-supervised spectral representation alignment method to facilitate diffusion model training. In addition, we clarify how joint spectral learning can benefit diffusion training from a geometric perspective. Furthermore, we find that the optimization of the spectral align

ment objective is in an equivalent form of diffusion score distillation in the r
epresentation space. Building on these findings, we integrate a spectral regular
izer into diffusion training objectives to improve the performance of diffusion
models on multiple datasets. Experiments across images and 3D point clouds show
consistent gains in generation quality.

Least-Loaded Expert Parallelism: Load Balancing An Imbalanced Mixture-of-Experts
Xuan-Phi Nguyen, Shrey Pandit, Austin Xu, Caiming Xiong, Shafiq Joty
Mixture-of-Experts (MoE) models are typically pre-trained with explicit load-bal
ancing constraints to ensure statistically balanced expert routing. Despite this
, we observe that even well-trained MoE models exhibit significantly imbalanced
routing. This behavior is arguably natural—and even desirable—as imbalanced rout
ing allows models to concentrate domain-specific knowledge within a subset of ex
perts. Expert parallelism (EP) is designed to scale MoE models by distributing e
xperts across multiple devices, but with a less-discussed assumption of balanced
 routing. Under extreme imbalance, EP can funnel a disproportionate number of to
kens to a small number of experts, leading to compute- and memory-bound failures
 on overloaded devices during post-training or inference, where explicit load ba
lancing is often inapplicable. We propose Least-Loaded Expert Parallelism (LLEP)
, a novel EP algorithm that dynamically reroutes excess tokens and associated ex
pert parameters from overloaded devices to underutilized ones. This ensures that
 all devices complete their workloads within the minimum collective latency whil
e respecting memory constraints. Across different model scales, LLEP achieves up
 to 5x speedup and 4x reduction in peak memory usage compared to standard EP. Th
is enables faster and higher-throughput post-training and inference, with ~1.9x
faster for gpt-oss-120b. We support our method with extensive theoretical analys
is and comprehensive empirical evaluations, including ablation studies. These re
sults illuminate key trade-offs and enable a principled framework for hardware-s
pecific hyper-parameter tuning to achieve optimal performance.

Hierarchical Reinforcement Learning for Sparse-Reward Search in Commutative Alge
bra
Giorgi Butbaia, Paul Orland, Coco Huang, Davide Passaro, Lucas Fagan, Michele Ta
rquini, Hailong Dao, David Eisenbud, Ali Shehper, Sergei Gukov
Applying machine learning techniques to solving long-standing mathematical conje
ctures can be particularly challenging due to their extreme reward sparsity. As
an illustrative example, we consider Kalai's algebraic Hirsch conjecture and rec
ast the construction of its counterexamples as a sparse-reward reinforcement lea
rning problem on graphs. We propose a constrained options-based HRL framework wi
th an equivariant graph neural network policy, which allows us to learn useful t
emporal abstractions for this task. We evaluate our approach over a wide range o
f degrees and demonstrate that it consistently outperforms classical RL algorith
ms as well as greedy search. By exploiting the hierarchical structure of the pro
blem, we effectively provide a first-of-its-kind application of HRL to a problem
 in commutative algebra.
****

Capacity-Aware Mixture Law Enables Efficient LLM Data Optimization
Jingwei Li, Xinran Gu, Jingzhao Zhang
A data mixture refers to how different data sources are combined to train large
language models, and selecting an effective mixture is crucial for optimal downs
tream performance. Existing methods either conduct costly searches directly on t
he target model or rely on mixture scaling laws that fail to extrapolate well to
 large model sizes.
We address these limitations by introducing a compute-efficient pipeline for dat
a mixture scaling. First, we propose CAMEL, a capacity-aware mixture law that mo
dels validation loss with the nonlinear interplay between model size and mixture
. We also introduce a loss-to-benchmark prediction law that estimates benchmark
accuracy from validation loss, enabling end-to-end performance prediction for th
e target model. Next, we study how to allocate a fixed compute budget across mod
el scales to fit the law and reduce prediction error. Finally, we apply our meth

od to Mixture-of-Experts models with up to 7B-A150M parameters to fit the law, a
nd verify the optimal mixture derived from the law by extrapolating to a 55B-A1.
2B target model. Compared to prior methods, we reduce mixture optimization costs
 by 50\% and improves downstream benchmark performance by up to 3\%.

PrivCode++: Latent-Conditioned Differentially Private Code Generation for Compre
hensive Guarantees

Zheng Liu, Chen GONG, Terry Yue Zhuo, Zhou Yang, Kecen Li, Wenlong Meng, Xinwen
Hou, Yu Liu, Xiaochen Li

Large language models fine-tuned on instruction–code pairs may memorize and subs
equently leak sensitive training data. Existing differentially private (DP) code
 generation methods primarily protect code snippets while assuming prompts are p
ublic, which fails in realistic scenarios where prompts may also contain sensiti
ve information. When prompts cannot be explicitly learned or used during generat
ion, code synthesis suffers from severe utility degradation as well as reduced d
iversity and fidelity. To address these challenges, we propose PrivCode++, the f
irst work to explore DP code generation where both prompts and code snippets are
 considered sensitive in LLM fine-tuning. PrivCode++ introduces a two-stage DP f
ramework with a Privacy-Free Latent Conditioning module, enabling effective DP f
ine-tuning and data synthesis without direct access to sensitive prompts or code
. Extensive experiments show that PrivCode++ achieves substantially higher utili
ty than baselines, remains competitive with the method with relaxing privacy ass
umptions, and provides stronger privacy guarantees.

Tensor Train Diffusion: Leveraging Low-Rank Structures for High-Dimensional Scor
e-Based Sampling

Robert Gruhlke, Julius Berner, David Sommer, Lorenz Richter

Diffusion models offer a powerful framework for sampling from complex probabilit
y densities by learning to reverse a noising process. A common approach involves
 solving for the time-reversed stochastic differential equation (SDE), which req
uires the score function of the evolving sample distribution. The logarithm of t
his distribution's density is governed by a Hamilton-Jacobi-Bellman (HJB) type p
artial differential equation (PDE). However, current methods for solving this PD
E, such as PINNs or trajectory-based techniques, often suffer from long training
 times and significant sensitivity to hyperparameter tuning. In this work, we in
troduce a novel and efficient solver for the underlying HJB equation based on th
e functional tensor train (FTT) format. The FTT representation leverages latent
low-rank structures to efficiently approximate high-dimensional functions, enabl
ing both model compression and rapid computation. By integrating this efficient
representation with a backward-in-time iterative scheme derived from backward st
ochastic differential equations (BSDEs), we develop a fast, robust and accurate
sampling method. Our approach overcomes primary bottlenecks of existing techniqu
es, enabling high-fidelity sampling from challenging target distributions with i
mproved efficiency.

Trajectory Seriation via Spectral Tangent Alignment and Global Embedding

Zhixin Zhou, Navin Souda, Arash A. Amini

We study linear seriation from noisy point clouds: given samples from an unknown
 one-dimensional curve embedded in $\mathbb{R}^d$, recover their latent order al
ong the curve, up to reversal. Unlike much of the seriation literature, which st
arts from a precomputed similarity matrix, this setting retains ambient coordina
tes and therefore local geometric information. We propose STAGE, a geometric ord
ering method that estimates local tangent directions by neighborhood PCA, resolv
es their sign ambiguity through a graph-wide $\mathbb{Z}_2$ synchronization step
, and constructs signed local displacement estimates by projecting ambient diffe
rences onto the oriented tangents. These increments are then integrated into a g
lobal scalar embedding through an inhomogeneous least-squares problem, equivalen
tly a Laplacian linear system with a nonzero right-hand side, and the final orde
r is obtained by sorting the embedding. We prove a finite-sample Kendall's $\tau
$ recovery bound that makes explicit the roles of curvature, noise, neighborhood

scale, sampling density, and graph connectivity. Empirically, STAGE gives accurate and fast order recovery on high-dimensional synthetic curves, compares favorably with spectral seriation, 1D UMAP, 1D t-SNE, Recanati's method, LTSA, and SABRE, and produces meaningful pseudotime orderings on single-cell RNA-seq datasets.

DiP-G: Discrete Prompting for Graph Neural Networks

Yumeng Zhao, Huiying Hu, Shuo Wen, Junjie Shen, Bei Hua

Graph Neural Networks (GNNs) are increasingly adopting the "pre-training, adaptation" paradigm, which first pre-train GNNs on large-scale unlabeled graph data and then adapt them to specific downstream tasks. As a common pattern, graph prompting adapts to the frozen encoder by modifying the input graph structure, rather than fine-tuning the model parameters. However, most existing graph prompting approaches optimize the continuous and weighted adjacency structure in the adaptation phase, while requiring a hard discretization at inference time. This difference causes a train-test mismatch which is particularly harmful in few-shot regimes. To address the issue, we propose **Di**screte **P**rompting for **G**raphs, a discrete prompting framework that directly learns task-specific topology prompts in the combinatorial space. DiP-G operates on multi-hop local candidate subgraphs to ensure scalability, generates hard (k)-sparse prompts through a perturbed Top-(k) solver, and optimizes the discrete structures using an I-MLE gradient estimator. To improve the efficiency of backward pass, we further introduce an adaptive active-set screening rule that accelerates the target solve and can provably maintain the accuracy of the solution. Extensive experiments conducted on multiple benchmark datasets have validated the effectiveness of our proposed method.

Detecting the Semantic Fixed Point: A Geometric Framework for Efficient Inference

Jiawei Gu, Ziyue Qiao, Xiao Luo

Each layer of a Transformer refines the hidden state toward a prediction, an iterative process resembling fixed-point iteration. Yet when should this iteration terminate? Existing early exit methods rely on output confidence as a proxy for internal convergence. We take a more direct approach by examining the geometry of the hidden state trajectory. We find that layer-wise updates exhibit a two-phase structure: large, volatile updates in early layers, followed by small, aligned updates as the model propagates an already-formed representation. The transition is remarkably sharp. This yields a simple criterion: exit when step size vanishes and direction stabilizes. We track the normalized update norm and cosine similarity between consecutive updates, exiting when both indicate convergence. The overhead is $O(d)$ per layer, independent of vocabulary size, requiring no learned components or architectural modifications. On LLaMA-2-7B and LLaMA-2-13B across question answering and commonsense reasoning tasks, this geometric criterion reduces FLOPs by 30--35\% while retaining over 98\% of full-depth accuracy.

Knowing Bias, Doing Better: Mitigating Social Bias in LLMs via Know-Bias Neuron Enhancement

Jinhao Pan, Chahat Raj, Anjishnu Mukherjee, Sina Mansouri, Bowen Wei, Shloka Yada, Ziwei Zhu

Large language models (LLMs) exhibit social biases that reinforce harmful stereotypes, limiting their safe deployment. Most existing debiasing methods adopt a suppressive paradigm by modifying parameters, prompts, or neurons associated with biased behavior; however, such approaches are often brittle, weakly generalizable, data-inefficient, and prone to degrading general capability. We propose \textbf{KnowBias}, a lightweight and conceptually distinct framework that mitigates bias by strengthening, rather than suppressing, neurons encoding bias-knowledge. KnowBias identifies neurons encoding bias knowledge using a small set of bias-knowledge questions via attribution-based analysis, and selectively enhances them at inference time. This design enables strong debiasing while preserving general capabilities, generalizes across bias types and demographics, and is highly da

ta efficient, requiring only a handful of simple yes/no questions and no retrain ing. Experiments across multiple benchmarks and LLMs demonstrate consistent stat e-of-the-art debiasing performance with minimal utility degradation. Data and co de are available at \url{https://github.com/JP-25/KnowBias}.

Mixture of Distributions Matters: Dynamic Sparse Attention for Efficient Video D iffusion Transformers
Yuxi Liu, Yipeng Hu, Zekun Zhang, Kunze Jiang, Kun Yuan
While Diffusion Transformers (DiTs) have achieved notable progress in video gene ration, this long-sequence generation task remains constrained by the quadratic complexity inherent to self-attention mechanisms, creating significant barriers to practical deployment. Although sparse attention methods attempt to address th is challenge, existing approaches either rely on oversimplified static patterns or require computationally expensive sampling operations to achieve dynamic spar sity, resulting in inaccurate pattern predictions and degraded generation qualit y. To overcome these limitations, we propose a \underline{\textbf{M}}ixture-\und erline{\textbf{O}}f-\underline{\textbf{D}}istribution \textbf{DiT} (\textbf{MOD-DiT}), a novel sampling-free dynamic attention framework that accurately models evolving attention patterns through a two-stage process. First, MOD-DiT leverage s prior information from early denoising steps and adopts a {distributed mixing approach} to model an efficient linear approximation model, which is then used t o predict mask patterns for a specific denoising interval. Second, an online blo ck masking strategy dynamically applies these predicted masks while maintaining historical sparsity information, eliminating the need for repetitive sampling op erations. Extensive evaluations demonstrate consistent acceleration and quality improvements across multiple benchmarks and model architectures, validating MOD-DiT's effectiveness for efficient, high-quality video generation while overcomin g the computational limitations of traditional sparse attention approaches.
****

TokenDrop: Token-Level Importance-Aware Backward Propagation Skipping for Effici ent LLM Fine-Tuning
Beomseok Kim, Sol Namkung, Dongsuk Jeon
Despite the success of parameter-efficient fine-tuning (PEFT) methods in reducin g parameter-related overhead, fine-tuning large language models (LLMs) is still bottlenecked by significant memory and computational demands. In this paper, we propose **TokenDrop**, a token-level importance-aware backpropagation skipping m ethod that reduces activation memory and accelerates LLM fine-tuning by skipping backward computations for less informative tokens. TokenDrop evaluates token im portance based on the magnitude of residual updates during the forward pass, ena bling lightweight, gradient-free importance estimation. Furthermore, we introduc e cumulative token selection to preserve gradient continuity across layers and l azy selection scheduling that defers token selection to facilitate globally info rmed importance scoring under memory constraints. Across a range of experiments, TokenDrop achieves up to **42.9**\% reduction in memory usage and up to **1.50* *$\times$ training speedup, while preserving accuracy and outperforming existing backpropagation-skipping baselines. The code is available at https://github.com /kimbss470/tokendrop_official.
****

PuzzleMoE: Efficient Compression of Large Mixture-of-Experts Models via Sparse E xpert Merging and Bit-packed inference
Yushu Zhao, Zheng Wang, Minjia Zhang
Mixture-of-Experts (MoE) have shown strong potential in scaling language models efficiently by activating only a small subset of experts per input. However, the ir deployment remains limited due to the high memory overhead associated with st oring all expert parameters, particularly as the number of experts increases. To address this challenge, prior works have explored expert dropping and merging s trategies; however, they often suffer from notable performance drop especially a t high compression ratios due to their reliance on coarse-grained tensor- or exp ert-level operations. In this paper, we introduce PuzzleMoE, the first MoE mergi ng method to enable fine-grained element-wise merging while achieving both high

accuracy and inference speed, via two key innovations: First, PuzzleMoE performs sparse expert merging by identifying element-wise weight redundancy and specialization. It introduces a dual-mask approach to capture both shared and expert-specific salient parameters. Second, to avoid the overhead of storing masks and signs, we introduce a bit-packed encoding scheme that reuses underutilized exponent bits, enabling efficient MoE inference on GPUs. Extensive experiments demonstrate that PuzzleMoE outperforms prior MoE compression methods by up to 16.7\% on MMLU at 50\% compression ratio, and achieves up to 1.80$\times$ end-to-end inference throughput gain.

Find, Fix, Reason: Context Repair for Video Reasoning
Haojian Huang, Chuanyu Qin, Yinchuan Li, Ying-Cong Chen
Reinforcement learning has advanced video reasoning in large multi-modal models, yet dominant pipelines either rely on on-policy self-exploration, which plateaus at the model's knowledge boundary, or hybrid replay that mixes policies and demands careful regularization. Dynamic context methods zoom into focused evidence but often require curated pretraining and two-stage tuning, and their context remains bounded by a small model's capability. In contrast, larger models excel at instruction following and multi-modal understanding, can supply richer context to smaller models, and rapidly zoom in on target regions via simple tools. Building on this capability, we introduce an observation-level intervention: a frozen, tool-integrated teacher identifies the missing spatiotemporal dependency and provides a minimal evidence patch (e.g., timestamps, regions etc.) from the original video while the question remains unchanged. The student answers again with the added context, and training updates with a chosen-rollout scheme integrated into Group Relative Policy Optimization (GRPO). We further propose a Robust Improvement Reward (RIR) that aligns optimization with two goals: outcome validity through correct answers and dependency alignment through rationales that reflect the cited evidence. Advantages are group-normalized across the batch, preserving on-policy exploration while directing it along causally meaningful directions with minimal changes to the training stack. Experiments on various related benchmarks show consistent accuracy gains and strong generalization. Project page is available at https://jethrojames.github.io/FFR/.

Multi-Scale Wavelet Transformers for Operator Learning of Dynamical Systems
Xuesong Wang, Michael Groom, Rafael Oliveira, He Zhao, Terence O'kane, Edwin V. Bonilla
Recent years have seen a surge in data-driven surrogates for dynamical systems that can be orders of magnitude faster than numerical solvers. However, many machine learning-based models such as neural operators exhibit spectral bias, attenuating high-frequency components that often encode small-scale structure. This limitation is particularly damaging in applications such as weather forecasting, where misrepresented high frequencies can induce long-horizon instability. To address this issue, we propose multi-scale wavelet transformers (MSWTs), which learn system dynamics in a tokenized wavelet domain. The wavelet transform explicitly separates low- and high-frequency content across scales. MSWTs leverage a wavelet-preserving downsampling scheme that retains high-frequency features and employ wavelet-based attention to capture dependencies across scales and frequency bands. Experiments on chaotic dynamical systems show substantial error reductions and improved long-horizon spectral fidelity. On the ERA5 climate reanalysis, MSWTs further reduce climatological bias, demonstrating their effectiveness in a real-world forecasting setting.
****

The Loss Is Not Enough: Sampling Conditions and Inductive Bias in Contrastive Representation Learning
Justinas Zaliaduonis, Patrick Putzky, Till Richter, Sergios Gatidis
Contrastive learning has become a leading paradigm for self-supervised representation learning, yet the conditions under which it recovers meaningful latent geometry remain incompletely understood. We develop a measure-theoretic framework formalizing the diversity condition, a support requirement on positive-pair sampl

ing that is necessary for isometric latent recovery. We show that in the standar d full-support von Mises-Fisher setting implies the satisfaction of the diversit y condition and global minimizers recover latent geometry up to orthogonal trans formation, while restricted conditionals can make non-orthogonal maps attain str ictly lower asymptotic contrastive loss. We introduce a support-corrected Inform ation Noise Contrastive Estimation (InfoNCE) variant as a theoretical fix: this correction makes orthogonal latent space recovery achievable but does not unique ly select it. Experiments on synthetic benchmarks validate the identifiability p redictions, and CIFAR-10 experiments are consistent with the qualitative predict ion that architectural inductive bias becomes more important when sampling diver sity is limited. Together, our results clarify how sampling mechanisms and encod er inductive bias interact in contrastive representation learning.

Multi-task Linear Regression without Eigenvalue Lower Bounds: Adaptivity, Robust ness, and Safety
Seok-Jin Kim
We study the multi-task linear regression problem in the presence of contaminate d tasks.
We address the setting where the unknown parameters of a majority of tasks are c lose in the ℓ_2-norm, while a fraction of tasks are arbitrary outliers.
Existing theoretical frameworks for this problem rely heavily on the assumption that the empirical second moment of each task has a minimum eigenvalue bounded a way from zero (order $\Omega(1)$).
Crucially, this assumption fails in many high-dimensional scenarios, rendering p rior guarantees vacuous.
To overcome this limitation, we propose an estimator based on matrix-weighted no rm regularization.
We also introduce a relative balancedness condition, quantified by a balancednes s constant, that compares each task's second moment with the average inlier geom etry and relaxes the need for taskwise second-moment lower bounds.
In favorable regimes with moderate balancedness, our prediction MSE bounds match the rate of Duan and Wang (2023) under substantially weaker spectral assumption s; the resulting task-overall MSE is minimax optimal up to logarithmic factors.
Furthermore, we demonstrate that our estimator enjoys a safety guarantee: when t he relevant balancedness constant is large or infinite, or when tasks are unrela ted, the method performs no worse than independent task learning.

ParaTool: Shifting Tool Representations from Context to Parameters
Zekai Yu, Qi Meng, Qizhi Chu, Yu Hao, Chuan Shi, Cheng Yang
Tool calling extends large language models (LLMs) by enabling grounded interacti on with external executable interfaces, thereby supporting environment-coupled p roblem solving. However, mainstream in-context learning (ICL) approaches typical ly incorporate detailed tool documentation and usage examples directly into the context. This results in substantial inference overhead and heightened risks of hallucination as the context length grows. Conversely, while tuning-based method s improve general tool-calling capabilities, they often fail to effectively inte rnalize the specific details of previously seen tools, thereby retaining a depen dency on in-context documentation. To address these limitations, we propose Para Tool, a framework that projects each tool into a dedicated, loadable set of para meters. By equipping a dynamic integration of these parameterized tools, the LLM can perform tool calling without relying on in-context documents or examples. S pecifically, our approach consists of three stages: (1) parametric tool pre-trai ning encapsulates the knowledge of different tools into independent parameter mo dules; (2) soft tool selection employs a gating network to dynamically weigh and aggregate relevant tool parameters; and (3) parametric tool fine-tuning jointly updates tool parameters to align the training and inference processes. Experime nts on Stable ToolBench and BFCL demonstrate that ParaTool significantly outperf orms strong ICL-based baselines, achieving superior performance while reducing c omputational complexity.

Understanding and Mitigating Token-Pruning-Induced Vulnerabilities in VLMs
Shuailong Wang, Xinyu Lyu, Shengming Yuan, Jingkuan Song, Heng Tao Shen, Lianli Gao
Token-Pruning accelerates Vision-Language Models by removing redundant visual tokens, yet its safety implications remain underexplored. In this work, we present the first comprehensive safety evaluation of Token-Pruning mechanisms and find that: most pruning strategies significantly degrade safety as pruning ratios increase, whereas Query-based Compression shows the opposite, with extreme pruning (up to 99.8%), unexpectedly improves model safety. This sharp contrast prompts a key question: How do different Token-Pruning strategies reshape model safety behavior, and is it possible to enhance safety without sacrificing acceleration? To answer this, we identify an unrecognized mechanism, termed Pruning-Induced Malicious Amplification, where removal of background tokens triggers a side effect: forcing the model's attention to collapse onto a few retained malicious anchors within the foreground, inadvertently amplifying their toxic semantics under jailbreak. To address that, we propose an inference-time and plug-and-play Safety-Aware Pruning (SAP) mechanism that counteracts such dominance via three steps: (1) identifying malicious anchors, (2) restoring pruned benign tokens, and (3) reallocating excessive attention from malicious anchors to benign tokens. Extensive experiments across three safety and four utility benchmarks demonstrate that SAP mitigates pruning-induced vulnerabilities, i.e., reducing ASR by up to 62%, without compromising efficiency or utility.

Can Microcanonical Langevin Dynamics Leverage Mini-Batch Gradient Noise?
Emanuel Sommer, Kangning Diao, Jakob Robnik, Uros Seljak, David Rügamer
Scaling inference methods such as Markov chain Monte Carlo to high-dimensional models remains a central challenge in Bayesian deep learning. A promising recent proposal, microcanonical Langevin Monte Carlo, has shown state-of-the-art performance across a wide range of problems. However, its reliance on full-dataset gradients makes it prohibitively expensive for large-scale problems. This paper addresses a fundamental question: Can microcanonical dynamics effectively leverage mini-batch gradient noise? We provide the first systematic study of this problem, establishing a novel continuous-time theoretical analysis of stochastic-gradient microcanonical dynamics. We reveal two critical failure modes: a theoretically derived bias due to anisotropic gradient noise and numerical instabilities in complex high-dimensional posteriors. To tackle these issues, we propose a principled gradient noise preconditioning scheme shown to significantly reduce this bias and develop a novel, energy-variance-based adaptive tuner that automates step size selection and dynamically informs numerical guardrails. The resulting algorithm is a robust and scalable microcanonical Monte Carlo sampler that achieves state-of-the-art performance on challenging high-dimensional inference tasks like Bayesian neural networks. Combined with recent ensemble techniques, our work unlocks a new class of stochastic microcanonical Langevin ensemble (SMILE) samplers for large-scale Bayesian inference.
****
SCHUR-A*: Layer-wise Optimal Expert Pruning for MoEs via Schur-Complement Guided A* Search
Zheng Chen, Yang Weifeng, Jianxiao Tang, Buhui Yao
Sparse Mixture-of-Experts (MoE) language models enable conditional computation but face deployment challenges due to the memory wall: while few experts are activated per token, the entire model must reside in memory. Existing expert pruning methods primarily rely on independent ranking, failing to account for the complex inter-dependencies and redundancies between experts. In this paper, we formulate post-training MoE pruning as a reconstruction-driven subset selection problem, aiming to minimize layer-output distortion under a cardinality constraint. We introduce SCHUR-A*, an algorithm that leverages A* search to achieve globally optimal expert selection within each layer. To maintain computational tractability, we derive a novel, admissible heuristic upper bound using a Schur-complement-based relaxation of the reconstruction objective. This tight bound allows for aggressive pruning of the search space while mathematically guaranteeing optimalit

y. Furthermore, we propose an automated strategy to balance fidelity and memory reduction across heterogeneous layers via knee-point detection. Extensive experiments on Qwen3-30B-A3B demonstrate that SCHUR-A* significantly outperforms greedy and ranking-based baselines, maintaining comparable performance even under aggressive pruning ratios.

Move-Then-Operate: Behavioral Phasing for Human-Like Robotic Manipulation
Haoming Xu, Lei Lei, Jie Gu, Chu Tang, Jingmin Chen, Rui-Qi Wang
We present Move-Then-Operate, a Vision–language–action framework that explicitly decouples robotic manipulation into two distinct behavioral phases: coarse relocation (move) and contact-critical interaction (operate). Unlike monolithic policies that conflate these heterogeneous regimes, our architecture employs a dual-expert policy routed by a learnable phase selector, introducing a structural inductive bias that isolates phase-specific dynamics. Phase labels are automatically generated via an MLLM-based pipeline conditioned on lightweight contextual cues such as end-effector velocity and subtask decomposition to ensure alignment with human motor patterns. Evaluated on the RoboTwin2 benchmark, our method achieves an average success rate of 68.9%, outperforming the monolithic π_0 baseline by +24%. It matches or exceeds models trained on $10\times$ more data and reaches peak performance in 40% fewer training steps, demonstrating that architectural disentanglement of move and operate phases is a highly effective and efficient strategy for mastering high-precision manipulation.

CIRBench: Evaluating Large Language Models as LLVM IR Optimizers
Zi Yang, Haifeng Ding, Fei Liu, Yingying Cheng, Han Cheng, Zhilei Chai, Haojie Zhou
Large language models are beginning to introduce a new paradigm for compilation: instead of only assisting at the source level, they can operate directly on **intermediate representations (IRs)**, the compiler’s internal code representation, Early studies suggest that LLM-guided optimization can sometimes rival traditional compiler optimizations on selected programs, but evidence remains fragmented.
Yet the community still lacks a rigorous IR-level benchmark that tests whether a model not only understands IR but can rewrite it under compiler-grade semantic constraints with meaningful performance impact.
We present **CIRBench**, a benchmark of 800 curated IR instances spanning four compiler-oriented tracks: Analysis infers IR properties, Repair fixes invalid IR, Refactor applies a single semantics-preserving compiler optimization, and Transform performs performance-oriented rewrites, together mirroring core optimization responsibilities in modern compilers.
CIRBench combines verifier, equivalence checking, and end-to-end performance measurement into a unified, layered correctness-aware evaluation of LLMs on IR.
On six mainstream LLMs, CIRBench shows that current models fail on many IR analysis and rewriting instances and on median underperform the compiler baseline, but we also observe a maximum speedup of $4.96\times$ over -O3.
These findings highlight both the opportunities and the remaining challenges of using LLMs inside optimizing compilers.
****

CoCoReviewBench: A Completeness- and Correctness-Oriented Benchmark for AI Reviewers
Hexuan Deng, Xiaopeng Ke, Yichen Li, Ruina Hu, Dehao Huang, Derek F. Wong, Yue Wang, Xuebo Liu, Min Zhang
Despite the rapid development of AI reviewers, evaluating such systems remains challenging: metrics favor overlap with human reviews over correctness. However, since human reviews often cover only a subset of salient issues and sometimes contain mistakes, they are unreliable as gold references. To address this, we build category-specific benchmark subsets and skip evaluation when the corresponding human reviews are missing to strengthen ***Co***mpleteness. We also leverage reviewer--author--meta-review discussions as expert annotations and filter unreliable reviews accordingly to strengthen ***Co***rrectness. Finally, we introduce `

CoCoReviewBench`, which curates 3,900 papers from ICLR and NeurIPS to enable rel
iable and fine-grained evaluation of AI reviewers. Analysis shows that AI review
ers remain limited in correctness and are prone to hallucinations, and highlight
s reasoning models as more effective reviewers, motivating further directions fo
r improving AI reviewers. Benchmarks and models are available at <https://github
.com/hexuandeng/CoCoReviewBench>.

X-EviProbe: Post-hoc Parameter-Free Evidential Uncertainty Quantification for Fr
ozen Graph Neural Networks
Chenghua Guo, Sihong Xie, Xi Zhang
Reliable uncertainty quantification (UQ) is crucial for deploying graph neural n
etworks (GNNs) in safety-critical settings, yet dominant solutions either rely o
n costly multi-pass sampling or require retraining—often using *black-box auxili
ary* models—to obtain evidential semantics. We propose **X-EviProbe**, a simple
and parameter-free *post-hoc* framework that turns a *frozen* GNN into an eviden
tial predictor with a decomposable view of epistemic vs. aleatoric uncertainty.
 X-EviProbe constructs class-wise Dirichlet evidence by probing the frozen laten
t space and the model’s native outputs, and incorporates graph structure via lig
htweight evidence-strength propagation. This yields a transparent evidential rep
resentation without retraining or additional neural components. Extensive exper
iments on seven benchmarks show that X-EviProbe consistently ranks among the top
 methods for both OOD detection and misclassification detection, improving AUROC
 by up to **33.4%** and **8.7%** over the strongest baselines.

Lifting Traces to Logic: Programmatic Skill Induction with Neuro-Symbolic Learni
ng for Long-Horizon Agentic Tasks
Jie-Jing Shao, Haiyan Yin, Yueming Lyu, Xingrui Yu, Lan-Zhe Guo, Ivor Tsang, Jam
es Kwok, Yu-Feng Li
Foundation model-driven agents often struggle with long-horizon planning due to
the transient nature of purely prompting-based reasoning. While existing skill i
nduction methods mitigate this by distilling experience into state-blind paramet
erized scripts, they fail to capture the conditional logic required for robust e
xecution in dynamic environments. In this paper, we propose Neuro-Symbolic Skill
 Induction (NSI), a framework that lifts interaction traces into modular, logic-
grounded programs. By synthesizing explicit control flows and dynamic variable b
inding, NSI empowers agents to discover when and why to act. This paradigm enabl
es the efficient generalization, allowing agents to induce skills from few-shot
examples and flexibly adapt to unseen goals. Experiments on a series of agentic
tasks demonstrate that NSI consistently outperforms state-of-the-art baselines,
empowering agents to self-evolve into architects of logic-grounded skills. Proje
ct Page: https://sh-jj.github.io/NSI.

Agent Primitives: Reuseable Latent Building Blocks for Multi-Agent Systems
Haibo Jin, Peng Kuang, Ye Yu, Xiaopeng Yuan, Haohan Wang
While existing multi-agent systems (MAS) can handle complex problems by enabling
 collaboration among multiple agents, they are often highly task-specific, relyi
ng on manually crafted agent roles and interaction prompts, which leads to incre
ased architectural complexity and limited reusability across tasks. Moreover, mo
st MAS communicate primarily through natural language, making them vulnerable to
 error accumulation and instability in long-context, multi-stage interactions wi
thin internal agent histories.

In this work, we propose \textbf{Agent Primitives}, a set of reusable latent bui
lding blocks for LLM-based MAS. Inspired by neural network design, where complex
 models are built from reusable components, we observe that many existing MAS ar
chitectures can be decomposed into a small number of recurring internal computat
ion patterns. Based on this observation, we instantiate three primitives (Review
, Voting and Selection, and Planning and Execution), all communicating via key–v
alue (KV) cache to mitigate information degradation across multi-stage interacti
ons. To enable automatic system construction, an Organizer agent automatically s

elects and composes primitives for each query, guided by a lightweight knowledge pool of previously successful configurations, forming a primitive-based MAS.

Experiments show that primitives-based MAS improve average accuracy by 12.0–16.5 \% over single-agent baselines, reduce token usage and inference latency by approximately 3$\times$–4$\times$ compared to text-based MAS, while incurring only 1.3$\times$–1.6$\times$ overhead relative to single-agent inference and providing more stable performance across model backbones.

Learning the ESG Geometry with Domain Aware Language Models
Kunal Pradeep Pimparkhede, Chirayu Chaurasia, Jatin Roy, Mahesh Mohan M R
Responsible investing aims to generate positive impact across Environment (E), Society (S), and Governance (G), and rating companies along these dimensions is now widespread, making ESG scores highly popular. Allocating retail capital with sustainability in mind could be transformational, yet it remains unclear how individual investors can do so in practice. Current ESG solutions cannot model high-dimensional, multi-modal time series capturing the joint evolution of ESG risks, financial returns, news, and sentiment, even though this domain requires jointly reasoning over distinct numerical signals where both numerical proximity and semantic type must be preserved. To bridge this gap, we introduce a novel domain-aware $\textbf{representation learning framework}$ that learns geometry-preserving representations for heterogeneous time series using value-aware tokens with block-wise $\textbf{orthogonal embeddings}$. To capture trajectory-level structure, we introduce $\textbf{FACET}$ tokens and train the model using a geometry-preserving loss. The resulting model jointly learns to forecast future values and to organize entities in a representation space that reflects their temporal evolution. Trained on ESG, returns, news, and sentiment, the domain-aware LLM learns a representation space that enables accurate ESG forecasting, trajectory-based grouping, and latent-space search for superior asset selection and downstream application like portfolio rebalancing
****
Sparse ActionGen: Accelerating Diffusion Policy with Real-time Pruning
Kangye Ji, Jianbo Zhou, Yuan Meng, Ye Li, Hanyun Cui, Zhi Wang
Diffusion Policy has dominated action generation due to its strong capabilities for modeling multi-modal action distributions, but its multi-step denoising processes make it impractical for real-time visuomotor control.
Existing caching-based acceleration methods typically rely on $\textit{static}$ schedules that fail to adapt to the \textit{dynamics} of robot-environment interactions, thereby leading to suboptimal performance.
In this paper, we propose $\underline{\textbf{S}}$parse $\underline{\textbf{A}}$ction$\underline{\textbf{G}}$en $(\textbf{SAG})$ for extremely sparse action generation. To accommodate the iterative interactions, SAG customizes a rollout-adaptive prune-then-reuse mechanism that first identifies prunable computations globally and then reuses cached activations to substitute them during action diffusion. To capture the rollout dynamics, SAG parameterizes an observation-conditioned diffusion pruner for environment-aware adaptation and instantiates it with a highly parameter- and inference-efficient design for real-time prediction. Furthermore, SAG introduces a one-for-all reusing strategy that reuses activations across both timesteps and blocks in a zig-zag manner, minimizing the global redundancy. Extensive experiments on multiple robotic benchmarks demonstrate that SAG achieves up to 4$\times$ generation speedup without sacrificing performance. Project Page: https://sparse-actiongen.github.io/.

Optimal and Scalable MAPF via Multi-Marginal Optimal Transport and Schrödinger Bridges
Usman Khan, Joseph W Durham
We consider anonymous multi-agent path finding (MAPF) where a set of robots is tasked to travel to a set of targets on a finite, connected graph. We show that MAPF can be cast as a special class of multi-marginal optimal transport (MMOT) problems with an underlying Markovian structure, under which the exponentially lar

ge MMOT collapses to a linear program (LP) polynomial in size. Focusing on the a nonymous setting, we establish conditions under which the corresponding LP is fe asible, totally unimodular, and yields min-cost, integral~$(\{0,1\})$ transports that do not overlap in both space and time. To adapt the approach to large-scal e problems, we cast the MAPF-MMOT in a probabilistic framework via Schrödinger b ridges. Under standard assumptions, we show that the Schrödinger bridge formulat ion reduces to an entropic regularization of the corresponding MMOT that admits an iterative Sinkhorn-type solution. The Schrödinger bridge, being a probabilist ic framework, provides a shadow (fractional) transport that we use as a template to solve a reduced LP and demonstrate that it results in near-optimal, integral transports at a significant reduction in complexity. Extensive experiments high light the optimality and scalability of the proposed approaches.

3DPoV: Improving 3D understanding via Patch Ordering on Videos
Ioana Simion, Mohammadreza Salehi, Shashanka Venkataramanan, Cees G. M. Snoek, Y uki M Asano
Visual foundation models have achieved remarkable progress in scale and versatil ity, yet understanding the 3D world remains a fundamental challenge. While 2D im ages contain cues about 3D structure that humans readily interpret, deep models often fail to exploit them, underperforming on tasks such as multiview semantic consistency--crucial for applications including robotics and autonomous driving. We propose a self-supervised approach to enhance the 3D understanding of vision foundation models by (i) introducing a temporal nearest-neighbor consistency lo ss that finds corresponding points across video frames and enforces consistency between their nearest neighbors, (ii) incorporating reference-guided ordering th at requires patch-level features to be not only expressive but also consistently aligned, and (iii) constructing a mixture of video datasets tailored to these o bjectives, thereby leveraging rich 3D information. Our method, 3DPoV, achieves s tate-of-the-art performance in keypoint matching under viewpoint variation, as w ell as in depth and surface normal estimation, and consistently improves a diver se set of backbones, including DINOv3.

Sparse and Faithful Local Explanations with Piecewise Linear Surrogates
Yixin Wang, Yucheng Dong
Local post-hoc explanations are widely used to understand black-box models on ta bular data, with Local Interpretable Model-agnostic Explanations (LIME) being a popular approach. LIME approximates a black-box model using a sparse linear surr ogate in a local neighborhood, implicitly assuming feature-wise linear homogenei ty. However, this assumption often fails when local feature effects exhibit hete rogeneous or nonlinear behaviors, resulting in unfaithful and unstable explanati ons. Moreover, LIME relies on a decoupled feature selection procedure that is no t aligned with the surrogate modeling objective, further exacerbating instabilit y under local sampling. To address these limitations, we propose PL-LIME, a two- stage sparse local explanation framework that ensures objective consistency acro ss stages. PL-LIME models feature-wise local effects using instance-anchored pie cewise linear functions, providing a minimal yet principled extension beyond lin ear surrogates under a fixed explanation budget. Sparsity is enforced through a decoupled nonnegative shrinkage procedure that directly scales the estimated loc al effects, improving stability while preserving interpretability. Experiments o n synthetic and real-world datasets demonstrate that PL-LIME achieves higher loc al fidelity and stability, and provides more reliable local explanations that ca pture finer-grained local effect structures than LIME.
****

Representation Unlearning: Forgetting through Information Compression
Antonio Almudévar, Alfonso Ortega
Machine unlearning seeks to remove the influence of specific training data from a model, a need driven by privacy regulations and robustness concerns. Existing approaches typically modify model parameters, but such updates can be unstable, computationally costly, and limited by local approximations. We introduce Repres entation Unlearning, a framework that performs unlearning directly in the model’

s representation space. Instead of modifying model parameters, we learn a transf
ormation over representations that imposes an information bottleneck: maximizing
 mutual information with retained data while suppressing information about data
to be forgotten. We derive variational surrogates that make this objective tract
able and show how they can be instantiated in two practical regimes: when both r
etain and forget data are available, and in a zero-shot setting where only forge
t data can be accessed. Experiments across several benchmarks demonstrate that R
epresentation Unlearning achieves more reliable forgetting, better utility reten
tion, and greater computational efficiency than parameter-centric baselines.

Factored Causal Representation Learning for Robust Reward Modeling in RLHF
Yupei Yang, Lin Yang, Wanxi Deng, Lin Qu, Fan Feng, Biwei Huang, Shikui Tu, Lei
Xu
A reliable reward model is essential for aligning large language models (LLMs) w
ith human preferences through reinforcement learning from human feedback (RLHF).
 However, standard reward models are susceptible to spurious features that are n
ot causally related to human labels. This can lead to *reward hacking*, where hi
gh predicted reward does not translate into better behavior. In this work, we ad
dress this problem from a causal perspective by proposing a factored representat
ion learning framework that decomposes the model’s contextual embedding into (1)
 causal factors that are sufficient for reward prediction and (2) non-causal fac
tors that capture reward-irrelevant attributes such as length or sycophantic bia
s. The reward head is then constrained to depend only on the causal component. I
n addition, we introduce an adversarial head trained to predict reward from the
non-causal factors, while applying gradient reversal to discourage them from enc
oding reward-relevant information. Experiments on both mathematical and dialogue
 tasks demonstrate that our method learns more robust reward models and consiste
ntly improves downstream RLHF performance over state-of-the-art baselines. Analy
ses on length and sycophantic bias further validate the effectiveness of our met
hod in mitigating reward hacking behaviors.
****

CombinationTS: A Modular Framework for Understanding Time-Series Forecasting Mod
els
Xiaorui Wang, Fanda Fan, Chenxi Wang, Yuxuan Yang, Rui Tang, Kuoyu Gao, simiao p
ang, Yuanfeng Shang, Zhipeng Liu, Wanling Gao, Lei Wang, Jianfeng Zhan
Recent progress in time-series forecasting has led to rapidly increasing archite
ctural complexity, yet many reported State-of-the-Art gains are statistically fr
agile or misattributed.
We argue that progress requires a shift from model selection to modular attribut
ion, identifying which components truly drive performance.
We propose CombinationTS, a self-contained probabilistic evaluation framework gr
ounded in Evaluatology, the science of uncovering the effects.
It decomposes forecasting models into orthogonal modules—Input Transformation, E
mbedding, Encoder, Decoder, and Output Transformation—and evaluates them under a
 shared evaluation condition space.
By quantifying each component via marginalized performance (μ) and stability
 (σ), CombinationTS enables robust attribution beyond fragile point estim
ates.
Through large-scale paired evaluation, we uncover the Identity Paradox: once the
 data view (Embedding) is well-designed, a parameter-free Identity Encoder often
 matches or outperforms complex backbones.
****

Trajectory Consistency for One-Step Generation on Euler Mean Flows
Zhiqi Li, Yuchen Sun, Duowen Chen, Jinjin He, Bo Zhu
We propose \emph{Euler Mean Flows (EMF)}, a flow-based generative framework for
one-step and few-step generation that enforces long-range trajectory consistency
 with minimal sampling cost.
The key idea of EMF is to replace the trajectory consistency constraint, which i
s difficult to supervise and optimize over long time scales, with a principled l
inear surrogate that enables direct data supervision for long-horizon flow-map c

ompositions. We derive this approximation from the semigroup formulation of flo
w-based models and show that, under mild regularity assumptions, it faithfully a
pproximates the original consistency objective while being substantially easier
to optimize. This formulation leads to a unified, JVP-free training framework t
hat supports both u-prediction and x_1-prediction variants, avoiding explici
t Jacobian computations and significantly reducing memory and computational over
head. Experiments on image synthesis, particle-based geometry generation, and f
unctional generation demonstrate improved optimization stability and sample qual
ity under fixed sampling budgets, together with approximately 50% reductions
in training time and memory consumption compared to existing one-step methods fo
r image generation.
****

Stochastic Order Learning: An Approach to Rank Estimation Using Noisy Data
Chaewon Lee, Seon-Ho Lee, Chang-Su Kim
Rank estimation under label noise poses a fundamental challenge, as ordinal anno
tations often exhibit structured uncertainty rather than simple label corruption
. In this paper, we reformulate rank estimation with noisy ordinal labels as a s
tochastic ordering problem, in which each instance is inherently associated with
 multiple plausible ranks instead of a single deterministic label. Based on this
 view, we propose stochastic order learning (SOL), a learning framework that cap
tures ordinal label uncertainty and learns an embedding space through two comple
mentary objectives: a discriminative loss that structures instance-centroid inte
ractions and a stochastic order loss that enforces probabilistic ordering relati
ons between instances. Extensive experiments across diverse datasets demonstrate
 that SOL enables reliable rank estimation under various types and levels of lab
el noise. The source code is available at https://github.com/cwlee00/SOL.

Differentially Private Preference Data Synthesis for Large Language Model Alignm
ent
Fengyu Gao, Jing Yang
Preference alignment is a crucial post-training step for large language models (
LLMs) to ensure their outputs align with human values. However, post-training on
 real human preference data raises privacy concerns, as these datasets often con
tain sensitive user prompts and human judgments. To address this, we propose **D
PPrefSyn**, a novel algorithm for generating differentially private (DP) synthet
ic preference data to enable privacy-preserving preference alignment. DPPrefSyn
is a principled framework grounded in the Bradley–Terry preference model and the
 intrinsic geometric structure of pairwise human preference data. It first learn
s an underlying preference model from private data with formal differential priv
acy guarantees, and then leverages the learned model together with public prompt
s to synthesize high-quality preference data. It exploits the shared linear stru
cture of per-cluster reward models to effectively capture heterogeneous human pr
eferences in private datasets, and leverages DP Principal Component Analysis (DP
-PCA) to improve learning accuracy. Extensive experimental results demonstrate t
hat DPPrefSyn achieves competitive alignment performance under strong DP guarant
ees. These findings highlight the potential of synthetic preference data as a pr
actical alternative for privacy-preserving preference alignment across a broad r
ange of applications. To the best of our knowledge, this is the first work to ge
nerate DP synthetic preference data for LLM alignment.
****

Private and Stable Test-time Adaptation with Differential Privacy
Zefeng Li, Qiaoyue Tang, Mathias Lécuyer, Evan Shelhamer
Test-time adaptation (TTA) can reduce error on new and different data by updatin
g the model on these inputs during inference.
However, these updates raise the issue of privacy w.r.t. the testing data, becau
se the model parameters now depend on all past inputs.
To control this privacy risk, we cast multiple popular TTA methods (Tent, EATA,
SAR, DeYO, and COME) into differential privacy (DP) forms that apply per-sample
gradient clipping and Gaussian noise for all updates.
On ImageNet-C, our DP-TTA methods provide adequate privacy at small cost to accu

racy, and in the low-privacy regime the clipping mechanism of DP can even improv
e the accuracy and stability of adaptation in the continual setting.
These improvements to privacy and accuracy come at only modest computational ove
rhead.
These first results on private TTA raise awareness of the issue,
inform the development of more private test-time updates, and identify per-sampl
e clipping as an effective technique for improving the accuracy and stability of
 adaptation.

Degradation-Aware Metric Prompting for Hyperspectral Image Restoration
Binfeng Wang, Di Wang, Haonan Guo, Ying Fu, Jing Zhang
Unified hyperspectral image (HSI) restoration aims to recover diverse degradatio
ns within a single model. However, current methods often rely on impractical exp
licit priors or opaque black-box representations that overfit to training distri
butions, hampering generalization to unseen scenarios. To bridge this gap, we pr
opose Degradation-Aware Metric Prompting (DAMP), a novel framework that characte
rizes multi-dimensional degradations through interpretable spatial-spectral metr
ics. These metrics serve as Degradation Prompts (DP), enabling the model to capt
ure shared characteristics across tasks and adapt to unknown corruptions. Centra
l to our framework is the Degradation-Adaptive Mixture-of-Experts (DAMoE), where
 Spatial-Spectral Adaptive Modules (SSAMs) serve as experts that utilize learnab
le fusion coefficients to specialize in distinct degradation degrees. By using D
P as a gating router, DAMoE dynamically activates specialized experts tailored t
o the specific degradation profile. Extensive experiments on natural and remote
sensing HSI datasets demonstrate that DAMP achieves state-of-the-art performance
 and exhibits exceptional zero-shot generalization on unseen restoration tasks.
Code is publicly available at \href{DAMP}{https://github.com/MiliLab/DAMP}.
****

CARE: Class-Adaptive Expert Consensus for Reliable Learning with Long-Tailed Noi
sy Labels
Mengke Li, Haiquan Ling, Lihao Chen, Yang Lu, Yiqun Zhang, Hui Huang
Learning from real-world data is frequently hindered by the compound challenge o
f long-tailed class distributions and noisy annotations.
Existing methods partially address these issues but typically ignore the non-uni
form impact of label noise across classes, resulting in ineffective correction f
or tail classes and over-regularization for head classes.
To address this issue, we propose Class-Adaptive Rectification with Experts (CAR
E), a parameter-efficient framework that leverages three complementary supervisi
on sources from vision-language models (VLM): observed noisy labels, VLM text em
beddings, and visual features.
CARE introduces a class-adaptive expert consensus mechanism that enforces strict
er agreement for tail classes and more permissive agreement for head classes bas
ed on class frequency.
By aggregating high-confidence predictions across these sources, CARE filters un
reliable signals and recalibrates class distributions, yielding more reliable re
ctification under long-tailed distributions.
Extensive experiments on both synthetic and real-world benchmarks demonstrate th
at CARE consistently outperforms state-of-the-art methods, achieving up to 3.0\%
 performance gains.
The source code is available at https://github.com/qwq123-study/CARE.

Geometry of Reason: Spectral Signatures of Valid Mathematical Reasoning
Valentin NOËL
Verifying whether a language model is genuinely reasoning or pattern-matching re
mains an open problem: learned verifiers are expensive, and output-based heurist
ics are brittle.
We show that valid mathematical reasoning induces a measurable, training-free sp
ectral signature in transformer attention.
By treating each attention matrix as a weighted token graph, we extract four dia
gnostics: Fiedler value, High-Frequency Energy Ratio (HFER), spectral entropy, a

nd smoothness, that require no learned parameters.
Experiments across seven models from four architectural families yield effect si zes up to Cohen's $d = 3.30$ ($p < 10^{-116}$), enabling 85-96% single-thres hold classification accuracy.
Two findings sharpen the interpretation.
First, \emph{Platonic validity}: the spectral signal tracks logical coherence ra ther than compiler acceptance, proofs rejected for timeouts or missing imports a re correctly classified as valid, a distinction confirmed by a manual audit ($\k appa = 0.82$, $n = 51$).
Second, \emph{architectural determinism}: Sliding Window Attention shifts the di scriminative feature from HFER to smoothness ($d = 2.09$, $p < 10^{-48}$), showi ng that attention design governs which spectral channel encodes reasoning qualit y.
Causal ablation confirms the signature traces induction-head circuits.
The method generalises to informal chain-of-thought ($d = 0.78$, $p < 10^{-3}$), and in proof search, HFER reranking improves Best-of-16 Pass@1 by $+4.4$-6.6% , matching 98% of the AUC of fully supervised probes with zero labels.
Spectral graph analysis is a principled, architecture-aware primitive for reason ing verification.

Towards Solving the Gilbert-Pollak Conjecture via Large Language Models
Yisi Ke, Tianyu Huang, Yankai Shu, Di He, Jingchu Gai, Liwei Wang
The Gilbert-Pollak Conjecture, also known as the Steiner Ratio Conjecture, state s that for any finite point set in the Euclidean plane, the Steiner minimum tree has length at least $\sqrt{3}/2 \approx 0.866$ times that of the Euclidean mini mum spanning tree (the Steiner ratio). A sequence of improvements through the 19 80s culminated in a lower bound of 0.824, with no substantial progress reporte d over the past three decades. Recent advances in LLMs have demonstrated strong performance on contest-level mathematical problems, yet their potential for addr essing open, research-level questions remains largely unexplored. In this work, we present a novel AI system for obtaining tighter lower bounds on the Steiner r atio. Rather than directly prompting LLMs to solve the conjecture, we task them with generating rule-constrained geometric lemmas implemented as executable code . These lemmas are then used to construct a collection of specialized functions, which we call verification functions, that yield theoretically certified lower bounds of the Steiner ratio. Through progressive lemma refinement driven by refl ection, the system establishes a new certified lower bound of 0.8559 for the Ste iner ratio. The entire research effort involves only thousands of LLM calls, de monstrating the strong potential of LLM-based systems for advanced mathematical research.

Formally Exploring Visual Anomaly Detection Evaluation Metrics
Nasar Iqbal, Dennis Wagner, Philipp Liznerski, Nabeel Hussain Syed, Sophie Felle nz, Niki Martinel, Marius Kloft
Inaccurate Visual Anomaly Detection (VAD) can lead to critical failures in safet y-sensitive domains, including autonomous navigation and industrial surveillance . With the increasing abundance and rapid proliferation of VAD algorithms, their reliable evaluation has become increasingly important and challenging. Commonly used evaluation metrics often fail to capture practically relevant aspects of m odel behavior, yielding inconsistent or misleading assessments by overlooking er rors such as redundant detections and the spatial distribution of false positive s. In this paper, we formalize the requirements for VAD evaluation by introducin g a set of axiomatic, verifiable properties that an evaluation metric should sat isfy. Through a systematic analysis of state-of-the-art evaluation methods, we s how that none satisfies all proposed properties. To address this gap, we introdu ce SAAM-ALARM, a novel evaluation metric that satisfies these properties. Our re sults show that SAAM-ALARM provides a more nuanced and theoretically sound asses sment, establishing a stronger standard for performance benchmarking in VAD.
****

Ellipsoidal Time Series Forecasting

Qilin Wang
We argue that long-horizon forecasting requires learning local Jacobians with explicit spectral structure, not only matching conditional means. Our method, Fern (\textbf{F}orecasting with \textbf{E}llipsoidal \textbf{R}epresentatio\textbf{N}s), invokes Brenier's theorem to directly parameterize the Jacobian as a symmetric positive semi-definite (SPD) factorization, treating forecasting as the optimal transport of probability mass from a fixed Gaussian source to data-dependent ellipsoids. This formulation avoids post-hoc eigendecomposition of dense Jacobians, enables efficient Householder-based orthogonal factors, and exposes interpretable diagnostics such as local stretching, spectral radius, and volume change. To rigorously evaluate robustness, we introduce controlled synthetic stress tests with nonstationary shocks, together with Wasserstein-based shape metrics and Effective Prediction Time. Fern demonstrates exceptional stability, outperforming baselines like DLinear and Koopa by over two orders of magnitude (up to $790\times$) on nonstationary settings where standard benchmarks fail to expose model brittleness.
****

Adaptive Generation of Bias-Eliciting Questions for LLMs
Robin Staab, Jasper Dekoninck, Maximilian Baader, Martin Vechev
Large language models (LLMs) are now widely deployed in user-facing applications, reaching hundreds of millions of users worldwide. Despite their widespread adoption, growing reliance on their outputs raises significant concerns, particularly as users may be exposed to model-inherent biases that disadvantage or stereotype certain groups. However, existing bias benchmarks commonly rely on simple templated prompts or restrictive multiple-choice questions that fail to capture the complexity of real-world user interactions. In this work, we address this gap by introducing a counterfactual framework that automatically generates realistic, open-ended questions for LLM bias evaluation. Through iterative question mutation, our approach systematically explores areas where models are most likely to exhibit biased behavior. Beyond just detecting harmful biases, we also capture increasingly relevant response dimensions, such as asymmetric refusals and explicit bias acknowledgment. Building on this, we construct CAB, a diverse and human-verified benchmark for realistic and nuanced bias evaluations on current frontier LLMs. Our evaluation using CAB highlights the continued need for fairness research by showing that all examined models exhibit persistent biases across certain scenarios.
****

Statistically Undetectable Backdoors in Deep Neural Networks
Andrej Bogdanov, Alon Rosen, Neekon Vafa
We show how an adversarial model trainer can plant backdoors in a large class of deep, feedforward neural networks. These backdoors are statistically undetectable in the white-box setting, meaning that the backdoored and honestly trained models are close in total variation distance, even given the full descriptions of the models (e.g., all of the weights). The backdoor provides access to invariance-based adversarial examples for every input, mapping distant inputs to unusually close outputs. However, without the backdoor, it is provably impossible (under standard cryptographic assumptions) to generate any such adversarial examples in polynomial time. Our theoretical and preliminary empirical findings demonstrate a fundamental power asymmetry between model trainers and model users.
****

Beyond Softmax: A Natural Parameterization for Categorical Random Variables
Alessandro Manenti, Cesare Alippi
Latent categorical variables are frequently found in deep learning architectures. They can model actions in discrete reinforcement-learning environments, represent categories in latent-variable models, or express relations in graph neural networks. Despite their widespread use, their discrete nature poses significant challenges to gradient-descent learning algorithms. While a substantial body of work has offered improved gradient estimation techniques, we take a complementary approach. Specifically, we: 1) revisit the ubiquitous *softmax* function and demonstrate its limitations from an information-geometric perspective; 2) replace

the *softmax* with the *catnat* function, a function composed by a sequence of h
ierarchical binary splits; we prove that this choice offers significant advantag
es to gradient descent due to the resulting diagonal Fisher Information Matrix.
A rich set of experiments - including graph structure learning, variational auto
encoders, and reinforcement learning - empirically show that the proposed functi
on improves the learning efficiency and yields models characterized by consisten
tly higher test performance. *Catnat* is simple to implement and seamlessly inte
grates into existing codebases. Moreover, it remains compatible with standard tr
aining stabilization techniques and, as such, offers a better alternative to the
 softmax function.
****

Escaping Mode Collapse in LLM Generation via Geometric Regulation
Xin Du, Kumiko Tanaka-Ishii
Mode collapse is a persistent challenge in generative modeling and manifests in
autoregressive text generation as behaviors ranging from explicit looping to
gradual loss of diversity and premature trajectory convergence. We take a
dynamical-systems view and reinterpret mode collapse as reduced state-space
accessibility caused by *geometric collapse*: during generation, the
model's internal trajectory becomes confined to a low-dimensional region of its
representation space. This implies mode collapse is not purely a token-level
phenomenon and cannot be reliably mitigated by symbolic constraints or
probability-only decoding heuristics. Guided by this perspective, we propose
Reinforced Mode Regulation (RMR), a lightweight, online state-space
intervention that regulates dominant self-reinforcing directions in the
Transformer value cache (implemented as low-rank damping). Across multiple large
language models, RMR substantially reduces mode collapse and enables stable,
high-quality generation at extremely low entropy rates (down to 0.8 nats/step),
whereas standard decoding typically collapses near 2.0 nats/step.
****

Learning to Search and Searching to Learn for Generalization in Planning
Michael Aichmüller, Yannik Hesse, Hector Geffner
Combinatorial generalization remains a central challenge in Deep Reinforcement L
earning (DRL). Classical planning provides a simple yet challenging setting to s
tudy this problem through explicit relational descriptions, without requiring le
arning from perception.
In sparse-reward domains, standard RL exploration via real-time search is ineffe
ctive, and learning-based planning methods often rely on expert demonstrations,
hindsight relabeling, or random walks from the goal state. In contrast, planners
 rely on best-first search methods such as $\mathrm{A}^\star$ to solve problems
from scratch. We propose a self-improving $\mathrm{WA}^\star$ learning framework
 in combination with a value heuristic represented by a Relational Graph Neural
Network: the heuristic guides search, and the resulting search data updates the
heuristic via Q-learning. This loop yields heuristics that can function as gen
eral policies and solve new instances even without search, where DRL otherwise f
ails, as we show on puzzles such as Sokoban, PushWorld, The Witness, and the 202
3 International Planning Competition benchmarks. Notably, we demonstrate strong
zero-shot generalization: For example, heuristics trained on Blocksworld instanc
es with fewer than 30 blocks successfully solve instances with 488 blocks wi
thout search.
****

Optimized Deferral for Imbalanced Settings
Corinna Cortes, Anqi Mao, Mehryar Mohri, Yutao Zhong
Learning algorithms can be significantly improved by routing complex or uncertai
n inputs to specialized experts, balancing accuracy with computational cost. Thi
s approach, known as *learning to defer*, is essential in domains like natural l
anguage generation, medical diagnosis, and computer vision, where an effective d
eferral can reduce errors at low extra resource consumption. However, the two-st
age learning to defer setting, which leverages existing predictors such as a col
lection of LLMs or other classifiers, often faces challenges due to an expert im
balance problem. This imbalance can lead to suboptimal performance, with deferra

l algorithms favoring the majority expert. We present a comprehensive study of t
wo-stage learning to defer in expert imbalance settings. We cast the deferral lo
ss optimization as a novel cost-sensitive learning problem over the input-expert
 domain. We derive new margin-based loss functions and guarantees tailored to th
is setting, and develop novel algorithms for cost-sensitive learning. Leveraging
 these results, we design principled deferral algorithms, MILD (*Margin-based Im
balanced Learning to Defer*), specifically suited for expert imbalance settings.
 Extensive experiments demonstrate the effectiveness of our approach, showing cl
ear improvements over existing baselines on both image classification and real-w
orld Large Language Model (LLM) routing tasks.

Negatives-Dominant Contrastive Learning for Generalization in Imbalanced Domains
Meng Cao, Jiexi Liu, Songcan Chen
Imbalanced Domain Generalization (IDG) focuses on mitigating both *domain and la
bel shifts*, both of which fundamentally shape the model's decision boundaries,
particularly under heterogeneous long-tailed distributions across domains.
Despite its practical significance, it remains underexplored, primarily due to t
he *technical* complexity of handling their entanglement and the paucity of *the
oretical* foundations.
In this paper, we begin by *theoretically* establishing the generalization bound
 for IDG, highlighting the role of posterior discrepancy and decision margin.
This bound motivates us to focus on directly steering decision boundaries, marki
ng a clear departure from existing methods.
Then, we *technically* propose a novel Negative-Dominant Contrastive Learning (N
DCL) for IDG to enhance discriminability while enforce posterior consistency acr
oss domains.
Specifically, inter-class decision-boundary separation is enhanced by placing gr
eater emphasis on negatives as the primary signal in our contrastive learning, n
aturally amplifying gradient signals for minority classes to avoid the decision
boundary being biased toward majority classes.
Intra-class compactness is encouraged through a re-weighted cross-entropy strate
gy, and posterior consistency across domains is enforced through a prediction-ce
ntral alignment strategy.
Finally, rigorous yet challenging experiments on benchmarks validate the effecti
veness of our NDCL.
The code is available at https://github.com/Alrash/NDCL.

Fairness in Aggregation: Optimal Top-k and Improved Full Ranking
Diptarka Chakraborty, Arya Mazumdar, Barna Saha, Alvin Hong Yao Yan
Ensuring fairness in algorithmic ranking systems is a critical challenge with si
gnificant societal implications for hiring, recommendations, web search, and dat
a management. Standard methods for aggregating multiple preference orders into a
 consensus ranking may perpetuate and even amplify the lack of representation of
 underrepresented groups. To address this, recent research has focused on incorp
orating fairness constraints to ensure the presence of different groups in the t
op-k positions of the final aggregate ranking.

We study two fairness-aware variants under the well-known Spearman footrule, whi
ch corresponds to the L_1 distance between rankings. First, we address the pra
ctically salient task of computing a fair aggregate top-k ranking -- crucial i
n settings like recommendations and hiring where selection is primarily based on
 the top-k results -- and present the first optimal algorithm for this problem
. Second, we consider fair (full) rank aggregation over all candidates (not spec
ifically on top-k). We already know of a 3-approximation for this fair rank
aggregation variant (Wei et al., SIGMOD’22; Chakraborty et al., NeurIPS’22), whe
reas an exact algorithm exists for the corresponding unconstrained (unfair) vers
ion (Dwork et al., WWW’01). Closing the computational gap between fair and uncon
strained rank aggregation has remained a tantalizing open problem. We make signi
ficant progress by giving a 2-approximation algorithm for fair (full) rank agg

regation, improving substantially over the previous 3-approximation. Further, we complement our theoretical contributions with experiments on different real-world datasets, which corroborate our theoretical results and demonstrate strong empirical performance relative to state-of-the-art baselines.
****
Data- and Variance-dependent Regret Bounds for Online Tabular MDPs
Mingyi Li, Taira Tsuchiya, Kenji Yamanishi
This work studies online episodic tabular Markov decision processes (MDPs) with known transitions and develops best-of-both-worlds algorithms that achieve refined data-dependent regret bounds in the adversarial regime and variance-dependent regret bounds in the stochastic regime. We quantify MDP complexity using a first-order quantity and several new data-dependent measures for the adversarial regime, including a second-order quantity and a path-length measure, as well as variance-based measures for the stochastic regime. To adapt to these measures, we develop algorithms based on global optimization and policy optimization, both built on optimistic follow-the-regularized-leader with log-barrier regularization. For global optimization, our algorithms achieve first-order, second-order, and path-length regret bounds in the adversarial regime, and in the stochastic regime, they achieve a variance-aware gap-independent bound and a variance-aware gap-dependent bound that is polylogarithmic in the number of episodes. For policy optimization, our algorithms achieve the same data- and variance-dependent adaptivity, up to a factor of the episode horizon, by exploiting a new optimistic Q-function estimator. Finally, we establish regret lower bounds in terms of data-dependent complexity measures for the adversarial regime and a variance measure for the stochastic regime, implying that the regret upper bounds achieved by the global-optimization approach are nearly optimal.

MacroGuide: Topological Guidance for Macrocycle Generation
Alicja Maksymiuk, Alexandre Duplessis, Michael M. Bronstein, Alexander Tong, Fernanda Duarte, Ismail Ilkan Ceylan
Macrocycles are ring-shaped molecules that offer a promising alternative to small-molecule drugs due to their enhanced selectivity and binding affinity against difficult targets. Despite their chemical value, they remain underexplored in generative modeling, likely owing to their scarcity in public datasets and the challenges of enforcing topological constraints in standard deep generative models. We introduce MacroGuide: Topological Guidance for Macrocycle Generation, a diffusion guidance mechanism that uses Persistent Homology to steer the sampling of pretrained molecular generative models toward the generation of macrocycles, in both unconditional and conditional (protein pocket) settings. At each denoising step, MacroGuide constructs a Vietoris-Rips complex from atomic positions and promotes ring formation by optimizing persistent homology features. Empirically, applying MacroGuide to pretrained diffusion models increases macrocycle generation rates from 1% to 99%, while matching or exceeding state-of-the-art performance on key quality metrics such as chemical validity, diversity, and PoseBusters checks. The implementation can be found at https://github.com/ala1705/MacroGuide.
****
FS-I2P: A Hierarchical Focus–Sweep Registration Network with Dynamically Allocated Depth
Zhixin Cheng, Yujia Chen, Xujing Tao, Bohao Liao, Xiaotian Yin, Baoqun Yin, Tianzhu Zhang
Image-to-point cloud registration is often challenged by viewpoint changes, cross-modal discrepancies, and repetitive textures, which induce scale ambiguity and consequently lead to erroneous correspondences. Recent detection-free methods alleviate this issue by leveraging multi-scale features and transformer-based interactions. However, they still suffer from attention drift across layers and intra-scale inconsistencies, hindering precise registration.
Inspired by complex scene observation, we propose a ``Focus--Sweep'' paradigm and develop a Hierarchical Mamba Interaction Module within an SSM-based framework to enhance multi-level cross-modal feature association. In addition, we introduce a Dynamic Layer Allocation Strategy that adaptively determines the iteration d

epth to better exploit geometric constraints and improve matching robustness. Extensive experiments and ablations on two benchmarks, RGB-D Scenes V2 and 7-Scenes, demonstrate that our approach achieves state-of-the-art performance.
****
Quartet II: Accurate LLM Pre-Training in NVFP4 by Improved Unbiased Gradient Estimation
Andrei Panferov, Erik Schultheis, Soroush Tabesh, Dan Alistarh
The NVFP4 lower-precision format, supported in hardware by NVIDIA Blackwell GPUs, promises to allow, for the first time, end-to-end fully-quantized pre-training of massive models such as LLMs.

Yet, existing quantized training methods still sacrifice some of the representation capacity of this format in favor of more accurate unbiased quantized gradient estimation by stochastic rounding (SR), losing noticeable accuracy relative to standard FP16 and FP8 training.

In this paper, improve the state of the art for quantized training in NVFP4 via a novel unbiased quantization routine for micro-scaled formats, called MS-EDEN, that has more than 2x lower quantization error than SR. We integrate it into a novel fully-NVFP4 quantization scheme for linear layers, called Quartet II. We show analytically that Quartet II achieves consistently better gradient estimation across all major matrix multiplications, both on the forward and on the backward passes.

In addition, our proposal synergizes well with recent training improvements aimed specifically at NVFP4. We further validate Quartet II on end-to-end LLM training with up to 1.9B parameters on 38B tokens. We provide kernels for execution on NVIDIA Blackwell GPUs with up to 4.2x speedup over BF16.

Hallucination Detection from Structural Reasoning Model
Jianbo Sun, Pengkun Yang
Hallucinations pose a key challenge for large
language models, and chain-of-thought prompt■ing exposes intermediate reasoning but usually
treats traces as linear sequences, making cross■step dependencies and unsupported intermediate
claims difficult to identify. We propose a struc■tural reasoning model to describe interactions
among local reasoning steps. To detect halluci■nations, we extract a directed acyclic reasoning
graph over conditions and intermediate claims,
verify each claim against its parent nodes, and ag■gregate the step signals with a simple mass-flow
rule. Under a probabilistic erasure-gate abstrac■tion, we interpret this aggregation as measuring
information loss along the reasoning graph. Ex■periments on GSM8K, MATH, HumanEval, and
HotpotQA show that the proposed method is most
advantageous on longer, dependency-rich reason■ing traces such as math and code generation,
while remaining competitive on shorter factual
QA; these results provide a structured perspec■tive on chain-of-thought evaluation. All code and
data are available at https://github.com/soncheinbok/FlowScore.
****
Spatiotemporal Imputation with Graph-Informed Flow Matching
Zepeng Zhang, Aref Einizade, Jhony H. Giraldo, Olga Fink
Missing data is a common challenge in spatiotemporal systems, arising in applications such as air quality monitoring and urban traffic management.
Traditional machine learning approaches, like recurrent and graph neural networks, rely on iterative propagation, which tends to accumulate errors over time and space.
Recent diffusion-based methods mitigate error propagation but require iterative

sampling and often depend on problem-agnostic Gaussian priors, limiting both efficiency and effectiveness.
To address these limitations, we propose **GiFlow**, a *Graph-Informed Flow Matching* framework for spatiotemporal imputation.
GiFlow replaces the typical Gaussian prior with a graph-informed prior constructed via spatiotemporal filtering of observable signals, which better aligns the source distribution to the target and thereby simplifies the generation trajectory.
The flow field is parameterized by a hybrid vector field model that integrates spatial attention, temporal attention, and spatiotemporal propagation, enabling joint modeling of spatial and temporal dependencies.
Extensive experiments on both synthetic and real-world datasets demonstrate that the proposed GiFlow outperforms the state-of-the-art approaches in spatiotemporal imputation. The code is available at https://github.com/zepengzhang/GiFlow.
****

At the Edge of Understanding: Sparse Autoencoders Trace The Limits of Transformer Generalization
Praneet Suresh, Jack Stanley, Sonia Joseph, Luca Scimeca, Danilo Bzdok
Pre-trained transformers have demonstrated remarkable generalization abilities, at times extending beyond the scope of their training data. Yet, real-world deployments often face unexpected or adversarial data that diverges from training data distributions. Without explicit mechanisms for handling such shifts, model reliability and safety degrade, urging more disciplined study of out-of-distribution (OOD) settings for transformers. By systematic experiments, we present a mechanistic framework for delineating the precise contours of transformer model robustness. We find that OOD inputs, including subtle typos and jailbreak prompts, drive language models to operate on an increased number of fallacious concepts in their internals. We leverage this device to quantify and understand the degree of distributional shift in prompts, enabling a mechanistically grounded fine-tuning strategy to robustify LLMs. Expanding the very notion of OOD from input data to a model’s private computational processes—a new transformer diagnostic at inference time—is a critical step toward making AI systems safe for deployment across science, business, and government.

S2GS: Streaming Semantic Gaussian Splatting for Online Scene Understanding and Reconstruction
Renhe Zhang, Yuyang Tan, Jingyu Gong, Zhizhong Zhang, Lizhuang Ma, Yuan Xie, Xin Tan
Existing offline feed-forward methods for joint scene understanding and reconstruction on long image streams often perform global computation over an ever-growing set of past observations, causing runtime and GPU memory to increase rapidly with sequence length. We propose Streaming Semantic Gaussian Splatting (S2GS), a strictly causal and incremental framework that builds a 3D Gaussian semantic field from image streams without accessing future frames or reprocessing historical observations. S2GS continuously updates scene geometry, appearance, and instance-level semantics through a geometry--semantic decoupled dual-backbone design. The geometry branch performs causal modeling for incremental Gaussian updates, while the semantic branch leverages a 2D foundation vision model and a query-driven decoder to predict masks and identity embeddings. Query-level contrastive alignment and lightweight online association with an instance memory further stabilize temporal identities. Experiments show that S2GS matches or outperforms strong offline baselines, while substantially improving long-horizon scalability: it processes over 1,000 frames with much slower runtime and GPU memory growth, whereas offline global-processing baselines typically run out of memory at around 80 frames under the same setting. Project Page: https://stdcoutzrh.github.io/projects/s2gs/.

VeriSimpl: Robust Optimization Modeling from Natural Language using Simplification-based Verification
Sumaya Abdul Rahman, Seckhen Ariel Andrade Cuellar, Ghani Raissov, Mohammad Raza

Natural language interfaces can greatly benefit the accessibility and usability of optimization modeling, and recent advances in large language models (LLMs) show promise in automatically translating textual problem descriptions into executable solver formulations. However, a key challenge for existing approaches is to ensure that the inferred formulation correctly implements the intended task, even if it may execute without errors. We introduce VeriSimpl, a solver–LLM framework for robust natural-language-to-optimization formalization. Our approach is based on the idea of simplification-based verification, where the optimization solver is leveraged to generate simplified diagnostic queries about a candidate formulation to allow the LLM to tractably reason about the correctness of the formulation with respect to the task description. We present such simplification strategies along different dimensions with respect to problem constraints and decision variables, which allow the LLM to reason locally under fixed global contexts. Evaluations on a range of optimization benchmarks show how our approach provides consistent improvements in accuracy over existing methods, while also providing a novel high-precision self-verification signal.

ActiveUltraFeedback: Efficient Preference Data Generation using Active Learning
Davit Melikidze, Marian Schneider, Jessica Lam, Martin Wertich, Ido Hakimi, Barna Pásztor, Andreas Krause
Reinforcement Learning from Human Feedback (RLHF) has become the standard for aligning Large Language Models (LLMs), yet its efficacy is bottlenecked by the high cost of acquiring preference data, especially in low-resource and expert domains. To address this, we introduce ActiveUltraFeedback, a modular active learning pipeline that leverages uncertainty estimates to dynamically identify the most informative responses for annotation. Our pipeline facilitates the systematic evaluation of standard response selection methods alongside Double Reverse Thompson Sampling (DRTS) and DeltaUCB, two novel methods prioritizing response pairs with large predicted quality gaps, leveraging recent results showing that such pairs provide good signals for fine-tuning. Our experiments demonstrate that ActiveUltraFeedback yields high-quality datasets that lead to significant improvements in downstream performance, notably achieving comparable or superior results with as little as one-sixth of the annotated data relative to static baselines. Our pipeline is available at https://github.com/lasgroup/ActiveUltraFeedback and our preference datasets at https://huggingface.co/ActiveUltraFeedback.

InfVSR: Toward Consistency-Driven Streaming Generative Video Super-Resolution
Ziqing Zhang, Kai Liu, Zheng Chen, Xi Li, Yucong Chen, Bingnan Duan, Linghe Kong, Yulun Zhang
Real-world videos often extend over thousands of frames. Existing generative video super-resolution (VSR) approaches, however, face two persistent challenges when processing long sequences: (1) inefficiency due to the heavy cost of multi-step denoising for full-length sequences; and (2) poor consistency hindered by temporal decomposition that causes artifacts and discontinuities. To break these limits, we propose InfVSR, which reformulates VSR as an autoregressive-one-step-diffusion paradigm, and enables streaming inference with video diffusion priors. First, we adapt the pretrained DiT into a causal structure, maintaining both local and global coherence via rolling KV-cache and joint visual guidance. Second, we distill the diffusion process into a single step efficiently, with patch-wise pixel supervision and cross-chunk distribution matching. To fill the gap in long-form video evaluation, we build a new benchmark tailored for extended sequences and further introduce semantic-level metrics to comprehensively assess temporal consistency. Our method pushes the frontier of long-form VSR, achieves state-of-the-art quality with enhanced semantic consistency, and delivers up to 58x speed-up over existing methods such as MGLD-VSR. Our code and models are available at https://github.com/Kai-Liu001/InfVSR .

Beyond Point Predictions: Manifold Expansion and Dual Alignment for Robust Time Series Distillation
Junyao Hong, Zesheng Lai, Xinyi Xiao, Suyang Zhou, Aodong Shen, Youyong Kong

Knowledge Distillation (KD) promises to bridge the gap between the high computational costs of Transformer-based models and the expressiveness limitations of linear models in long-term time series forecasting. Many existing time series distillation methods inherit the computer vision paradigm, constraining student models by minimizing point-wise prediction matching (output-level distillation) errors. However, blindly mimicking teacher predictions, which can be uncertain, may induce negative transfer. To address this, we propose Dynamic Structural Distillation (DSD), a robust framework that goes beyond the prediction-matching paradigm. First, we design LMP-Net, leveraging manifold expansion to project features into a high-dimensional latent space, alleviating the expressiveness bottleneck while preserving lightweight inference. Second, to address token–point architectural mismatch, we propose Dual Manifold Alignment, employing Similarity-Preserving Knowledge Distillation (SPKD) and Optimal Transport (OT) to align features at the topological and geometric levels, respectively. Finally, we introduce Regime-Aware Adaptive Distillation (RAAD) to reduce the risk of teacher misguidance via a dataset-level regime prior and a confidence-based adaptive gating mechanism. Extensive experiments on five benchmarks show that DSD is compatible with diverse teacher architectures, improves lightweight students across data regimes, and achieves a favorable accuracy–efficiency trade-off. Code is available at https://github.com/jyh0526/DSD.

PLASH: Provably Linear-Time Attention with Selective Higher-Order Feature Sketching

Yuwen Huang, Xiang Pan

Standard softmax attention scales quadratically with sequence length, which makes long-context training and inference expensive.

We introduce PLASH, an attention block whose cost grows linearly in the number of keys. PLASH compresses the original keys and values into M learned prototypes, where $M\in\mathbb{Z}_{>0}$ is much smaller than the number of keys. The compressed prototypes are then enriched with randomized polynomial features that recover inter-token information lost to compression. The output is computed by exact scaled dot-product softmax attention from each query to the enriched prototypes, so PLASH preserves the standard attention interface.The construction applies to self- and cross-attention. We prove sketch-error bounds for the enrichment step, a per-input certificate that upper-bounds the deviation from standard softmax attention on each forward pass, and a runtime bound linear in the number of queries and keys. Experiments on long-context language modeling (Qwen3-4B on PG-19) and time-series forecasting (ETT, ECL, Weather) show competitive accuracy and favorable scaling against efficient-attention baselines.
****

LC-QAT: Data-Efficient 2-Bit QAT for LLMs via Linear-Constrained Vector Quantization

Haoyu Wang, Xingyu Yu, Haiyan Zhao, Fengxiang Wang, Xu Han

Quantization-aware training (QAT) is essential for extremely low-bit large language models (LLMs). Current QAT methods are mainly based on scalar quantization (SQ), which enables efficient optimization but suffers from severe performance degradation at 2-bit precision.

On the other hand, vector quantization (VQ) provides substantially higher representational capacity, but its discrete codebook lookup prevents end-to-end training.

We propose LC-QAT, a 2-bit weight-only VQ-QAT framework that represents quantized weights via a learned affine mapping over discrete vectors, which yields a high-quality PTQ initialization and enables fully differentiable end-to-end optimization without explicit codebook lookup in the training forward pass.

This strong post-training initialization makes LC-QAT highly data-efficient. Experiments across diverse LLMs demonstrate that LC-QAT consistently outperforms state-of-the-art QAT methods while using only 0.1%–10% of the training data. Our results establish LC-QAT as a practical and scalable solution for extreme low-bit model deployment.

Optimal Regret for Policy Optimization in Contextual Bandits
Orin Levy, Yishay Mansour
We present the first high-probability optimal regret bound for a policy optimiza tion technique applied to the problem of stochastic contextual multi-armed bandi t (CMAB) with general offline function approximation. Our algorithm is both effi cient and achieves an optimal regret bound of $\widetilde{O}(\sqrt{ K|\mathcal{A }|\log|\mathcal{F}|})$, where K is the number of rounds, $\mathcal{A}$ is the set of arms, and $\mathcal{F}$ is the function class used to approximate the los ses.
Our results bridge the gap between theory and practice, demonstrating that the w idely used policy optimization methods for the contextual bandit problem can ach ieve a rigorously-proved optimal regret bound.
We support our theoretical results with an empirical evaluation of our algorithm .
****
Transformed Latent Variable Multi-Output Gaussian Processes
Xiaoyu Jiang, Xinxing Shi, Sokratia Georgaka, Magnus Rattray, Mauricio A Álvarez
Multi-Output Gaussian Processes (MOGPs) provide a principled probabilistic frame work for modelling correlated outputs but face scalability bottlenecks when appl ied to datasets with high-dimensional output spaces. To maintain tractability, e xisting methods typically resort to restrictive assumptions, such as employing l ow-rank or sum-of-separable kernels, which can limit expressiveness. We propose the Transformed Latent Variable MOGP (T-LVMOGP), a novel framework that scales M OGPs to a massive number of outputs while preserving the capacity to capture mea ningful inter-output dependencies. T-LVMOGP constructs a flexible multi-output d eep kernel by mapping inputs and output-specific latent variables into an embedd ing space using a Lipschitz-regularised neural network. Combined with stochastic variational inference, our model effectively scales to high-dimensional output settings. Across diverse benchmarks, including climate modelling with over $10,0 00$ outputs and zero-inflated spatial transcriptomics data, T-LVMOGP outperforms baselines in both predictive accuracy and computational efficiency.
****
Correcting Overparameterization Effects in Fair Empirical Risk Minimization
Xiaoyi MAI, Jean-Michel Loubes
Bias mitigation is particularly challenging for overparameterized machine learni ng (ML) models. Overfitting of training points not only amplifies data bias indu ced by spurious correlations, but also causes the failure of usual bias mitigati on methods. To provide actionable insights to address this challenge, we propos e a precise analysis of fair empirical risk minimization (ERM) in the overparame terized regime. Importantly, we show that even though conventional fair ERM fai ls on overparameterized models, this approach can be corrected by modifying the equality fairness constraint to allow for bias overcompensation. Moreover, our a nalysis presents an empirical criterion for strong equalized odds: balanced grou p-conditional means of representer coefficients, indicating equal average contri bution from each sensitive group. Motivated by this result, we provide an estima ble search interval that localizes the required overcompensation level for balan ced coefficients. Despite the asymptotic nature of our findings, they closely ca pture the statistical behavior of moderately large ML models.
****
MixReasoning: Switching Modes to Think
Haiquan Lu, Gongfan Fang, Xinyin Ma, Qi Li, Xinchao Wang
Reasoning models enhance performance by tackling problems in a step-by-step mann er, decomposing them into sub-problems and exploring long chains of thought befo re producing an answer. However, applying extended reasoning to every step intro duces substantial redundancy, as sub-problems vary widely in difficulty and comp lexity: a small number of pivotal steps are genuinely challenging and decisive f or the final answer, while many others only involve straightforward revisions or simple computations. Therefore, a natural idea is to endow reasoning models wit h the ability to adaptively respond to this variation, rather than treating all steps with the same level of elaboration. To this end, we propose MixReasoning,

a framework that dynamically adjusts the depth of reasoning within a single response. MixReasoning enables fine-grained mode switching by training a lightweight concise LoRA adapter and control its strength to trigger switches based on reasoning difficulty estimated from sliding-window token confidence, yielding human-like transitions between fast and slow reasoning. The resulting chain of thought then becomes a mixture of detailed reasoning on difficult steps and concise inference on simpler ones.
Experiments on AIME24, MATH-500, GPQA, and GSM8K demonstrate that MixReasoning shortens reasoning length by 13\%--49\% across benchmarks of varying difficulty, delivering consistent efficiency gains while maintaining performance.

Efficient Distributed MLLM Training with Cornstarch
Insu Jang, Runyu Lu, Nikhil Bansal, Ang Chen, Mosharaf Chowdhury
Multimodal large language models (MLLMs) extend the capabilities of large language models (LLMs) by combining heterogeneous model architectures to handle diverse modalities like images and audio.
However, this inherent heterogeneity in MLLM model structure and data types makes makeshift extensions to existing LLM training frameworks unsuitable for efficient MLLM training, especially in distributed training.

In this paper, we present Cornstarch, an efficient distributed MLLM training framework that contemplates MLLM's unique characteristics in both model and data parallelization.
Cornstarch introduces frozen-aware pipeline parallelism and workload-balanced context parallelism to improve MLLM training throughput.
Our extensive evaluation shows that Cornstarch outperforms state-of-the-art solutions by $2.26\times$ on average in terms of MLLM training throughput.

Cornstarch is an open-source project and available on [Github](https://github.com/cornstarch-org/Cornstarch).

Predicting What Matters: Robust Generalist Robot Policy Learning via Future Semantic Mask
Yunfan Lou, Xiaowei Chi, Xiaojie Zhang, Zezhong Qian, Chengxuan Li, Rongyu Zhang, Yaoxu Lyu, Guoyu Song, Chuyao Fu, Haoxuan Xu, Pengwei Wang, Shanghang Zhang
World models derived from large-scale video generative pre-training have emerged as a promising paradigm for generalist robot policy learning. However, standard approaches often focus on high-fidelity RGB video prediction, this can result in overfitting to irrelevant factors, such as dynamic backgrounds and illumination changes. These distractions reduce the model's ability to generalize, ultimately leading to unreliable and fragile control policies. To address this, we introduce the Mask World Model (MWM), which leverages video diffusion architectures to predict the evolution of semantic masks instead of pixels. This shift imposes a geometric information bottleneck, forcing the model to capture essential physical dynamics and contact relations while filtering out visual noise. We seamlessly integrate this mask dynamics backbone with a diffusion-based policy head to enable robust end-to-end control. Extensive evaluations demonstrate the superiority of MWM on the LIBERO and RLBench simulation benchmarks, significantly outperforming the state-of-the-art RGB-based world models. Furthermore, real-world experiments and robustness evaluation (via random token pruning) reveal that MWM exhibits superior generalization capabilities and robust resilience to texture information loss.

Decision Tree Learning on Product Spaces
Arshia Soltani Moakhar, Faraz Ghahremani, Kiarash Banihashem, MohammadTaghi Hajiaghayi
Decision tree learning has long been a central topic in theoretical computer science, driven by its practical importance. A fundamental and widely used method for decision tree construction is the top-down greedy heuristic, which recursively splits on the most influential variable. Despite its empirical success, theore

tical analysis of this heuristic has been limited. A recent breakthrough by Blanc et al. (ITCS, 2020) provided the first rigorous theoretical guarantees for the greedy approach, but only under the uniform distribution.
We extend this analysis to the more general and practically relevant setting of arbitrary product distributions.
Our main result shows that for any function f computable by an optimal decision tree of size s, maximum depth D_{opt}, and average depth Δ_{opt}, the greedy heuristic constructs an ϵ-approximating tree whose size grows at most with $\exp(\Delta_{\text{opt}} D_{\text{opt}} \log(e/\epsilon))$.
In the special case where the optimal tree is a full binary tree, this bound improves upon the bound of Blanc et al. and holds under a strictly broader class of distributions. Moreover, we present an algorithm based on the top-down greedy heuristic that is entirely **parameter-free**---it requires no prior knowledge of the optimal tree's size or depth---offering a practical advantage over Blanc et al.'s method.

Gradient Descent with Large Step Size Restores Symmetry in Deep Linear Networks with Multi-Pathway
Hee-Sung Kim, Sungyoon Lee
Recent analyses of multi-pathway Deep Linear Networks use Gradient Flow to predict a "winner-takes-all" specialization in which path symmetry breaks and each feature concentrates in a single pathway.
In this work, we show that discrete Gradient Descent (GD) with a large step size tells a different story.
We prove that single-path solutions are sharp minima, whereas distributing signals across pathways reduces sharpness by a factor that decreases with both the number of pathways and depth.
Consequently, while early training reproduces the depth-driven symmetry breaking predicted by GF, oscillations at the Edge of Stability subsequently override this tendency and drive the network into a re-balancing phase, where signals redistribute across pathways.
Together, these results clarify how depth shapes pathway competition and explain why large-step GD favors shared representations rather than persistent single-pathway dominance.

Accuracy-First Rényi Differential Privacy and Post-Processing Immunity
Ossi Räisä, Antti Koskela, Antti Honkela
The accuracy-first perspective of differential privacy addresses an important shortcoming by allowing a data analyst to adaptively adjust the quantitative privacy bound instead of sticking to a predetermined bound. Existing works on the accuracy-first perspective have neglected an important property of differential privacy known as post-processing immunity, which ensures that an adversary is not able to weaken the privacy guarantee by post-processing. We address this gap by determining which existing definitions in the accuracy-first perspective have post-processing immunity, and which do not. The only definition with post-processing immunity, pure ex-post privacy, lacks useful tools for practical problems, such as an ex-post analogue of the Gaussian mechanism, and an algorithm to check if accuracy on separate private validation set is high enough. To address this, we propose a new definition based on Rényi differential privacy that has post-processing immunity, and we develop basic theory and tools needed for practical applications. We demonstrate the practicality of our theory with applications to synthetic data generation and image classifier fine-tuning, where our algorithm successfully adjusts the privacy bound until an accuracy threshold is met on a private validation dataset.

Reasoning on the Manifold: Bidirectional Consistency for Self-Verification in Diffusion Language Models
Jiaoyang Ruan, Xin Gao, Yinda Chen, Hengyu Zeng, Liang Du, Guanghao Li, Jie Fu, Jian Pu

While Diffusion Large Language Models (dLLMs) offer structural advantages for gl
obal planning, efficiently verifying that they arrive at correct answers via val
id reasoning traces remains a critical challenge. In this work, we propose a geo
metric perspective: Reasoning on the Manifold. We hypothesize that valid generat
ion trajectories reside as stable attractors on the high-density manifold of the
 learned distribution, whereas invalid paths exhibit off-manifold drift. To oper
ationalize this, we introduce Bidirectional Manifold Consistency (BMC), a traini
ng-free, unsupervised metric that quantifies the stability of the generated sequ
ence through a forward-masking and backward-reconstruction cycle. Empirically, w
e demonstrate BMC's versatility across the full reasoning lifecycle: (1) in Diag
nosis, it serves as a robust discriminator of solution validity without ground t
ruth answer; (2) in Inference, it enables rejection resampling to effectively co
ncentrate computational resources on complex reasoning tasks; and (3) in Alignme
nt, it functions as a dense geometric reward that transforms sparse outcome supe
rvision into fine-grained guidance, empowering models to self-evolve beyond stan
dard baselines. Our results establish intrinsic geometric stability as a robust
indicator of correctness for dLLMs.

When Search Goes Wrong: Red-Teaming Web-Augmented Large Language Models
Haoran Ou, Kangjie Chen, Xingshuo Han, Gelei Deng, Jie Zhang, Han Qiu, Tianwei Z
hang, Kwok-Yan Lam
Large Language Models (LLMs) have been augmented with web search to overcome the
 limitations of the static knowledge boundary by accessing up-to-date informatio
n from the open Internet. While this integration enhances model capability, it a
lso introduces a distinct safety threat surface: the retrieval and citation proc
ess has the potential risk of exposing users to harmful or low-credibility web c
ontent. Existing red-teaming methods are largely designed for standalone LLMs as
 they primarily focus on unsafe generation, ignoring risks emerging from the com
plex search workflow.
To address this gap, we propose CREST-Search, a pioneering red-teaming framework
 for LLMs with web search. The cornerstone of CREST-Search is three novel attack
 strategies that generate seemingly benign search queries yet induce unsafe cita
tions. It also employs an iterative in-context refinement mechanism to strengthe
n adversarial effectiveness under black-box constraints.
In addition, we construct a search-specific harmful dataset, WebSearch-Harm, whi
ch enables fine-tuning a specialized red-teaming model to improve query quality.
 Our experiments demonstrate that CREST-Search can effectively bypass safety fil
ters and systematically expose vulnerabilities in web search-based LLM systems,
underscoring the necessity of the development of robust search models.

Hyperbolic Neural Operator
Jieyuan Pei, Zhuoxuan Li, Wei Li, Haobo Zhang, jiawei jiang, Jianwei Zheng
Neural operators have emerged as powerful surrogates for solving PDEs, significa
ntly accelerating scientific computation.
While transformer-based architectures offer unmatched flexibility for irregular
domains, they suffer from a fundamental efficiency gap: standard attention mecha
nisms assign uniform interaction budgets to all token pairs, neglecting the phys
ical reality that far-field interactions are often compressible.
To address this mismatch, we draw inspiration from classical fast solvers that e
xploit hierarchical near-far decompositions. We further observe that embedding s
uch tree-structured hierarchies in Euclidean space incurs inherent distortion, w
hereas hyperbolic space naturally accommodates exponential branching.
Consequently, we propose \textbf{Hyperbolic Neural Operator (HNO)}, which levera
ges intrinsic hyperbolic geometry to instantiate a continuous Gibbs kernel based
 on stabilized geodesic distances on the Lorentz hyperboloid. This design impose
s a geometric inductive bias that naturally enjoys robust multi-scale routing ak
in to the Fast Multipole Method (FMM), yet within a unified, learnable attention
 mechanism.
Empirically, HNO achieves state-of-the-art accuracy on six PDE benchmarks and tw
o large-scale unstructured CFD tasks, reducing the mean relative ℓ_2 error

by up to 40\% compared to leading baselines. Codes are attached and will be avai
lable online.

From Bits to Rounds: Parallel Decoding with Exploration for Diffusion Language M
odels
Hengyu Fu, Baihe Huang, Virginia Adams, Charles Wang, Junkeun Yi, Mohammad Mahdi
 Kamani, Venkat Krishna Srinivasan, Jiantao Jiao
Diffusion Language Models (DLMs) have recently emerged as a strong alternative t
o autoregressive language models (AR-LMs), due to their comparable accuracy and
faster inference speed via parallel decoding.
However, standard DLM decoding strategies, which rely on unmasking only high-con
fidence tokens, encounter an inherent information-theoretic bottleneck that rest
ricts decoding progress and ultimately slows down generation.
We demonstrate this through an information-theoretic lower bound that the number
 of decoding rounds must grow linearly with the sample's total information and i
nversely with the per-round information budget, establishing a bits-to-rounds pr
inciple.
Motivated by this theory, we propose Explore-Then-Exploit (ETE), a training-free
 decoding strategy that maximizes information throughput and decoding efficiency
. ETE combines cross-block decoding with targeted exploration of high-uncertaint
y tokens to reshape the conditional distribution and trigger cascades of confide
nt predictions.
Experiments across diverse benchmarks verify our theoretical bounds and demonstr
ate that ETE consistently reduces the number of decoding rounds compared to conf
idence-only baselines without compromising generation quality.
Furthermore, ETE integrates efficiently with KV caching, translating these algor
ithmic gains into improved tokens-per-second throughput.

Deep sequence models tend to memorize geometrically; it is unclear why
Shahriar Noroozizadeh, Vaishnavh Nagarajan, Elan Rosenfeld, Sanjiv Kumar
Deep sequence models are said to store atomic facts predominantly in the form of
 associative memory: a brute-force lookup of co-occurring entities. We identif
y a dramatically different form of storage of atomic facts that we term as *geom
etric* memory. Here, the model has synthesized embeddings encoding novel *global
* relationships between all entities, including ones that do not co-occur in tra
ining. Such storage is powerful: for instance, we show how it transforms a hard
 reasoning task involving an ℓ-fold composition into an easy-to-learn 1-s
tep navigation task.

From this phenomenon, we extract fundamental aspects of neural embedding geometr
ies that are hard to explain. We argue that
the rise of such a geometry, as against a lookup of local associations, cannot b
e straightforwardly attributed to typical supervisory, architectural, or optimiz
ational pressures. Counterintuitively, a geometry is learned even when it is mor
e complex than the brute-force lookup.

Then, by analyzing a connection to Node2Vec, we demonstrate how the geometry ste
ms from a spectral bias that—in contrast to prevailing theories—indeed arises na
turally despite the lack of various pressures. This analysis also points out to
practitioners a visible headroom to make Transformer memory more strongly geomet
ric. We hope the geometric view of parametric memory encourages revisiting the d
efault intuitions that guide researchers in areas like knowledge acquisition, ca
pacity, discovery, and unlearning.

Beyond Fixed Biases: Decoding the Role of Reasoning Uncertainty in MLLM Modality
 Conflicts
Zhuoran Zhang, Tengyue Wang, Xilin Gong, Yang Shi, Haotian Wang, Di Wang, Lijie
Hu
Multimodal Large Language Models (MLLMs) must resolve conflicts when modalities
provide contradictory information, a behavior we term "modality following". We p

ropose a framework that decomposes this behavior into case-specific relative pre ference uncertainty and stable inherent preference. Across diverse MLLMs and ben chmarks, the probability of following a modality consistently decreases as its r elative preference uncertainty increases, a trend robust to alternative uncertai nty indices. This regularity defines a "balance point'' where modality preferenc es are evenly matched, offering a capability-disentangled measure of modality bi as. Layer-wise probing further shows that ambiguous cases near the balance point trigger middle-to-late-layer "concept oscillations," where top predictions vaci llate between modality-supported answers. Finally, we demonstrate the framework' s utility for preference steering through Supervised Fine-Tuning (SFT). We find that data efficiency is governed by preference uncertainty: training on easy sam ples (where one modality dominates) fails to generalize, whereas targeting the i dentified ``boundary cases" is essential for robust preference alignment and sup pressing internal vacillation.

SpecForge: A Flexible and Efficient Open-Source Training Framework for Speculati ve Decoding

Shenggui Li, Chao Wang, YIKAI ZHU, Yubo Wang, Fan Yin, Shuai Shi, Yefei Chen, Xi aomin Dong, Qiaoling Chen, Jin Pan, Ji Li, Yineng Zhang, Lei Yu, Yonggang Wen, I vor Tsang, Tianwei Zhang

Speculative decoding mitigates the memory-bound nature of LLM decoding by using a lightweight draft model to propose multiple tokens for parallel verification. However, its adoption has been limited by the lack of high-quality draft models and scalable training infrastructure. We introduce SpecForge, an open-source and efficient framework for training speculative decoding models with full support for EAGLE-3. SpecForge incorporates target–draft decoupling, hybrid parallelism, optimized training kernels, and tight integration with production-grade inferen ce engines, enabling up to 9.9x faster EAGLE-3 training for Qwen3-235B-A22B comp ared to the baseline. We further release SpecBundle, a suite of production-grade EAGLE-3 draft models trained with SpecForge for mainstream open-source LLMs, ac hieving up to 4.48x end-to-end inference speedup on SGLang and addressing the sc arcity of high-quality drafts. Finally, we distill a systematic study of specula tive decoding training into practical and actionable recipes to guide real-world adoption.

SkillNet: Hierarchical Skill Modeling for Compositional Generalization in Vision -Language Action Models

Senwei Xie, Yuntian Zhang, Zhenzhou Tan, Ruiping Wang, Pengwei Wang, Shanghang Z hang, Xilin CHEN

Transfer across diverse task compositions and unseen behaviors remains a signifi cant challenge for vision-language action (VLA) models. Skills are repeatable an d atomic components for various tasks, and similarities shared with different sk ills provide evidence for transferability across behaviors. However, existing sk ill-centric methods have two problems. First, skills are often loosely organized , lacking a hierarchy that can capture similarities and differences across skill s. Second, they lack a mechanism which has the capacity to express transferable skill attributes in a structured parametric space. To this end, we propose Skill Net, which models skill attributes in a hierarchical way and regulates compositi onal model structure with transferable skill attributes. SkillNet exploits motio n code and VerbNet Framework to explicitly model similarities of skills on mecha nical properties and semantic roles, and organizes skills in a hierarchical way. Based on this hierarchy, SkillNet leverages the scalability of the mixture-of-e xperts (MoE) mechanism and develops skill embeddings as soft constraints to enab le compositional generalization via similar expert activations on similar skills . On zero-shot and few-shot transfer experiments in simulators and real-world en vironments, SkillNet achieves an improvement of performance by 16.0% and 23.9%. Meanwhile, SkillNet achieves state-of-the-art performance on in-domain settings.

Retro-Expert: Collaborative Reasoning for Interpretable Retrosynthesis

Xinyi Li, Sai Wang, Yutian Lin, Yu Wu

Retrosynthesis prediction aims to infer the reactant molecules based on a given product molecule, which is a fundamental task in chemical synthesis. However, existing methods rely on a static pattern-matching paradigm, which limits their ability to perform effective logical decision-making from chemical data, leading to a black-box process. We propose Retro-Expert, an interpretable retrosynthesis framework that performs collaborative reasoning by combining the complementary strengths of Large Language Models and specialized models via pure reinforcement learning. It outputs natural language explanations grounded in chemical logic through three components: (1) specialized models provide chemical knowledge that is distilled into a high-quality chemical decision space, (2) LLM-driven critical reasoning to generate predictions with an interpretable reasoning path, and (3) knowledge-grounded policy optimization refines the interpretable decision policy. Experiments show that Retro-Expert surpasses both LLM-based and specialized models across different metrics, while generating chemically grounded explanations that enhance chemists' trust in practice. The source code for this paper is available at https://github.com/MagixRab-ll/Retro-Expert

Experience is the Best Teacher: Motivating Effective Exploration in Reinforcement Learning for LLMs

Wenjian Zhang, Kongcheng Zhang, Jiaxin Qi, Jianqiang Huang, Baisheng Lai

Reinforcement Learning (RL) with rubric-based rewards has recently shown remarkable progress in enhancing general reasoning capabilities of Large Language Models (LLMs), yet still suffers from ineffective exploration confined to current policy distribution. In fact, RL optimization can be viewed as steering the policy toward an ideal distribution that maximizes the rewards, while effective exploration should align efforts with desired target. Leveraging this insight, we propose HeRL, a ****H***indsight ***e***xperience guided ***R***einforcement ***L***earning* framework to bootstrap effective exploration by explicitly *telling LLMs the desired behaviors* specified in rewards. Concretely, HeRL treats failed attempts along with their unmet rubrics as hindsight experience, which serves as in-context guidance for the policy to explore desired responses beyond its current distribution. Additionally, we introduce a bonus reward to incentivize responses with greater potential for improvement under such guidance. HeRL facilitates effective learning from desired high-quality samples without repeated trial-and-error from scratch, yielding a more accurate estimation of the expected gradient theoretically. Extensive experiments across various benchmarks demonstrate that HeRL achieves superior performance gains over baselines, and can further benefit from experience guided self-improvement at test time.

H^{2}CL: Heterogeneity-Aware Hypergraph Contrastive Learning for Robust Representation Learning

Kaixuan Yao, Ting Guo, Feilong Cao, Ming Li

Hypergraph contrastive learning has shown strong potential for modeling high-order relations, but most existing methods implicitly assume that nodes within the same hyperedge are semantically homogeneous. In real-world hypergraphs, this assumption often breaks down: heterogeneous node--hyperedge interactions may introduce noisy signals during augmentation and message passing, leading to feature contamination and false-positive contrastive alignment. To address this issue, we propose H^{2}CL, a heterogeneity-aware hypergraph contrastive learning framework for robust representation learning. H^{2}CL first estimates node--hyperedge heterogeneity from input features and uses it to guide a Heterogeneity-Aware View Generator, which selectively masks high-heterogeneity incidences and constructs cleaner contrastive views. It further introduces a Heterogeneity-Aware Hypergraph Encoder that dynamically reweights information propagation in both node-to-hyperedge and hyperedge-to-node aggregation, enabling hyperedges to aggregate more homogeneous signals while suppressing heterogeneous noise. We also provide theoretical analysis showing that the encoder corresponds to a coordinate descent step for minimizing a heterogeneity-weighted Dirichlet energy. Extensive experiments on standard benchmarks and larger-scale hypergraphs demonstrate that H^{2}CL achieves competitive or superior performance compared with recent baselines, remai

ns robust under structural noise, and learns reweighting patterns that effectively reduce heterogeneity during message passing. Our code is available at: https://github.com/sxu-yaokx/HHCL

Tighter Regret Lower Bound for Gaussian Process Bandits with Squared Exponential Kernel in Hypersphere

Shogo Iwazaki

We study an algorithm-independent, worst-case lower bound for the Gaussian process (GP) bandit problem in the frequentist setting, where the reward function is fixed and has a bounded norm in the known reproducing kernel Hilbert space (RKHS). Specifically, we focus on the squared exponential (SE) kernel, one of the most widely used kernel functions in GP bandits. One of the remaining open questions for this problem is the gap in the *dimension-dependent* logarithmic factors between upper and lower bounds. This paper partially resolves this open question under a hyperspherical input domain. We show that any algorithm suffers $\Omega(\sqrt{T (\ln T)^{d} (\ln \ln T)^{-d}})$ cumulative regret, where T and d represent the total number of steps and the dimension of the hyperspherical domain, respectively. Regarding the simple regret, we show that any algorithm requires $\Omega(\epsilon^{-2}(\ln \frac{1}{\epsilon})^d (\ln \ln \frac{1}{\epsilon})^{-d})$ time steps to find an ϵ-optimal point. We also provide the improved $O((\ln T)^{d+1}(\ln \ln T)^{-d})$ upper bound on the maximum information gain for the SE kernel. Our results guarantee the optimality of the existing best algorithm up to *dimension-independent* logarithmic factors under a hyperspherical input domain.

QuantumBoost: A lazy, yet fast, quantum algorithm for learning with weak hypotheses

Amira Abbas, Yanlin Chen, Tuyen Quang Nguyen, Ronald de Wolf

The technique of combining multiple votes to enhance the quality of a decision is the core of boosting algorithms in machine learning. In particular, boosting provably increases decision quality by combining multiple "weak learners"—hypotheses that are only slightly better than random guessing—into a single "strong learner" that classifies data well. There exist various versions of boosting algorithms, which we improve upon through the introduction of QuantumBoost. Inspired by classical work by Barak, Hardt and Kale, our QuantumBoost algorithm achieves the best known runtime over other boosting methods through two innovations. First, it uses a quantum algorithm to compute approximate Bregman projections faster. Second, it combines this with a lazy projection strategy, a technique from convex optimization where projections are performed infrequently rather than every iteration. To our knowledge, QuantumBoost is the first algorithm, classical or quantum, to successfully adopt a lazy projection strategy in the context of boosting.

Sampling from Your Language Model One Byte at a Time

Jonathan Hayase, Alisa Liu, Noah A. Smith, Sewoong Oh

Tokenization is used almost universally by modern language models, enabling efficient text representation using multi-byte or multi-character tokens. However, prior work has shown that tokenization can introduce distortion into the model's generations, an issue known as the Prompt Boundary Problem (PBP). For example, users are often advised not to end their prompts with a space because it prevents the model from including the space as part of the next token. While this heuristic is effective in English, the underlying PBP continues to affect code generation and languages such as Chinese, where tokens often do not line up with word and syntactic boundaries. In this work, we present an inference-time method to convert any autoregressive LM with a BPE tokenizer into a character-level or byte-level LM. Our method efficiently solves the PBP and is also able to unify the vocabularies of language models with different tokenizers, allowing one to ensemble LMs with different tokenizers at inference time or transfer the post-training from one model to another using proxy-tuning.

Flex-Forcing: Towards a Unified Autoregressive and Bidirectional Video Diffusion Model

Xinyin Ma, Julius Berner, Chao Liu, Arash Vahdat, Weili Nie, Xinchao Wang

Recent progress in large-scale generative models has substantially advanced video generation, yet existing methods remain constrained by a rigid inference paradigm. Bidirectional diffusion models excel at global coherence and visual fidelity but suffer from slow inference, while autoregressive models offer efficient and streaming generation at the cost of long-range consistency and exposure bias. We introduce Flex-Forcing, a unified training and inference framework that enables a video diffusion model to seamlessly operate under both bidirectional and autoregressive generation regimes. The core idea is a flexible chunking mechanism jointly defined over the temporal axis and denoising steps. This design allows the model to (1) perform flexible chunking according to different device budgets, (2) perform bidirectional inference across chunks for global structure planning, while generating frames autoregressively within each chunk for efficient and fine-grained synthesis, and (3) perform any-order, any-timestep autoregressive generation without the strict causal constraint. Extensive experiments on multiple video generation benchmarks demonstrate that Flex-Forcing achieves consistently better video quality, long-video stability than strong baselines with a rigid inference schedule, while offering faster inference.

OSM+: Billion-Level Open Street Map Dataset for City-wide Experiments

Guanjie Zheng, Ziyang Su, Yiheng Wang, Yuhang Luo, Hongwei Zhang, Xuanhe Zhou, Linghe Kong, Fan Wu, Wen Ling

Road network data provides rich information about cities, but processing worldwide OpenStreetMap (OSM) data is computationally intensive, and the resulting graphs are often difficult to unify for benchmarking downstream tasks. Existing graph learning benchmarks fail to capture the billion-scale and unique topological properties of real-world road networks, leaving model scalability underexplored. To close this gap, we process OSM data with distributed cloud computing using 5,000 cores and release **OSM+**, a structured worldwide 1-billion-vertex road network graph dataset designed for high accessibility and usability. OSM+ is open source and globally downloadable, providing an open-box graph structure together with an easy spatial query interface that allows users to retrieve, inspect, and integrate road network topology, geometry, and attributes without repeatedly preprocessing raw OSM files. We demonstrate the utility of OSM+ through four illustrative use cases: basic query, city boundary detection, traffic prediction, and traffic policy control. For traffic prediction, we construct a new 31-city benchmark by processing traffic data and combining it with OSM+, enabling broader spatial coverage and more comprehensive evaluation than commonly used datasets, while scaling from hundreds of road network intersections to thousands. For traffic policy control, we release a new six-city dataset at a much larger scale, introducing challenges for thousand-scale multi-agent coordination and controller scalability. We also provide data processing tools for integrating multimodal spatial-temporal data with OSM+ for geospatial foundation model training, thereby expediting the discovery of compelling scientific insights.

Global Directional Priors with Local Statistical Validation for Scalable Causal Discovery

Wei Yuan, Zixuan Shao, Shuhui Wang

Constraint-based causal discovery relies on conditional independence (CI) tests whose reliability degrades as conditioning sets grow, particularly in hub-dominated graphs. Existing methods constrain adjacency or global structure, but leave conditioning-set dimensionality uncontrolled. In this paper, we propose Ordering-Constrained Markov Blanket discovery (OCMB), a paradigm that treats conditioning-set dimensionality as a first-class constraint. OCMB decouples discovery into two stages: lightweight global ordering estimation providing directional priors, followed by local Markov blanket validation within small, ordering-constrained candidate sets. By enforcing directional constraints before any CI test, OCMB ensures bounded conditioning sets even with hub nodes. We show that OCMB recovers

correct parent sets provided a high-recall ordering assumption holds, without re
quiring the ordering to be globally correct. Experiments demonstrate that OCMB s
ignificantly improves precision and robustness over constraint-based and hybrid
methods in high-dimensional regimes where conventional CI-based approaches fail.
****

MAD: Manifold Attracted Diffusion

Dennis Elbrächter, Giovanni S Alberti, Matteo Santacesaria

Score-based diffusion models are a highly effective method for generating sample
s from a distribution of images. We consider scenarios where the training data c
omes from a noisy version of the target distribution, and present an efficiently
 implementable modification of the inference procedure to generate noiseless sam
ples. Our approach is motivated by the manifold hypothesis, according to which m
eaningful data is concentrated around some low-dimensional manifold of a high-di
mensional ambient space. The central idea is that noise manifests as low magnitu
de variation in off-manifold directions in contrast to the relevant variation of
 the desired distribution which is mostly confined to on-manifold directions. We
 introduce the notion of an extended score and show that, in a simplified settin
g, it can be used to reduce small variations to zero, while leaving large variat
ions mostly unchanged. We describe how its approximation can be computed efficie
ntly from an approximation to the standard score and demonstrate its efficacy on
 toy problems, synthetic data, and real data.

Preconditioning Neural Tangent Kernel for Adaptive Optimization

Xiyuan Yang, Wenxuan Bao, Katherine Tieu, Jingrui He

The Neural Tangent Kernel is a theoretical framework for understanding the train
ing dynamics of neural networks. However, standard NTK and its variants fail to
properly depict the finetuning of foundation models, as they neglect the precond
itioning effects of adaptive gradients.

To bridge this gap, we propose the Optimizer Aware Kernel (OAK), which incorpora
tes the optimizer's influence into standard NTK framework by a preconditioner es
timation technique. Furthermore, we conduct an analysis to answer: when and why
kernel regime fails in finetuning. We derive explicit error bounds showing that
the collapse of kernel regime is primarily due to the cumulative training effect
s and the task discrepancy between pretraining and finetuning. Theoretically, we
 justify OAK's preconditioner estimation by bounding its error term. Empirically
, experiments on various model architectures show both the effectiveness of the
OAK method and validity of our arguments on kernel regime collapse.

MVISTA-4D: View-Consistent 4D World Model with Test-Time Action Inference for Ro
botic Manipulation

Jiaxu Wang, JIANG Yicheng, Tianlun HE, Jingkai SUN, Qiang Zhang, Jiahang Cao, Ze
sen Gan, Mingyuan Sun, Qiming Shao, Xiangyu Yue

World-model-based imagine-then-act becomes a promising paradigm for robotic mani
pulation, yet existing approaches typically support either purely image-based fo
recasting or reasoning over partial 3D geometry, limiting their ability to predi
ct complete 4D scene dynamics. To solve this, this work explores a novel embodie
d 4D world model that enables geometrically consistent, arbitrary-view RGBD gene
ration: given only a single-view RGBD observation as input, the model “imagines”
 the remaining viewpoints, which can then be back-projected and fused to assembl
e a more complete 3D structure across time. To efficiently learn the multi-view,
 cross-modality generation, we explicitly design cross-view and cross-modality f
eature fusion that jointly encourage consistency between RGB and depth and enfor
ce geometric alignment across views. Beyond prediction, converting generated fut
ures into actions is often handled by inverse dynamics, which is ill-posed becau
se multiple actions can explain the same transition. We address this with a test
-time action optimization strategy that backpropagates through the generative mo
del to infer a trajectory-level latent best matching the predicted future, and a
 residual inverse dynamics model that turns this trajectory prior into accurate
executable actions. Extensive experiments on the three datasets and platforms de
monstrate strong performance on both 4D scene generation and downstream manipula

tion, and ablations provide practical insights into the key design choices. Proj
ect page is available at \url{https://mercerai.github.io/MVISTA-4D/}.
****
Normalization Equivariance for Arbitrary Backbones, with Application to Image De
noising
Youssef Saied, François Fleuret
Normalization Equivariance (NE) is a structural prior that improves robustness t
o distribution shift in image-to-image tasks.
A function f is normalization equivariant iff $f(a y + b\mathbf{1}) = a f(y) +
 b\mathbf{1}$ for all $a>0$ and $b\in\mathbb{R}$.
Existing NE methods constrain every internal layer to NE-compatible operations.
These constraints add runtime cost and exclude standard transformer components s
uch as softmax attention and LayerNorm.
We introduce Wrapped Normalization Equivariance (WNE), a parameter-free wrapper
that normalizes the input, applies any backbone, and denormalizes the output.
We prove every NE function admits this factorization, so the wrapper exactly par
ameterizes the class of NE functions.
On blind denoising, wrapping CNN and transformer architectures improves robustne
ss under noise-level mismatch with no measurable GPU overhead, while architectur
al NE baselines are up to $1.6\times$ slower.
****
Rectified LpJEPA: Joint-Embedding Predictive Architectures with Sparse and Maxim
um-Entropy Representations
Yilun Kuang, Yash Dagade, Tim G. J. Rudner, Randall Balestriero, Yann LeCun
Joint-Embedding Predictive Architectures (JEPA) learn view-invariant representat
ions and admit projection-based distribution matching for collapse prevention. E
xisting approaches regularize representations towards isotropic Gaussian distrib
utions, but inherently favor dense representations and fail to capture the key p
roperty of sparsity observed in efficient representations. We introduce Rectifie
d Distribution Matching Regularization (RDMReg), a sliced two-sample distributio
n-matching loss that aligns representations to a Rectified Generalized Gaussian
(RGG) distribution. RGG enables explicit control over expected ℓ_0 norm thr
ough rectification, while its continuous truncated component admits a maximum-en
tropy characterization under expected ℓ_p norm and support constraints. Equ
ipping JEPAs with RDMReg yields Rectified LpJEPA, which strictly generalizes pri
or Gaussian-based JEPAs. Empirically, Rectified LpJEPA learns sparse, non-negati
ve representations with favorable sparsity--performance trade-offs and competiti
ve downstream performance on image classification benchmarks, showing that RDMRe
g can enforce sparsity while preserving task-relevant information.

AutoTool: Dynamic Tool Selection and Integration for Agentic Reasoning
Jiaru Zou, Ling Yang, Yunzhe Qi, Sirui Chen, Mengting Ai, Ke Shen, Jingrui He, M
engdi Wang
Agentic reinforcement learning has advanced large language models (LLMs) to reas
on through long chain-of-thought trajectories while interleaving external tool u
se. Existing approaches assume a fixed inventory of tools, which limits the adap
tability of LLM agents to new or evolving toolsets. We present AutoTool, a train
ing framework that equips LLM agents with dynamic tool-selection capabilities th
roughout their reasoning trajectories. AutoTool employs a dual-phase optimizatio
n pipeline: (i) SFT and RL-based trajectory stabilization for coherent reasoning
, and (ii) KL-regularized Plackett–Luce Ranking to refine consistent multi-step
tool selection.
We further build a 200k dataset with explicit tool-selection rationales across 1
,000+ tools and 100+ tasks spanning mathematics, science, code generation, and m
ultimodal reasoning. Across ten diverse benchmarks, we train two base models, Qw
en3-8B and Qwen2.5-VL-7B, with AutoTool. With fewer parameters, AutoTool consist
ently outperforms advanced LLM agents and tool-integration methods, yielding ave
rage gains of 6.4\% in math \& science reasoning, 4.5\% in search-based QA, 7.7\
% in code generation, and 6.9\% in multimodal understanding. In addition, AutoTo
ol exhibits stronger generalization by dynamically leveraging unseen tools from

evolving toolsets during inference.

Sharpness-Aware Pretraining Mitigates Catastrophic Forgetting
Ishaan Watts, Catherine Li, Sachin Goyal, Jacob Mitchell Springer, Aditi Raghunathan
Pretraining optimizers are tuned to produce the strongest possible base model, on the assumption that a stronger starting point yields a stronger model after subsequent changes like post-training and quantization. This overlooks the geometry of the base model which controls how much of the base model's capabilities survive subsequent parameter updates. We study three pretraining optimization approaches that bias optimization toward flatter minima: Sharpness-Aware Minimization (SAM), large learning rates, and shortened learning rate annealing periods. Across model sizes ranging from 20M to 150M parameters, we find that these interventions consistently improve downstream performance after post-training on five common datasets with up to 80\% less forgetting. These principles hold at scale: a short SAM mid-training phase applied to an existing OLMo-2-1B checkpoint reduces forgetting by 31\% after MetaMath post-training and by 40\% after 4-bit quantization.
****
SpatioLM: Towards General Physical Spatial Intelligence in Vision-Language Models
jing wu, Jianhua Wu, Jiayi Guan, Jiahong Chen, Jinghui Lu, Hangjun Ye, Bingzhao Gao, Long Chen
Vision-Language Models (VLMs) perform well on commonsense reasoning tasks but struggle with visual spatial reasoning. Most existing solutions introduce extra 3D prior inputs or external spatial encoders, which increase complexity and degrade the underlying VLMs' general-purpose capabilities after spatial fine-tuning. To this end, we propose a parameter-efficient \textit{\textbf{Spatio}-vision \textbf{L}anguage \textbf{M}odels (SpatioLM)}, that enhances spatial intelligence without extra 3D prior inputs or third-party spatial encoders. Concretely, we design a plug-and-play and non-invasive spatio-vision module that elicits the spatial knowledge inherent in VLMs. Furthermore, we innovatively leverage pseudo depth and camera information as supervision to guide the model in learning physically coherent representations. Extensive experiments show that SpatioLM achieves significant improvements in diverse tasks, including spatial perception and understanding while effectively limiting the degradation of general capabilities. Notably, the model achieves an impressive score of 71.6 on the VSI-Bench (the first model to surpass 70). In addition, it attains competitive performance when transferred to embodied manipulation tasks.
****
Solving Imperfect-Recall Games via Sum-of-Squares Optimization
Rui Zheng, Ryann Sim, Antonios Varvitsiotis
Extensive-form games (EFGs) provide a powerful framework for modeling sequential decision making, capturing strategic interaction under imperfect information, chance events, and temporal structure. Most positive algorithmic and theoretical results for EFGs assume perfect recall, where players remember all past information and actions. We study the increasingly relevant setting of imperfect-recall EFGs (IREFGs), where players may forget parts of their history or previously acquired information, and where equilibrium computation is provably hard. We propose sum-of-squares (SOS) hierarchies for computing ex-ante optimal strategies in single-player IREFGs and Nash equilibria in multi-player IREFGs, working over behavioral strategies. Our theoretical results show that (i) these hierarchies converge asymptotically, (ii) under genericity assumptions, the convergence is finite, and (iii) in single-player non-absentminded IREFGs, convergence occurs at a finite level determined by the number of information sets. Finally, we introduce the new classes of (SOS)-concave and (SOS)-monotone IREFGs, and show that in the single-player setting the SOS hierarchy converges at the first level, enabling equilibrium computation with a single semidefinite program (SDP).

Multi-Objective Protein Design via Memory-Aware Test-Time Scaling in Diffusion M

odels
Ming Yang, Xin Zheng, Yi Li, YIZHEN ZHENG, Huan Yee Koh, Yanqing Guo, Xiaofeng C ao, Shirui Pan
Multi-objective protein design is essential for meeting the complex demands of s ynthetic biology. To adapt to shifting multi-functional targets without the proh ibitive cost of retraining, test-time scaling has emerged as a flexible, trainin g-free alternative. However, current test-time diffusion methods face critical challenges: i) ineffective learning from interaction history leading to repetiti ve design errors, ii) over-reliance on successful cases as the reward signal, an d iii) difficulties in balancing multi-objective functional trade-offs . To addr ess these limitations, we propose MoMST, a framework for Multi-objective protein design via Memory-aware Self-contrastive learning with Test-time scaling in dif fusion models. At test time, we develop a memory bank to extract generalizable r easoning experience from historical iterations. Building on this powerful experi ence learner, we derive rich residue-level relative preference signals from both successful and failed cases via self-contrastive learning for guiding protein g eneration. To ensure balance among competing multi-objective functions, we prese nt an inference-time Pareto alignment strategy to resolve objective conflicts. E valuations on both single-objective and complex multi-objective tasks demonstrat e the remarkable performance of MoMST, with code available at https://github.com /MingYangi/MoMST.

KernelCraft: Benchmarking for Agentic Close-to-Metal Kernel Generation on Emergi ng Hardware
Jiayi Nie, Haoran Wu, Yao Lai, Zeyu Cao, Cheng Zhang, Binglei Lou, Erwei Wang, J ianyi Cheng, Timothy M. Jones, Robert D. Mullins, Rika Antonova, Yiren Zhao
New AI accelerators with novel instruction set architectures (ISAs) often requir e developers to manually craft low-level kernels — a time-consuming and error-pr one process that does not scale across hardware targets. This delays emerging ha rdware platforms from reaching the market. While prior LLM-based code generation has shown promise in mature GPU ecosystems, it remains unclear whether agentic LLM systems can quickly produce valid and efficient kernels for emerging hardwar e with new ISAs. We present KernelCraft: the first benchmark for evaluating an L LM agent's ability to generate and optimize low-level kernels for customized acc elerators through a function-calling, feedback-driven workflow. We evaluate agen t performance across three emerging accelerators on more than 20 machine-learnin g tasks, each with five diverse task configurations. Across four leading reasoni ng models, the strongest agents generate functionally correct kernels for unseen ISAs within a few refinement steps, and produce optimized kernels that match or outperform compiler baselines. These results demonstrate KernelCraft's potentia l to accelerate the accelerator chip development cycle. KernelCraft is available at https://kernelcraft-cam.github.io/.

Inverse Depth Scaling From Most Layers Being Similar
Yizhou Liu, Sara Kangaslahti, Ziming Liu, Jeff Gore
Neural scaling laws relate loss to model size in large language models (LLMs), y et depth and width may contribute to performance differently, requiring more det ailed studies. Here, we quantify how depth affects loss via analysis of LLMs and toy residual networks. We find loss scales inversely proportional to depth in L LMs, probably due to functionally similar layers reducing error through ensemble averaging rather than compositional learning or discretizing smooth dynamics. T his regime is inefficient yet robust and may arise from the architectural bias o f residual networks and target functions incompatible with smooth dynamics. The findings suggest that improving LLM efficiency may require architectural innovat ions to encourage compositional use of depth.

Future-Gain Guided Test-Time Learning for Large Language Models
LangYu Bian, Jinwu Hu, Zitian Zhang, Dongjin Yang, Yufeng Wang, Qing Du, Qi Chen , Mingkui Tan
Large language models (LLMs) inevitably encounter distribution shifts during rea

l-world deployment, leading to performance degradation. Although test-time learn ing (TTL) adapts LLMs from unlabeled test streams, applying entropy minimization to autoregressive generation faces two challenges: (i) early decoding errors ca n steer later tokens off track, and updating on them can push the model further off course, and (ii) updates on unreliable tokens can amplify confident error pr edictions and trigger model collapse. To address these challenges, we propose Fu ture-Gain Guided Test-Time Learning (FG-TTL) for LLMs, which learns selectively from the model's own generations. Our key idea is to update only on tokens that reduce uncertainty in subsequent generation rather than tokens that are merely u ncertain at the current step. Specifically, we develop a Future-Gain Guided Toke n Selection (FTS) strategy to decide where to learn. We introduce Future-Gain as a token-level metric for this purpose and update the model only on high-gain to kens, concentrating learning on informative positions and mitigating temporal er ror propagation. In addition, we design a Risk-Aware Adaptation (RAA) mechanism that controls how strongly to update by combining gain-based weighting with adap tive temperature scaling based on intrinsic uncertainty, suppressing unreliable gradients while enabling stronger learning on high-gain tokens. Experiments on s ix benchmarks with three LLM backbones show that FG-TTL achieves the best averag e performance.

Selective Deferred Routing: Enabling Cost-Efficient Collaboration between Local SLMs and Remote LLMs

Qijun Miao, Zhixuan Fang

The rapid advancement of large language models (LLMs) has led to remarkable perf ormance across diverse domains, making them indispensable assistants in daily li fe and work. Currently, LLM services are primarily accessed in two ways: (i) pai d access to cloud-hosted LLMs, which are powerful but introduce nontrivial cost; and (ii) deployment of small language models (SLMs) on personal devices or smal l clusters, which, while less powerful, are sufficient for handling relatively s imple tasks. To achieve a balanced trade-off between monetary cost and task perf ormance, we propose Selective Deferred Routing, a paradigm that enables cost-eff icient collaboration between local SLMs and remote LLMs. In this framework, a us er request is first processed by the local SLM, which not only generates a preli minary response but also provides rich semantic representations of the request. A lightweight decision module then leverages this information to either adopt th e initial response or route the request to the most suitable remote LLM for a hi gher-quality response. Extensive experiments across diverse model architectures and families, including both SLMs and LLMs, as well as datasets spanning multipl e task scenarios, demonstrate that our approach consistently outperforms existin g multi-LLM collaboration methods under a wide range of cost–performance trade-o ffs.

Multiple Choice Learning of Low-Rank Adapters for Language Modeling

Victor Letzelter, Hugo Malard, Mathieu Fontaine, Gaël Richard, Slim Essid, Andre i Bursuc, Patrick Perez

We propose LoRA-MCL, a training scheme that extends next-token prediction in lan guage models with a method designed to decode diverse, plausible sentence contin uations at inference time. Traditional language modeling is an intrinsically ill -posed problem: given a context, multiple ``futures'' may be equally plausible. Our approach leverages Multiple Choice Learning (MCL) and the winner-takes-all l oss to efficiently handle ambiguity through Low-Rank Adaptation. We provide a th eoretical interpretation of applying MCL to language modeling, assuming the data is generated from a mixture of distributions. We illustrate the proposed approa ch using mixtures of Markov chains. We then demonstrate with experiments on audi o and visual captioning, as well as machine translation, that our method achieve s high diversity and relevance in generated outputs. We release the code for app lying LoRA-MCL to a wide range of language models.

****

Patterning: The Dual of Interpretability

George Wang, Daniel Murfet

Mechanistic interpretability aims to understand how neural networks generalize beyond their training data by reverse-engineering their internal structures. We introduce patterning as the dual problem: given a desired form of generalization, determine what training data produces it. Our approach is based on susceptibilities, which measure how posterior expectation values of observables respond to infinitesimal shifts in the data distribution. Inverting this linear response relationship yields the data intervention that steers the model toward a target internal configuration. We demonstrate patterning in a small language model, showing that re-weighting training data along principal susceptibility directions can accelerate or delay the formation of structure, such as the induction circuit. In a synthetic parentheses balancing task where multiple algorithms achieve perfect training accuracy, we show that patterning can select which algorithm the model learns by targeting the local learning coefficient of each solution. These results establish that the same mathematical framework used to read internal structure can be inverted to write it.

Multiview Self-Representation Learning across Heterogeneous Views

Jie Chen, Zhu Wang, Chuanbin Liu, Xi Peng

Features of the same sample generated by different pretrained models often exhibit inherently distinct feature distributions. Learning invariant representations from large-scale unlabeled visual data in a fully unsupervised transfer manner remains a significant challenge. In this paper, we propose a multiview self-representation learning (MSRL) method in which invariant representations are learned by exploiting the self-representation property of features across heterogeneous views. The features are derived from large-scale unlabeled visual data through transfer learning with various pretrained models and are referred to as heterogeneous multiview data. We introduce an information-passing mechanism that relies on self-representation learning to support feature aggregation over the outputs of the linear model. Moreover, an assignment probability distribution consistency scheme is presented to guide multiview self-representation learning by exploiting complementary information across different views. Consequently, representation invariance across different linear models is enforced through this scheme. Additionally, we provide a theoretical analysis of the assignment probability distribution consistency and the incremental views. Extensive experiments demonstrate that the proposed MSRL method consistently outperforms several state-of-the-art approaches.

Geometric Conformal Prediction with Spatial Ranks and Multivariate Quantiles

Anton Conrad, Eric Moulines, julien perez

In multi-target regression and multi-class classification, uncertainty is inherently multivariate: prediction regions must capture joint dependencies across correlated outputs. Conformal prediction provides distribution-free guarantees, yet extending it to vector-valued outputs remains challenging—scalar aggregation discards geometric structure, while optimal transport (OT) approaches are computationally demanding and sensitive to outliers. We introduce two conformal methods based on geometric quantiles and spatial ranks: Geometric Conformalized Quantile Regression (GCQR) constructs prediction regions from learned conditional geometric quantiles, while Geometric Rank Conformal Prediction (GRCP) uses the radial rank of vector-valued conformity scores as the nonconformity measure. We propose multiple estimators offering different tradeoffs between computational cost and adaptivity to feature-dependent heterogeneity, with scalable learning via partially input-convex neural networks. On multi-target regression and multi-class classification benchmarks, GCQR and GRCP attain near-nominal coverage with consistently tighter prediction regions than scalarized and multivariate baselines.

Shared Semantics, Divergent Mechanisms: Unsupervised Feature Discovery by Aligning Semantics and Mechanisms

Hyunjin Cho, Youngji Roh, Jaehyung Kim

As large language models are increasingly deployed in high-stakes settings, there is a growing need for tools that audit not only model outputs but also the int

ernal computations that produce them.
Circuit analysis is a central approach in mechanistic interpretability, but it i s typically target-conditioned, explaining a single prompt paired with a chosen completion.
This target-conditioned setup can obscure heterogeneity across a model's continu ation distribution.
We introduce distribution-level unsupervised feature discovery, which clusters s ampled continuations using both semantic content and sequence-level mechanistic attributions, without manually specifying target outputs.
Our method represents each continuation with a semantic embedding and a prefix-t o-continuation attribution signature, then optimizes a rate-distortion objective that trades off semantic coherence, mechanistic consistency, and cluster granul arity.
Across clustering and steering analyses, the discovered clusters expose continua tion modes that single-view baselines miss and provide interventional evidence t hat cluster signatures correspond to actionable mechanistic factors.
Overall, our approach complements circuit analysis and behavioral evaluation by providing a scalable audit of the mechanisms underlying a model’s continuation d istribution.

ABCD: All Biases Come Disguised
Mateusz Nowak, Xavier Cadet, Peter Chin
Multiple-choice question (MCQ) benchmarks have been a standard evaluation practi ce for measuring LLMs' ability to reason and answer knowledge-based questions. T hrough a synthetic NonsenseQA benchmark, we observe that different LLMs exhibit varying degrees of label-position-few-shot-prompt bias, where the model either u ses the answer position, the label in front of the answer, the distributions of correct answers present in the few-shot prompt, or a combination of all to answe r each MCQ question. We propose a simple bias-reduced evaluation protocol that r eplaces the labels of each question with uniform, unordered labels and prompts t he LLM to use the whole answer presented. With a simple sentence similarity mode l, we demonstrate improved robustness and lower standard deviation between diffe rent permutations of answers with a minimal drop in the LLM's performance, expos ing the LLM's capabilities under reduced evaluation artifacts, without any help from the prompt examples or the option labels. Across multiple benchmarks and mo dels, this protocol substantially improves the robustness to answer permutations , reducing mean accuracy variance $3\times$ with only a minimal decrease in the model's mean performance. Through ablation studies on various embedding models a nd similarity functions, we show that the method is more robust than the standar d ones.

FasterVAR: Plug-and-Play Acceleration for Visual Autoregressive Models
Senmao Li, Kai Wang, Salman Khan, Fahad Shahbaz Khan, jian Yang, Yaxing Wang
Visual Autoregressive (VAR) modeling departs from the next-token prediction para digm of traditional Autoregressive (AR) models through next-scale prediction, en abling high-quality image generation. However, the VAR paradigm suffers from sha rply increased computational complexity and running time at large-scale steps. A lthough existing acceleration methods reduce runtime for large-scale steps, but rely on manual step selection and overlook the varying importance of different s tages in the generation process. To address this challenge,
we present FasterVAR, a systematic study and plug-and-play acceleration framewor k for VAR models. Our analysis shows that early steps are critical for preservin g semantic and structural consistency and should remain intact, while later step s mainly refine details and can be pruned or approximated for acceleration. Buil ding on these insights, FasterVAR introduces a plug-and-play acceleration strate gy that exploits semantic irrelevance and low-rank properties in late-stage comp utations, without requiring additional training.
Our proposed FasterVAR achieves up to 3.4× speedup with almost no performance lo ss, consistently outperforming existing acceleration baselines. These results hi ghlight stage-aware design as a powerful principle for efficient visual autoregr

essive image generation. Code: https://github.com/sen-mao/FasterVAR

A Machine-Learned Comorbidity Index
Suleman Baloch, Kishlay Jha, Alberto Maria Segre, Philip M. Polgreen, Bijaya Adhikari
Traditional comorbidity scores (e.g., Charlson and Elixhauser) are widely used for risk adjustment and patient stratification, but they have two key limitations: (i) they are largely mortality-centric and do not align well with other clinical outcomes, and (ii) their linear, rule-based structure cannot capture nonlinear, outcome-specific risk relationships. We propose a Machine-Learned Comorbidity Index (MLCI) that maps diagnosis codes to a single scalar by maximizing the normalized Hilbert–Schmidt Independence Criterion (nHSIC) between the learned score and multiple clinical outcomes. MLCI captures nonlinear risk–outcome dependence and is supported by a theory that characterizes when a unified, informative admission-level ordering can be achieved across outcomes. Empirical results on multiple benchmark electronic health record (EHR) datasets show that MLCI outperforms strong baselines across multiple evaluation metrics.

Optimal Transport with Symmetry Groups
Jiechao Zhang, Huichun Zhang, Jian Sun, Wei Zeng
We propose a novel algorithm that accelerates optimal transport by exploiting intrinsic symmetries induced by finite group actions. The core of our approach is to recover the orbit decomposition and the associated algebraic structure directly from the cost matrix—without requiring prior knowledge of the group—and to reduce the original transport problem to a substantially smaller problem on the orbit space. This reduction preserves optimality while achieving a significant drop in computational complexity. We develop efficient solvers for two central classes of optimal transport: linear OT and entropy-regularized OT. Experiments on synthetic data, real-world image datasets, and molecular graph data confirm the efficiency and robustness of the method. To our knowledge, this work is the first to systematically incorporate symmetry groups into optimal transport, providing both a theoretical framework and a practical pathway to computational acceleration.

How Can Mamba Learn In Context with Outliers and Generalize Provably?
Hongkang Li, Songtao Lu, Xiaodong Cui, Pin-Yu Chen, Meng Wang
The Mamba model has gained significant attention for its computational advantages over Transformer-based models, while achieving comparable performance across a wide range of language tasks. Like Transformers, Mamba exhibits in-context learning (ICL) capabilities, i.e., making predictions for new tasks based on a prompt containing input-label pairs and a query, without requiring fine-tuning. Despite its empirical success, the theoretical understanding of Mamba remains limited, largely due to the nonlinearity introduced by its gating mechanism. To the best of our knowledge, this paper presents the first theoretical analysis of the training dynamics of a one-layer Mamba model, which consists of a linear attention component followed by a nonlinear gating layer, and its ICL generalization on unseen binary classification tasks, even when the prompt includes additive outliers. Our analysis shows that Mamba leverages the linear attention layer to select informative context examples and uses the nonlinear gating layer to suppress the influence of outliers. By establishing and comparing to the analysis of linear Transformers under the same setting, we show that although Mamba may require more training iterations to converge, it maintains accurate predictions even when the proportion of outliers exceeds the threshold that a linear Transformer can tolerate. These theoretical findings are supported by empirical experiments.
****

Enhancing Conformal Prediction via Class Similarity
Ariel Fargion, Lahav Dabah, Tom Tirer
Conformal Prediction (CP) has emerged as a powerful statistical framework for reliable classification, which generates a prediction set, guaranteed to include the true label with a pre-specified probability. The performance of CP methods is

typically assessed by their average prediction set size. In setups where the cl
asses can be partitioned into semantic groups, e.g., based on shared downstream
actions or more interpretable coarse labels, users can benefit from prediction s
ets that are not only small but also contain a limited number of groups. This pa
per begins by addressing this problem and ultimately offers a widely applicable
tool for boosting any CP method on any dataset. First, given a class partition,
we propose augmenting the CP score function with a term that penalizes predictio
ns with "out-of-group" errors. We theoretically analyze this strategy and prove
its advantages for group-related metrics. Surprisingly, we show mathematically t
hat, for common class partitions, it can also reduce the average set size of *an
y* CP score function. Our analysis reveals the class-similarity factors behind t
his improvement and motivates a variant that can further reduce prediction set s
ize by leveraging the model's embeddings, *without requiring any human semantic
partition*. Finally, we present an extensive empirical study, encompassing promi
nent CP methods, multiple models, and several datasets, which demonstrates that
our class-similarity-based approach consistently enhances CP methods.

CCLRec: Consensus-driven Contrastive Learning for LLM-enhanced Graph Recommendat
ion

Ting Guo, Dongyu Pei, Litiao Qiu, Xiaoying Liao, KE LIANG, Peng Song, Pinle Qin
Recommendation systems seek to accurately model user preferences from a large se
t of candidate items. Graph neural networks (GNNs) have emerged as a dominant ap
proach in this domain due to their ability to capture high-order user–item inter
actions. Recent efforts have aimed to enhance GNN-based representation learning
by incorporating the semantic reasoning capabilities of large language models (L
LMs). However, existing methods often process graph structural information and L
LM-derived semantic knowledge separately, creating a supervisory gap between str
uctural proximity and semantic relevance. To bridge this gap, we propose CCLRec,
a consensus-driven contrastive learning framework for recommendation. CCLRec de
eply integrates structural and semantic information by identifying consistent si
gnals. Specifically, we first use an LLM to extract semantic representations of
items and to sample candidate positive/negative sets in the semantic space. We t
hen introduce a structural–semantic consensus mining strategy that computes the
intersection between a node’s structural neighbors in the graph and its semantic
ally similar items. This allows us to identify high-confidence positive pairs en
dorsed by both collaborative filtering patterns and LLM-based reasoning. By cent
ering contrastive learning on these consensus pairs and applying a weight-aware
reinforcement mechanism during training, CCLRec significantly amplifies the cont
ribution of high-quality consensus features during training. Experiments across
multiple public benchmarks show that CCLRec consistently outperforms state-of-th
e-art methods on key metrics, demonstrating the effectiveness of our consensus-a
ware design.

VividCam: Learning Unconventional Camera Motions from Virtual Synthetic Videos

Qiucheng Wu, Handong Zhao, Zhixin Shu, Jing Shi, Yang Zhang, Shiyu Chang
Although recent video generative models are getting more capable of following ex
ternal camera controls, imposed by either text descriptions or camera trajectori
es, they still struggle to generalize to unconventional camera motions, which is
crucial in creating truly original and artistic videos. The challenge lies in f
inding sufficient training videos with the intended uncommon camera motions. To
this end, we propose VividCam, a training paradigm that enables diffusion models
to learn complex camera motions from synthetic videos, releasing the reliance o
n collecting realistic training videos. VividCam incorporates multiple disentang
lement strategies that isolate camera motion learning from synthetic appearance
artifacts, ensuring more robust motion representation and mitigating domain shif
t.
We show that our design synthesizes a wide range of precisely controlled camera
motions using surprisingly simple synthetic data. Notably, this synthetic data o
ften consists of basic geometries within a low-poly 3D scene and can be efficien
tly rendered by engines like Unity. Our video results can be found in https://wu

qiuche.github.io/VividCamDemoPage/.

UrbanFusion: Stochastic Multimodal Fusion for Contrastive Learning of Robust Spatial Representations
Dominik J. Mühlematter, Lin Che, Ye Hong, Martin Raubal, Nina Wiedemann
Forecasting urban phenomena such as housing prices and public health indicators requires the effective integration of various geospatial data. Current methods primarily utilize task-specific models, while recent generic models for spatial representations often support only limited modalities and lack multimodal fusion capabilities. To overcome these challenges, we present UrbanFusion, a spatial representation model that features Stochastic Multimodal Fusion (SMF). The framework employs modality-specific encoders to process different types of inputs, including street view imagery, remote sensing data, cartographic maps, and points of interest (POIs) data. These multimodal inputs are integrated via a Transformer-based fusion module that learns unified representations. An extensive evaluation across 41 tasks in 56 cities worldwide demonstrates UrbanFusion’s strong generalization and predictive performance compared to state-of-the-art GeoAI models. Specifically, it 1) outperforms prior models on location-encoding, 2) allows multimodal input during inference, and 3) generalizes well to regions unseen during training. UrbanFusion can flexibly utilize any subset of available modalities for a given location during both pretraining and inference, enabling broad applicability across diverse data availability scenarios.
****
CUPID in the Model Zoo: Online Matchmaking for Selecting Your Dream LLM
Son Nguyen, Xinyuan Liu, Ransalu Senanayake
Users increasingly face the challenge of selecting an appropriate LLM for a given task from a rapidly growing pool of LLMs, each with distinct but often opaque latent properties. Compounding this challenge, users may lack the vocabulary or awareness to explicitly articulate the characteristics they value in an LLM's responses or deployment. We propose an interaction-efficient active learning framework in which a dueling bandit algorithm iteratively selects pairs of LLMs, collects user feedback about their responses, and updates its belief about the user's latent preferences. We introduce a novel belief-aware upper confidence bound strategy that balances exploration of the model pool with exploitation of inferred preferences, enabling efficient alignment between user needs and LLM capabilities under user-specified cost and time budgets. Through diverse experiments on LLMs and human studies, we experimentally verify that our model can efficiently match users to LLMs at a lower cost.
****
Where Concept Erasure Should Occur: Concept–Layer Alignment in Text-to-Video Diffusion Models
Yiwei Xie, Ping Liu, Zheng Zhang
Text-to-video diffusion transformers encode semantic information unevenly across model depth, which constrains effective concept erasure.
We identify a representational bottleneck, termed concept–layer topological alignment, under which target concepts exhibit higher separability at certain representational depths.
Outside these depths, concept and non-target signals remain strongly entangled, limiting the effectiveness of depth-specific erasure.
This observation reframes concept erasure as the problem of identifying representational depths where concept–non-target separation naturally emerges.
Motivated by this structural constraint, we introduce CLEAR, a separability-driven optimization framework for concept erasure that explicitly enforces concept–layer alignment.
CLEAR operationalizes this principle by formulating layer selection as an optimization problem over concept–non-target separability, rather than relying on layer-agnostic or heuristic choices.
To enable this, we introduce a separability-aware objective that favors layers exhibiting stronger concept–non-target separation.
Experiments on large-scale text-to-video diffusion models demonstrate that enfor

cing concept--layer alignment leads to more precise concept suppression while pr
eserving overall generative quality.

Interventional Processes For Causal Uncertainty Quantification
Hugh Dance, Peter Orbanz, Arthur Gretton
Reliable uncertainty quantification for causal effects is crucial in
high-stakes applications, but remains challenging when the target is an entire f
unction rather
than a scalar estimand. In this work, we introduce a GP-based approach for uncer
tainty quantification of interventional functions. The central idea is to build
on recent work representing *interventional* functions as an inner-product of *o
bservational* functions in a reproducing kernel Hilbert space (RKHS), by constru
cting appropriate GP priors for such functions and inferring posteriors from obs
ervational data. Our approach yields closed-form posterior
moments and tractable training and inference, while avoiding pathologies of prev
ious GP prior constructions for RKHS functions. We further derive a practical pr
ocedure for posterior coverage calibration.
Across synthetic benchmarks, causal Bayesian optimization tasks, and a
large-scale real dataset, our method improves uncertainty
quantification while remaining competitive in causal effect estimation.
****
Motion Planning in Compressed Representation Spaces
Lukas Lao Beyer, Sertac Karaman
Deep learning methods have vastly expanded the capabilities of motion planning i
n robotics applications, as learning priors from large-scale data has been shown
 to be essential in capturing the highly complex behavior required for solving t
asks such as manipulation or navigation for autonomous vehicles. At the same tim
e, model-based planning algorithms based on search or optimization remain an ess
ential tool due to their flexibility, efficiency, and the ability to incorporate
 domain knowledge via expert-designed algorithms and objective functions. We pro
pose a new generative framework to unify these two paradigms. First, we learn an
 autoencoder with a high compression ratio and a latent space of hierarchically
ordered, discrete-valued tokens. Leveraging both the dimensionality reduction an
d the hierarchical coarse-to-fine structure learned by this autoencoder, we then
 perform motion planning by directly searching in the latent space of tokens. Th
is search can optimize arbitrary objective functions specified at test time, pro
viding a large degree of flexibility while maintaining efficiency and producing
realistic solutions by relying on the generative capabilities of the highly comp
ressed autoencoder. We evaluate our method on nuPlan and the Waymo Open Motion D
ataset, showing how latent space search can be used for a variety of guided beha
vior generation tasks, achieving strong performance for closed-loop motion plann
ing and multi-agent guided scenario synthesis without requiring any task-specifi
c training.
****
RaBiT: Residual Aware Binarization Training for Accurate and Efficient LLMs
Youngcheon You, Banseok Lee, Minseop Choi, Seonyoung Kim, Hyochan Chong, Changdo
ng Kim, Youngmin Kim, Dongkyu Kim
Efficient deployment of large language models (LLMs) requires extreme quantizati
on, forcing a critical trade-off between low-bit efficiency and performance. Res
idual binarization promises hardware-friendly, matmul-free inference by stacking
 binary ($\pm$1) layers, but is plagued by pathological feature co-adaptation. W
e identify a key failure mode, which we term inter-path adaptation: during Quant
ization-Aware Training (QAT), parallel residual binary paths learn redundant fea
tures, degrading the error-compensation structure and crippling the model's expr
essive capacity. While prior work relies on heuristic workarounds (e.g., path fr
eezing) that limit model capacity, we propose RaBiT, a novel quantization framew
ork that resolves co-adaptation by algorithmically enforcing a residual hierarch
y. Its core mechanism sequentially derives each binary path from a single shared
 full-precision weight, ensuring each path corrects its predecessor's error. Thi
s process is stabilized by a robust initialization that prioritizes functional p

reservation over mere weight approximation. RaBiT redefines the 2-bit accuracy-efficiency frontier: it achieves state-of-the-art performance, rivals even hardware-intensive Vector Quantization (VQ) methods, and delivers a 4.49$\times$ inference speed-up over full-precision models on an RTX 4090.
****
Kernel-based Maximum-of-difference Test for Two-sample Comparison
Dan Pu, Tianyi Zhu, Yao Yan, Wei Lan
Two-sample comparison is a fundamental problem in machine learning, with broad applications such as generative modeling. Although the maximum mean discrepancy (MMD) is widely used, MMD-based tests often exhibit poor or even counterintuitive performance under covariance- and location-shift alternatives, partly due to cancellation effects induced by their sum-of-differences construction. To address this issue, we propose a kernel-based maximum-of-difference (MOD) test, which maximizes the squared discrepancy between within-sample and between-sample average distances, thereby improving sensitivity to subtle distributional differences. We further develop a fused MOD procedure to adaptively combine multiple kernels. Extensive experiments demonstrate clear performance gains over existing MMD-based methods.
****
CoCoQuant: Breaking the Bandwidth Wall via Co-Optimized Communication and Computation Quantization
Haojie Duanmu, Jifeng Ding, Size Zheng, Xuegui Zheng, Jiangfei Duan, Xingcheng Zhang, Li-Wen Chang, Xin Liu, Dahua Lin
The rapid scaling of large language models (LLMs) has made distributed inference indispensable, yet end-to-end latency is increasingly dominated by communication, forming a critical bandwidth wall that fundamentally limits the practical gains of existing quantization techniques. Existing approaches typically treat communication and computation in isolation, failing to exploit their coupled nature and introducing limited system-level acceleration and accuracy degradation. To address this, we propose CoCoQuant, a co-designed framework that jointly optimizes communication and computation as a unified end-to-end design space. CoCoQuant introduces a precision-aligned graph-rewriting that enables zero-overhead fusion between low-precision communication and computation. CoCoQuant formulates a hardware-aware mixed-precision allocation problem that integrates roofline-based cost modeling with relative sensitivity calibration, solved via global integer linear programming. Extensive experiments on LLMs of varing scales demonstrate that CoCoQuant achieves Pareto-optimal accuracy-latency trade-offs, delivering up to 2.92 end-to-end speedup with a negligible increase in perplexity (0.22).
****
HPS: Hyperspherical Parameter Sharing for Efficient Multi-Agent Reinforcement Learning
Hu Fu, Pengyi Li, Hao Chen, Xuanyu Xiang, Biao Luo, Yihua Tan
Parameter Sharing (PS) is widely used to improve efficiency in Multi-Agent Reinforcement Learning (MARL), but it can limit behavioral diversity and degrade performance. This limitation stems from gradient conflicts among agents on shared weights, which hinders effective policy learning. To fully characterize this phenomenon, we propose Geometric Gradient Decomposition Analysis that decomposes gradients with respect to weight vector into radial (scale) and tangential (direction) components and uncover a key insight: agents largely agree on directional updates but substantially disagree on scale updates. Consequently, while recent methods split the shared network into agent-specific subnetworks to mitigate conflicts, they also discard shared directional updates, limiting training efficiency. To address this issue, we propose Hyperspherical Parameter Sharing (HPS), which explicitly decouples direction and scale in parameter sharing. Specifically, HPS constrains the shared backbone weights onto a Riemannian manifold(unit hypersphere), enforcing purely directional learning. Building on this, an agent-specific scale generator outputs multiplicative modulation factors to adjust each agent’s scales, thus preserving heterogeneous response magnitudes without disrupting the shared directions. Experiments on SMAC, SMACv2, VMAS and Predator Prey demonstrate that HPS effectively resolves the scale conflict, significantly outperfor

ming state-of-the-art methods.

Revisiting Anisotropy in Language Transformers: The Geometry of Learning Dynamic
s

Raphael Bernas, Fanny Jourdan, Antonin Poché, CELINE HUDELOT

Since their introduction, Transformer architectures have dominated Natural Langu
age Processing (NLP). However, recent research has highlighted an inherent aniso
tropy phenomenon in these models, presenting a significant challenge to their ge
ometric interpretation. Previous theoretical studies on this phenomenon are rare
ly based on the underlying representation geometry. In this paper, we extend the
m by providing such theoretical arguments assessing the problematic nature of th
is phenomenon. Furthermore, to observe geometric internal model dynamics, we app
ly mechanistic interpretability (MI) techniques during the model's training chec
kpoints rather than post-hoc, as it is commonly done in the literature. By analy
zing multiple models and their checkpoints -including EuroBERT, the Pythia suite
, and SmolLM2- we investigate the structure of embedding representations and the
ir correlation with the on manifold entropy of their underlying distribution.
****

Learning U-Statistics with Active Inference

Xiaoning Wang, Yuyang Huo, Liuhua Peng, Changliang Zou

U-statistics play a central role in statistical inference. In many modern appl
ications, however, acquiring the labels required for U-statistics is costly. M
otivated by recent advances in active inference, we develop an active inference
framework for U-statistics that selectively queries informative labels to impr
ove estimation efficiency under a fixed labeling budget, while preserving valid
statistical inference. Our approach is built on the augmented inverse probabilit
y weighting U-statistic, which is proposed to incorporate the sampling rule an
d machine learning predictions. We characterize the optimal sampling rule that m
inimizes its variance and design practical sampling strategies. We further exten
d the framework to U-statistic-based empirical risk minimization. Experiments
on real datasets demonstrate substantial gains in estimation efficiency over bas
eline methods, while maintaining target coverage.

Robustifying Vision-Language Models via Test-Time Prompt Adaptation

Xingyu Zhu, Huanshen Wu, Shuo Wang, Beier Zhu, Jiannan Ge, Jiaheng Zhang, Long C
hen

Pre-trained Vision-Language Models (VLMs) such as CLIP achieve strong zero-shot
generalization, but their performance degrades sharply under adversarial perturb
ations. Existing test-time adaptation methods typically rely on sample-level con
fidence heuristics, overlooking the intrinsic distributional structure of the da
ta. This sample-centric approach limits robustness, as it fails to distinguish c
onfident adversarial mispredictions from true semantic consistency. In this work
, we observe that adversarial distortion is structurally brittle: while holistic
 representations are corrupted, semantic integrity is often preserved in the dis
tribution of augmented views. Motivated by this insight, we propose $\texttt{RIT
A}$, a $\textbf{R}$obust test-t$\textbf{I}$me promp$\textbf{T}$ $\textbf{A}$dapt
ation framework that shifts from sample-level estimates to distribution-level al
ignment. Specifically, $\texttt{RITA}$ employs optimal transport to align the di
stribution of augmented visual features with textual prototypes, mitigating adve
rsarial outliers and rectifying cross-modal semantic misalignment. Furthermore,
we introduce a dynamic cache to progressively accumulate reliable cues from the
test stream for online refinement. Extensive experiments demonstrate that $\text
tt{RITA}$ significantly improves adversarial robustness without compromising cle
an accuracy.
****

Mechanisms of Introspective Awareness

Uzay Macar, Li Yang, Zifan Wang, Peter Wallich, Emmanuel Ameisen, Jack Lindsey

Recent work shows that LLMs can sometimes detect when steering vectors are injec
ted into their residual stream and identify the injected concept, a phenomenon c
ited as evidence of "introspective awareness." But what mechanisms underlie this

capability, and do they reflect genuine introspective circuitry or more shallow heuristics? We investigate these questions in open-source models and establish three main findings. First, introspection is behaviorally robust: detection achieves moderate true positive rates with 0% false positives across diverse prompts. We also find this capability emerges specifically from post-training rather than pretraining. Second, introspection is not reducible to a single linear confound: anomaly detection relies on distributed MLP computation across multiple directions, implemented by interpretable gate and evidence-carrier features. Third, models possess greater introspective capability than is elicited by default: ablating refusal directions improves detection by ~50% and a trained steering vector improves detection by ~75%. Overall, our results suggest that introspective awareness is behaviorally robust, grounded in nontrivial internal anomaly detection, and likely could be substantially improved in future models.

Dr. Kernel: Reinforcement Learning Done Right for Triton Kernel Generations
Wei Liu, Jiawei Xu, Yingru Li, Longtao Zheng, Tianjian Li, Qian Liu, Junxian He
High-quality kernel is critical for scalable AI systems, and enabling LLMs to generate such code would advance AI development. However, training LLMs for this task requires sufficient data, a robust environment, and the process is often vulnerable to _reward hacking_ and _lazy optimization_. In these cases, models may hack training rewards or prioritize trivial correctness over meaningful speedup. In this paper, we systematically study reinforcement learning (RL) for kernel generation. We first design **KernelGYM**, a robust distributed GPU environment that supports reward hacking check, data collection from multi-turn interactions and long-term RL training. Building on KernelGYM, we investigate effective multi-turn RL methods and identify a biased policy gradient issue caused by self-inclusion in GRPO. To solve this, we propose Turn-level Reinforce-Leave-One-Out (**TRLOO**) to provide unbiased advantage estimation for multi-turn RL. To alleviate lazy optimization, we incorporate mismatch correction for training stability and introduce Profiling-based Rewards (**PR**) and Profiling-based Rejection Sampling (**PRS**) to overcome the issue. The trained model, Dr. Kernel-14B, reach performance competitive with Claude-4.5-Sonnet in Kernelbench. Finally, we study sequential test-time scaling for Dr. Kernel-14B, which even **outperforms** GPT-5 and Claude-4.5-Sonnet in the Kernelbench level-2 subset.

Safety Alignment of LMs via Non-cooperative Games
Anselm Paulus, Ilia Kulikov, Brandon Amos, Rémi Munos, Ivan Evtimov, Kamalika Chaudhuri, Arman Zharmagambetov
Ensuring the safety of language models (LMs) while maintaining their usefulness remains a critical challenge in AI alignment. Current approaches rely on sequential adversarial training: generating adversarial prompts and fine-tuning LMs to defend against them. We introduce a different paradigm: framing safety alignment as a non-zero-sum game between an Attacker LM and a Defender LM trained jointly via online reinforcement learning. Each LM continuously adapts to the other's evolving strategies, driving iterative improvement. Our method uses a preference-based reward signal derived from pairwise comparisons instead of point-wise scores, providing more robust supervision and potentially reducing reward hacking. Our RL recipe, AdvGame, shifts the Pareto frontier of safety and utility, yielding a Defender LM that is simultaneously more helpful and more resilient to adversarial attacks. In addition, the resulting Attacker LM converges into a strong, general-purpose red-teaming agent that can be directly deployed to probe arbitrary target models. Code at github.com/facebookresearch/advgame.

Riemannian MeanFlow
Dongyeop Woo, Marta Skreta, Seonghyun Park, Kirill Neklyudov, Sungsoo Ahn
Diffusion and flow models have become the dominant paradigm for generative modeling on Riemannian manifolds, with successful applications in protein backbone generation and DNA sequence design. However, these methods require tens to hundreds of neural network evaluations at inference time, which can become a computational bottleneck in large-scale scientific sampling workflows. We introduce Rieman

nian MeanFlow (RMF), a framework for learning flow maps directly on manifolds, enabling high-quality generations with as few as one forward pass. We derive three equivalent characterizations of the manifold average velocity (Eulerian, Lagrangian, and semigroup identities), and analyze parameterizations and stabilization techniques to improve training on high-dimensional manifolds. In promoter DNA design and protein backbone generation settings, RMF achieves comparable sample quality to prior methods while requiring up to 10$\times$ fewer function evaluations. Finally, we show that few-step flow maps enable efficient reward-guided design through reward look-ahead, where terminal states can be predicted from intermediate steps at minimal additional cost.

Scaling Inference-Time Computation via Opponent Simulation: Enabling Online Strategic Adaptation in Repeated Negotiation

Xiangyu Liu, Di Wang, Zhe Feng, Aranyak Mehta

While large language models (LLMs) have emerged as powerful decision-makers across a wide range of single-agent and stationary environments, fewer efforts have been devoted to settings where LLMs must engage in \emph{repeated} and \emph{strategic} interactions with unknown or dynamic opponents. In such settings, recipes built upon \emph{offline} pre-training or fine-tuning, though robust against worst-case adversaries, do not fully exploit the capability of LLMs to adapt \emph{online} based on interaction feedback. Instead, we explore the more natural perspective of \emph{scaling inference-time computation} as a mechanism for adaptation, embedding the principles of a classical game-theoretical learning dynamic, \emph{smooth Fictitious Play (sFP)}, into LLM inference: (i) for belief formation, we employ an auxiliary opponent model that in-context learns to imitate the \emph{time-averaged} behavior of the opponent; (ii) for best response, we advance best-of-N (BoN) sampling by simulating against the opponent model. Empirical evaluations on two distinct forms of repeated negotiation games demonstrate that our method enables significant performance improvement over online interaction compared to various baselines, offering a scalable and principled approach to strategic decision-making without any parameter updates.

The Information Geometry of Softmax: Probing and Steering

Kiho Park, Todd Nief, Yo Joong Choe, Victor Veitch

This paper concerns the question of how AI systems encode semantic structure into the geometric structure of their representation spaces. The motivating observation is that the natural geometry of these representation spaces should reflect the way models use representations to produce behavior. We focus on the important special case of representations that define softmax distributions. In this case, we argue that the natural geometry is information geometry. Our focus is on the role of information geometry on semantic encoding and the linear representation hypothesis. As an illustrative application, we develop *dual steering*, a method for robustly steering representations to exhibit a particular concept using linear probes. We prove that dual steering optimally modifies the target concept while minimizing changes to off-target concepts. Empirically, we find that dual steering enhances the controllability and stability of concept manipulation.

Hyperbolic RQ-VAE enhanced Generative Recommendation with Differential-Length Codebook Strategy

Aoran Zhang, Yu-Bin Yang, Yonghong Yu

Recently, the integration of large language models (LLMs) with generative recommendation (GR) has demonstrated promising potential. However, most existing GR methods adopt residual quantization to implicitly model hierarchical relationships across codebook layers in Euclidean space, which distorts the intrinsic tree-like hierarchy and leads to low codebook utilization. To address these issues, we propose a Hyperbolic RQ-VAE enhanced Generative Recommendation, namely HG-Rec. Specifically, HG-Rec enhances the residual quantization mechanism by embedding the latent discrete representations into hyperbolic space to explicitly model hierarchical relationships across codebook layers. Motivated by the exponential volume growth of hyperbolic space, we further design a differential-length codebook

strategy, i.e. the codebook size follows a pyramidal structure, which aligns wit
h the tree-like structure and effectively compresses the codebook size. Hence, b
enefiting from the alignment of hyperbolic geometry and codebook hierarchy, HG-R
ec achieves lower collision rates, more uniform codebook usage, and less trainin
g time compared to existing methods. Extensive experiments across multiple bench
mark datasets demonstrate that HG-Rec consistently achieves state-of-the-art per
formance. The code is available in the https://github.com/zar123123/HG-Rec.

Prism-MoE: Efficient Dense-to-MoE Conversion for Visual Autoregressive Generatio
n

Ying Li, Zefang Wang, Zhaode Wang, Zhiwen Chen, chengfei lv, Huan Wang

Scaling up visual autoregressive models improves generation quality but incurs s
ubstantial inference costs. Mixture-of-Experts (MoE) architectures mitigate this
 issue through sparse activation and have proven effective in large language mod
els. However, training MoE models from scratch remains prohibitively expensive,
and dense-to-MoE conversion for visual autoregressive models is still underexplo
red. To enable *low-cost and high-quality dense-to-MoE conversion*, we propose *
*Prism-MoE**, an efficient framework for transforming pretrained dense visual au
toregressive models into sparse MoE models. Prism-MoE consists of two key compon
ents. First, we introduce trajectory-consistent Initialization, which formulate
s expert initialization as a principled decomposition problem and preserves the
generation trajectory of pretrained models. Second, we propose a confidence-adap
tive sparse fine-tuning framework that aligns expert specialization with the inf
ormation density of visual tokens via confidence-aware routing supervision. Expe
riments show that Prism-MoE achieves dense-to-MoE conversion with less than **10
\%** of the standard training budget, while maintaining generation quality compa
rable to dense baselines with only **37.5\%** active parameters.

UMEM: Unified Memory Extraction and Management Framework for Generalizable Memor
y

Yongshi Ye, Hui Jiang, Feihu Jiang, Tian Lan, Yichao Du, Biao Fu, Xiaodong Shi,
Qianghuai Jia, Longyue Wang, Weihua Luo

Self-evolving memory serves as the trainable parameters for Large Language Model
s (LLMs)-based agents, where extraction (distilling insights from experience) an
d management (updating the memory bank) must be tightly coordinated.
Existing methods predominantly optimize memory management while treating memory
extraction as a static process, resulting in poor generalization, where agents a
ccumulate instance-specific noise rather than robust memories.
To address this, we propose Unified Memory Extraction and Management (UMEM), a s
elf-evolving agent framework that jointly optimizes a LLM to simultaneously extr
act and manage memories.
To mitigate overfitting to specific instances, we introduce Semantic Neighborhoo
d Modeling and optimize the model with a neighborhood-level marginal utility rew
ard via GRPO.
This approach ensures memory generalizability by evaluating memory utility acros
s clusters of semantically related queries.
Extensive experiments across five benchmarks demonstrate that UMEM significantly
 outperforms highly competitive baselines, achieving up to 11.49 points improvem
ent in multi-turn interactive tasks. Furthermore, UMEM maintains a stable improv
ement trend during continuous evolution.

DT^2: Decision-Targeted Digital Twins

Harry Amad, Mihaela van der Schaar

A digital twin (DT) is a virtual model of a real-world system that can assist de
cision-making by simulating scenarios induced by different policies. However, ty
pical machine learning-based DTs do not optimise for this use case. We prove tha
t, when model capacity is limited, training DTs to minimise one-step transition
errors can produce suboptimal models for ranking sets of policies according to a
 reward function. We further show that this holds empirically, even with express
ive model classes. To address this, we introduce DT^2, a decision-targeted DT

training paradigm. Firstly, DT^2 uses fitted Q-evaluation to estimate values of candidate policies from offline data. A DT is then trained to generate rollouts that preserve pairwise policy rankings derived from these proxy ground-truth values with an architecture-agnostic loss function. We empirically demonstrate the efficacy of our method across a range of settings and architectures. DT^2 consistently improves policy ranking and reduces decision regret during policy selection relative to conventional DT training, both for policies used during training and for unseen policies, while maintaining a good level of raw simulation fidelity.

Universal Multiclass Transductive Online Learning
Steve Hanneke, Hongao Wang
We consider the problem of universal transductive online classification with a possibly unbounded label space. This setting considers online learning, with the sequence of instances (without labels) known to the learner in advance. We say a concept class $\mathcal{H}$ is learnable if there is a learning algorithm $\mathcal{A}$, such that for every realizable sequence, the number of mistakes made by $\mathcal{A}$ grows at most sublinearly with the number of predictions. We characterize the learnability of this setting and show that there are only two possible optimal rates for the learnable classes: either bounded or increasing logarithmically. We introduce a new combinatorial structure, called "Level-Constrained-Littlestone-Littlestone (LCLL) tree", which, along with the indifference property, characterizes the learnability. We also extend the learnability result to the agnostic case and the case where only the stochastic process that generates the instance sequence is known.

When Agents Go Rogue: Activation-Based Detection of Malicious Behaviors in Multi-Agent Systems
Haowen Xu, Xue Tan, Lei Ma, Zhihao Zhang, Chao Wang, Qingze Wang, Ping Chen, Jun Dai, Xiaoyan Sun
While enabling effective collaboration on complex tasks, LLM-based Multi-Agent Systems (MAS) face critical security challenges due to vulnerabilities at the agent and interaction levels. Most existing MAS security defenses are built upon two core assumptions: semantically-explicit malicious attacks and explicit graph-based modeling of the MAS topology and agent-level interactions. In practice, real-world attacks are becoming more semantically stealthy, while MAS execution is typically asynchronous without the temporal alignment assumed by graph-based propagation models. To address these limitations, we propose AcMAS, an activation-based framework for malicious-behavior detection in MAS. By analyzing internal reasoning states in the activation space of local agents, AcMAS detects even stealthy attacks in a synchronization-robust fashion, without relying on explicit interaction graphs. Moreover, our activation analysis provides critical signals to guide AcMAS in restoring the functionality of compromised agents, rather than the disruptive agent isolation commonly used by the state-of-the-art methods. Comprehensive evaluation demonstrates that AcMAS significantly outperforms graph-based baselines against stealthy attacks, by +0.22 F1 in synchronous settings (0.94 vs. 0.72) and by +0.55 F1 in asynchronous settings (0.93 vs. 0.38), with generalization across diverse open-source LLM backbones, attack intensity, and MAS scale.

Policy Search via Bayesian Optimization with Temporal Difference Gaussian Processes
Armin Lederer, Anuj Srivastava, Marco Bagatella, Andreas Krause
Bayesian optimization (BO) is a method commonly used for policy search in problems with low-dimensional policy parameterizations. While it is generally considered data-efficient, existing BO approaches are agnostic to the sequential structure of the optimization objective induced by policy roll-outs. Thereby, valuable information is discarded that could improve the convergence of BO. We address this inefficiency by developing and rigorously analyzing a novel approach for BO that relies on a temporal difference learning formulation for discounted infinit

e-horizon value functions based on Gaussian process (GP) regression. We derive l
earning error bounds for the proposed temporal difference GPs, such that we can
exploit upper confidence bounds to analyze the cumulative regret of our BO appro
ach. This analysis is further refined by bounding the maximal information gain f
or our temporal difference GP model. In a comparison with relevant baseline meth
ods, we demonstrate the practical advantages of our method.

Variational Adapter for Cross-modal Similarity Representation
WenZhang Wei, Zhipeng Gui, Dehua Peng, Tiandi Ye, Huayi Wu
The core of vision-language models lies in measuring cross-modal similarity with
in a unified representation space. However, most image-text matching or multi-cl
ass image classification datasets lack fine-grained cross-modal matching annotat
ions, forcing the continuous similarity space into binary classification boundar
ies. This compression induces false negative samples and significantly impairs t
he generalization performance of cross-modal tasks. While prior research has att
empted to mitigate this by modeling intra-modal ambiguity, it often overlooks in
herent annotation flaws, leading to suboptimal uncertainty allocation. To addres
s these challenges, we propose a Variational Adapter for Cross-modal Similarity
Representation (VACSR). This approach reformulates image-text matching with fine
-grained semantic scarcity as a variational inference problem. It constructs a l
atent space for cross-modal similarity and uses regularization techniques to mit
igate overfitting to binary annotations. Experiments on image-text retrieval, do
main generalization, and base-to-novel generalization demonstrate the proposed m
ethod’s effectiveness and robust generalization ability.

CVE-Factory: Scaling Expert-Level Agentic Tasks for Code Security Vulnerability
Xianzhen Luo, Jingyuan Zhang, Shiqi Zhou, JinYang Huang, Chuan Xiao, Qingfu Zhu,
 Zhiyuan Ma, YUE XING, Yang Yue, Wencong Zeng, Wanxiang Che
Evaluating and improving the security capabilities of code agents requires high-
quality, executable vulnerability tasks. However, existing works rely on costly,
 unscalable manual reproduction and suffer from outdated data distributions. To
address these, we present CVE-Factory, the first multi-agent framework to achiev
e expert-level quality in automatically transforming sparse CVE metadata into fu
lly executable agentic tasks. Cross-validation against human expert reproduction
s shows that CVE-Factory achieves 95\% solution correctness and 96\% environment
 fidelity, confirming its expert-level quality. It is also evaluated on the late
st realistic vulnerabilities and achieves a 66.2\% verified success. This automa
tion enables two downstream contributions. First, we construct LiveCVEBench, a c
ontinuously updated benchmark of 190 tasks spanning 14 languages and 153 reposit
ories that captures emerging threats including AI-tooling vulnerabilities. Secon
d, we synthesize over 1,000 executable training environments, the first large-sc
ale scaling of agentic tasks in code security.
Fine-tuned Qwen3-32B improves from 5.3\% to 35.8\% on LiveCVEBench, surpassing C
laude 4.5 Sonnet, with gains generalizing to Terminal Bench (12.5\% to 31.3\%).
We open-source all code, data, and models.
****

Online Rubrics Elicitation from Pairwise Comparisons
MohammadHossein Rezaei, Robert Vacareanu, Zihao Wang, Clinton Wang, Bing Liu, Yu
nzhong He, Afra Feyza Akyürek
Rubrics provide a flexible way to train LLMs on open-ended long-form answers whe
re verifiable rewards are not applicable and human preferences provide coarse si
gnals. Prior work shows that reinforcement learning with rubric-based rewards le
ads to consistent gains in LLM post-training. Most existing approaches rely on r
ubrics that remain static over the course of training. Such static rubrics, howe
ver, are vulnerable to reward-hacking type behaviors and fail to capture emergen
t desiderata that arise during training. We introduce Online Rubrics Elicitation
 (OnlineRubrics), a method that dynamically curates evaluation criteria in an on
line manner through pairwise comparisons of responses from current and reference
 policies. This online process enables continuous identification and mitigation
of errors as training proceeds. Empirically, this approach yields consistent imp

rovements of up to 8% over training exclusively with static rubrics across AlpacaEval, GPQA, ArenaHard as well as the validation sets of expert questions and rubrics. We qualitatively analyze the elicited criteria and identify prominent themes such as transparency, practicality, organization, and reasoning.

EigenCache: Rethinking Diffusion Acceleration as Covariance-Optimal Forecasting and Submodular Information Allocation

Chenyang Xu, Dezhen Wang, Lin Chen, Kepeng Lin, Hao Wang

Accelerating diffusion models via feature caching has progressed from static feature reuse to polynomial extrapolation, yet current cache-then-forecast strategies still rely on hand-crafted approximation families (e.g., Taylor or Hermite bases) that can misalign with the non-stationary, layer-specific dynamics of generative features. This paper introduces EigenCache, a training-free framework that re-frames diffusion acceleration as covariance-adaptive feature forecasting and uncertainty-aware temporal design. EigenCache models cached feature trajectories as time-indexed stochastic processes and estimates layer-wise temporal kernels from a small calibration set. Under the resulting scalar temporal-kernel approximation, the Gaussian-process posterior mean, i.e., Kriging, is risk-optimal within the scalar-weighted linear predictor class; under joint Gaussianity, it further coincides with the MMSE estimator. This formulation generalizes fixed-basis forecasting from a covariance-adaptive perspective while providing a closed-form posterior-variance proxy for prediction uncertainty. Leveraging this proxy, EigenCache selects computation anchors by maximizing a log-determinant information-gain objective over denoising timesteps, a monotone submodular objective with a near-optimal greedy solution. Across image, video, transformer, U-Net, and LoRA-adapted diffusion models, EigenCache achieves a strong speed--fidelity Pareto frontier and provides a principled mechanism for robust compute allocation.

Risk-Averse and Optimistic Advertiser Incentive Compatibility in Auto-bidding

Christopher Liaw, Wennan Zhu

The rise of auto-bidding in online advertising has created new challenges for ensuring advertiser incentive compatibility, particularly when advertisers delegate bidding to agents with high-level constraints. One challenge is the multiplicity of equilibria with reported constraints. Alimohammadi et al. (2023) proposed a notion of Auto-bidding Incentive Compatibility (AIC) which serves to highlight that standard auctions may not incentivize truthful reporting of these constraints. However, their definition of AIC is very stringent as it requires that the worst-case outcome of an advertiser's truthful report is at least as good as the best-case outcome of any of the advertiser's possible deviations. In this paper, we introduce two refined and relaxed concepts: Risk-Averse Auto-bidding Incentive Compatibility (RAIC) and Optimistic Auto-bidding Incentive Compatibility (OAIC). RAIC (OAIC) stipulates that truthful reporting is preferred if its least (most) favorable equilibrium outcome is no worse than the least (most) favorable equilibrium outcome from any misreport. We demonstrate that SPA satisfies both RAIC and OAIC. These findings clarify SPA's incentive properties under auto-bidding, specifically regarding advertiser perspectives on equilibrium selection.

Benchmarking at the Edge of Comprehension

Samuele Marro, Jialin Yu, Emanuele La Malfa, Oishi Deb, Jiawei Li, Yibo Yang, Ebey Abraham, Sunando Sengupta, Eric Sommerlade, Michael J. Wooldridge, Philip Torr

As frontier Large Language Models (LLMs) increasingly saturate new benchmarks shortly after they are published, benchmarking itself is at a juncture: if frontier models keep improving, it will become increasingly hard for humans to generate discriminative tasks, provide accurate ground-truth answers, or evaluate complex solutions.

If benchmarking becomes infeasible, our ability to measure any progress in AI is at stake. We refer to this scenario as the *post-comprehension regime*.

In this work, we propose Critique-Resilient Benchmarking, an adversarial framework designed to compare models even when full human understanding is infeasible.

Our technique relies on the notion of *critique-resilient correctness*: an answe
r is deemed correct if no adversary has convincingly proved otherwise.
Unlike standard benchmarking, humans serve as bounded verifiers and focus on loc
alized claims, which preserves evaluation integrity beyond full comprehension of
 the task.
Using an itemized bipartite Bradley-Terry model, we jointly rank LLMs by their a
bility to solve challenging tasks and to generate difficult yet solvable questio
ns.
We showcase the effectiveness of our method in the mathematical domain across ei
ght frontier LLMs, showing that the resulting scores are stable and correlate wi
th external capability measures.
Our framework reformulates benchmarking as an adversarial generation-evaluation
game in which humans serve as final adjudicators.
****

Active Curriculum Refinement for Reinforcement Learning
Zhenya Liu, Yuxin Chen
In many RL domains, environments are linked by prerequisite relations—e.g., diff
iculty-increasing edits or parameter increments—which induce a directed acyclic
curriculum graph (DAG). In practice, this structure is often exploited only impl
icitly, yet it can yield clear gains in training. We introduce PATH, a curriculu
m learning framework that performs active learning on the curriculum graph. PATH
 first expands coverage by sampling diverse curriculum paths, then reallocates t
raining toward regions that remain unmastered. Experiments show that PATH levera
ges the graph structure to achieve strong robustness and generalization across d
iverse environments.

PolicyGuard: Towards Test-time and Step-level Adversary Defense for Reinforcemen
t Learning Agent
Junfeng Guo, Heng Huang
While real-world applications of reinforcement learning (RL) are becoming increa
singly popular, the security of RL systems deserve more attention and exploratio
n. In particular, recent work has revealed that RL agents are vulnerable to back
door attacks, where a victim agent behaves normally under standard conditions bu
t executes malicious actions when a specific trigger is activated. Existing back
door defenses for RL either require access to the agent’s internal parameters, o
perate only at the model or trajectory level, or are limited to specific attack
types. To ensure the security of RL agents, we propose PolicyGuard, a test-time
step-level backdoor defense which leverages Gaussian Process (GP) posterior vari
ance and adapts pseudo trajectories to enable uncertainty computation for indivi
dual time step. Besides, we also provide theoretical foundations to explain the
efficacy of GP posterior variance. Extensive experiments across seven RL games d
emonstrate that PolicyGuard achieves state-of-the-art detection performance in m
ost cases, with average AUROC of 0.856 for perturbation-based attacks and 0.859
for adversary-agent attacks.
****

Efficient numeracy in language models through single-token number embeddings
Linus Kreitner, Paul Hager, Jonathan Mengedoht, Georgios Kaissis, Daniel Ruecker
t, Martin J. Menten
To drive progress in science and engineering, large language models (LLMs) must
be able to process large amounts of numerical data and solve long calculations e
fficiently. This is currently only possible through the use of external tools or
 extensive reasoning chains, either weakening the numerical representations of L
LMs or limiting the length of problems they can solve. We show that frontier LLM
s require excessive amounts of reasoning tokens to solve even basic calculations
, which is exacerbated by their tokenization strategies that split single number
s into multiple tokens. This motivates the need for efficient and effective sing
le-token number encodings. We introduce a set of desiderata for such encodings a
nd show that existing approaches fail to fulfill them. To address these shortcom
ings, we propose BitTokens, a novel encoding strategy that represents any number
 as a single token using its IEEE 754 binary floating-point representation. Thro

ugh extensive experiments we show that our BitTokens allow even small language m
odels to learn algorithms that solve basic arithmetic operations nearly perfectl
y. This newly gained efficiency could expand the length and complexity of proble
ms language models can solve.

Automatic Unsupervised Ensemble Outlier Model Selection

Hong-Phuc Phan, Tuan-Anh Vu, Tung Kieu, Son Ha Xuan, Bin Yang, Christian S. Jens
en

Unsupervised outlier detection is attractive because it eliminates the need for
labeled data. Moreover, forming multi-model ensembles can improve detection robu
stness. However, composing an ensemble without labeled data is challenging. Naiv
ely composed ensembles can suffer from ensemble saturation, where redundant or u
nreliable detection models degrade performance and incur unnecessary computation
. We propose MetaEns, an automatic unsupervised framework for selecting ensemble
s of outlier detection models. Using labeled meta-datasets, MetaEns learns a mod
el that predicts marginal ensemble gains, estimating the expected improvement fr
om adding a candidate model to a partially constructed ensemble. At test time, t
his learned signal is combined with a submodular-inspired proxy objective that e
nforces diminishing returns through diversity-aware discounting and family-level
 risk regularization, thereby enabling reedy sequential selection with adaptive
early stopping. As a result, MetaEns constructs compact, high-quality ensembles
without access to ground-truth labels. Experiments on 39 real-world datasets sho
w that MetaEns consistently outperforms state-of-the-art unsupervised selectors
and ensemble baselines, achieving higher average precision while using fewer mod
els.

CURE: Context-driven Diffusion with Progressive Expansion for Single Domain Gene
ralization in Time Series Classification

Yuhang Pei, Fanchun Meng, Wenrui Wu, Tao Ren, Yifan Wang, Wei Ju, Chao Zheng, Xi
ao Luo

This paper studies the problem of single domain generalization in time series cl
assification, which aims to learn a generalized time series classification model
 using a single source domain. This problem is highly challenging due to unrelia
ble supervision from domain scarcity. Although current approaches employ generat
ive models for data augmentation, these synthesized samples often suffer from lo
w diversity and intrinsic noise, leading to weak generalization ability. Towards
 this end, we propose a novel approach named Context-driven Diffusion with Prog
ressive Expansion (CURE) for single domain generalization in time series classif
ication. The core of our CURE is to generate semantic-aware and semantic-free co
ntexts that jointly guide a conditional diffusion model for informative data exp
ansion. In particular, our CURE first conducts representation disentanglement to
 extract semantic-aware and semantic-free representations from source data. To e
nhance generalizability through data synthesis, we not only retrieve reference t
ime series trajectories with similar semantics for semantic-aware contexts, but
also utilize adversarial strategies to learn semantic-free contexts. These conte
xts are integrated as joint conditions for a diffusion model, enabling diverse a
nd reliable virtual data. To enhance expansion adaptability and stable optimizat
ion, we progressively update our semantic-free contexts via a memory bank and me
asure boundary properties for dynamic data filtering. Comprehensive experiments
on benchmark datasets validate the effectiveness of CURE.
****

Dirichlet-Prior Shaping: Guiding Expert Specialization in Upcycled MoEs

Leyla Mirvakhabova, Babak Ehteshami Bejnordi, Gaurav Kumar, Hanxue Liang, Wanru
Zhao, Paul N. Whatmough

Upcycling pre-trained dense models into sparse Mixture-of-Experts (MoEs) efficie
ntly increases model capacity but often suffers from poor expert specialization
due to naive weight replication. We introduce Dirichlet-Prior Shaping Loss (DPSL
), a novel router regularization technique that directly shapes routing probabil
ity distributions by matching expert assignments to a target Dirichlet prior res
ulting in enhanced expert specialization. DPSL enables encoding of inductive bia

ses such as encouraging experts to focus on specific modalities or tasks, withou t requiring manual intervention. DPSL is a general tool applicable to any module that outputs categorical probability distributions, extending its utility beyon d MoE training. Experiments on upcycled MoE vision-language models show that DPS L consistently outperforms upcycling strategies and regularization techniques ac ross standard vision-language benchmarks, addressing the critical issue of poor specialization and fostering higher-performing models.

World Models in Pieces: Structural Certification of General Agents
Yikai Lu, Yifei Wu, Xinyu Lu, Tongxin Li
In the big-world regime, agents cannot be universally capable and their ability is inevitably specialized across a world model in pieces. Consequently, standard uniform guarantees fail to distinguish between the understanding of critical bo ttlenecks and irrelevant failures. We first formalize this limitation by proving that *general agents are not universal*, rendering standard worst-case analysis uninformative. To overcome this, we introduce **structural certification**, a t ransition-local framework that maps bounded goal-conditioned performance to entr y-wise guarantees on the agent's internal world model. Our main contribution is constructive. We provide algorithms that filter specific transitions using deep compositional goals and prove that a general agent on these goals has a structur al world model with a $\mathcal{O}(1/n)+\mathcal{O}(\delta)$ error bound. Conve rsely, this bound is tight in the small-δ regime, whose existence is expl icitly guaranteed by our certification. These results enable the certifiable dep loyment of general agents by localizing the specific transitions where long-hori zon planning is reliable.

CFPO: Counterfactual Policy Optimization for Multimodal Reasoning
ZhangYuan Yu, Wanran Sun, Guangjing Yang, Xiaohu Wu, Qicheng Lao
Large Vision-Language Models (LVLMs) have demonstrated remarkable capabilities i n multimodal reasoning. However, prevailing reinforcement learning (RL) paradigm s lack explicit counterfactual enhancement and causal learning mechanisms. This fundamental deficiency results in severe grounding failures, manifesting as a te ndency to ignore visual evidence in favor of language priors or exhibiting hallu cination drift during long chain-of-thought reasoning. To address this root caus e, we propose CounterFactual Policy Optimization (CFPO), a novel framework that enforces causal consistency between visual perception and textual reasoning. CFP O introduces a cross-modal counterfactual enhancement mechanism, which regulariz es the policy by maximizing the discrepancy between the model’s predictions and those from a counterfactual state where critical visual cues are suppressed. Thi s approach seamlessly integrates with standard algorithms like GRPO and DAPO wit hout requiring external reward models or additional supervision. Extensive exper iments demonstrate that CFPO significantly improves reasoning fidelity, achievin g consistent gains of 3.17%-6.25% over standard RL baselines and 1.32%-2.13% ove r the state-of-the-art perception-aware method (PAPO). Code is available at http s://github.com/Raven-July/CFPO.

CONGA:Confidence-and-Gradient-Aware Learning Rate Schedule for Test Time Adaptat ion
Lv Shaoran, Xinyao Li, Jingjing Li
Test-time adaptation (TTA) adapts pretrained models to test data on-the-fly. Cur rent TTA methods have focused on what to adapt: lightweight domain-aware compone nts (prompts, normalization statistics) updated with consistency-aware self-supe rvised losses. This work investigates the more fundamental yet underexplored opt imization process, providing insights and guidelines on how to appropriately upd ate models for TTA. By analyzing the optimization error during TTA, we identify a pivotal stability-plasticity trade-off: the model should adapt to novel distri butions while retaining learned knowledge, which motivates our design of a CONfi dence-and-Gradient-Aware scheduler (CONGA) to constrain model learning rate (LR) within an adaptive exploration interval. For each iteration, the lower bound e ncourages model exploration on informative confident samples, while the upper bo

und prevents aggressive overfitting to noisy optimization gradients. Based on ou r theoretical findings, an adaptation-progress-conditioned cosine decay function decides the specific LR within the interval. As an LR scheduler, CONGA is natu rally applicable on existing TTA methods as a plug-in module, introducing little computation overheads. Extensive experiments and analysis demonstrate the super iority and validness of CONGA.

ITSPACE: Monotone Gaussian Optimal Transport Updates
Woojoo Na, Jennifer Dy
Covariance matrices serve as compact descriptors of feature distributions in man y machine-learning pipelines, including domain adaptation and Gaussian embedding s. Under a centered Gaussian approximation, the *unregularized* Wasserstein-2 *o ptimal transport* (OT) discrepancy admits a closed form on covariances given by the *Bures--Wasserstein* (BW) objective on the *symmetric positive definite* (SP D) cone. We propose **ITSPACE** (Iterative Transport for Stable Proximal Alignme nt of Covariance Embeddings), a proximal majorization-minimization method that d irectly optimizes this exact BW objective through closed-form updates in a squar e-root factorization. In exact arithmetic, each iteration satisfies a sufficient -decrease inequality for the BW objective; under inexact polar computations, we provide an explicit certificate-gap bound controlling deviations from exact desc ent. The resulting iterations preserve PSD structure by construction and natural ly support rank-restricted factors, making **ITSPACE** well-suited as a lightwei ght inner-loop primitive in settings where adaptation must be performed from unl abeled target batches under strict step and compute budgets. Across real-world c ovariance-alignment benchmarks, **ITSPACE** reaches low-BW-gap solutions substan tially faster than BW-gradient descent, methods based on other covariance geomet ries, and entropically regularized sample-OT baselines.

Time series saliency maps: Explaining models across multiple domains
Christodoulos Kechris, Jonathan Dan, David Atienza
Traditional saliency map methods, popularized in computer vision, highlight indi vidual input points that contribute most to a model's output. However, in the co ntext of time series, they offer limited insights because semantically meaningfu l features are often found in other domains. Thus, we introduce in this paper Cr oss-domain Integrated Gradients, a generalization of Integrated Gradients that e nables feature attributions in any domain formulated as an invertible, different iable transformation of the time domain. Our derivation extends Integrated Gradi ents into complex-valued domains, enabling frequency-based attributions, while p reserving path independence and completeness. We validate our method via control led mechanistic experiments, quantitative faithfulness and perturbation-stabilit y tests, and real-world case studies. Across wearable heart-rate extraction, EEG -based seizure detection, and zero-shot forecasting, our proposed Cross-domain I ntegrated Gradients approach identifies whether predictions rely on heart-rate f requencies or interference, epileptic sources or artifacts, and trend or seasona l components, revealing model behaviour that time-domain saliency does not captu re. We release an open-source library with TensorFlow, native PyTorch, and Captu m support for plug-and-play cross-domain explainability of time-series models.

The Value of Variance: Mitigating Debate Collapse in Multi-Agent Systems via Unc ertainty-Driven Policy Optimization
Luoxi Tang, Yuqiao Meng, Joseph Costa, Yingxue Zhang, Muchao Ye, Zhaohan Xi
Multi-agent debate (MAD) systems improve LLM reasoning through iterative deliber ation, but remain vulnerable to debate collapse, a failure type where final agen t decisions are compromised on erroneous reasoning. Existing methods lack princi pled mechanisms to detect or prevent such failures. To address this gap, we firs t propose a hierarchical metric that quantifies behavioral uncertainty at three levels: intra-agent (individual reasoning uncertainty), inter-agent (interactive uncertainty), and system-level (output uncertainty). Empirical analysis across several benchmarks reveals that our proposed uncertainty quantification reliably indicates system failures, which demonstrates the validity of using them as dia

gnostic metrics to indicate the system failure. Subsequently, we propose a mitig ation strategy by formulating an uncertainty-driven policy optimization to penal ize self-contradiction, peer conflict, and low-confidence outputs in a dynamic d ebating environment. Experiments demonstrate that our proposed uncertainty-drive n mitigation reliably calibrates the multi-agent system by consistently improvin g decision accuracy while reducing system disagreement.

Fine-grained Analysis of Brain-LLM Alignment through Input Attribution
Michela Proietti, Roberto Capobianco, Mariya Toneva
Understanding the alignment between large language models (LLMs) and human brain activity can reveal computational principles underlying language processing. Th is work describes a pipeline to apply attribution methods to the brain-LLM align ment setting to identify the specific words most important for this alignment. A s a case study, we leverage it to study a contentious research question about br ain-LLM alignment: the relationship between brain alignment (BA) and next-word p rediction (NWP). Across two naturalistic fMRI datasets, we find that BA and NWP rely on largely distinct word subsets: NWP exhibits recency and primacy biases w ith a focus on syntax, while BA prioritizes semantic and discourse-level informa tion with a more targeted recency effect. This work advances our understanding o f how LLMs relate to human language processing and highlights differences in fea ture reliance between BA and NWP. Beyond this study, our attribution method can be broadly applied to explore the cognitive relevance of model predictions in di verse language processing tasks.

AgentLAB: Benchmarking LLM Agents against Long-Horizon Attacks
Tanqiu Jiang, Yuhui Wang, Jiacheng Liang, Ting Wang
LLM agents are increasingly deployed in long-horizon, complex environments to so lve challenging problems, but this expansion exposes them to long-horizon attack s that exploit multi-turn user–agent–environment interactions to achieve objecti ves infeasible in single-turn settings. To measure agent vulnerabilities to such risks, we present AgentLAB, the first benchmark dedicated to evaluating LLM age nt susceptibility to adaptive, long-horizon attacks. Currently, AgentLAB support s five novel attack types including intent hijacking, tool chaining, task inject ion, objective drifting, and memory poisoning, spanning 28 realistic agentic env ironments, and 644 security test cases. Leveraging AgentLAB, we evaluate represe ntative LLM agents and find that they remain highly susceptible to long-horizon attacks; moreover, defenses designed for single-turn interactions fail to reliab ly mitigate long-horizon threats. We anticipate that AgentLAB will serve as a va luable benchmark for tracking progress on securing LLM agents in practical setti ngs. The code for AgentLAB is available at:
https://tanqiujiang.github.io/AgentLAB_main.

From Interactions to Principles: Experience-Driven Self-Distillation for Evolvin g LLM Agents
Rong Wu, Xiaoman Wang, Jianbiao Mei, Pinlong Cai, Daocheng Fu, Cheng Yang, Liche ng Wen, Xuemeng Yang, Yufan Shen, Yuxin Wang, Botian Shi
LLM agents have achieved strong performance in tool-augmented reasoning, but mos t remain largely stateless: after each episode, the agent discards interaction t races and does not accumulate reusable strategies. Prior work either stores raw trajectories for case-based reuse or relies on external teacher models to write reflections, which limits generalization or leaves the agent’s policy unchanged. We introduce EvolveR, an experience-driven framework that allows an agent to im prove using its own interaction history. EvolveR maintains an experience base of distilled strategic principles derived from past trajectories. In an offline ph ase, the agent self-distills successful and failed trajectories into concise pri nciples, applies semantic deduplication, and assigns each principle an empirical utility score for maintenance and pruning. In an online phase, the agent retrie ves top-ranked principles to guide reasoning and tool usage, generating new traj ectories. We then perform policy evolution with reinforcement learning on these experience-conditioned trajectories, reinforcing behaviors that effectively retr

ieve and apply useful principles. We demonstrate the effectiveness of EvolveR on complex multi-hop question-answering benchmarks, where it achieves superior performance over strong agentic baselines. Our work presents a comprehensive blueprint for agents that learn not only from external data but also from the consequences of their own actions, paving the way for more autonomous and continuously improving systems.

RiboSphere: Learning Unified and Efficient Representations of RNA Structures
Zhou Zhang, Hanqun Cao, Cheng Tan, Fang Wu, Pheng-Ann Heng, Tianfan Fu
Accurate RNA structure modeling remains difficult because RNA backbones are highly flexible, non-canonical interactions are prevalent, and experimentally determined 3D structures are comparatively scarce. We introduce RiboSphere, a framework that learns discrete geometric representations of RNA by combining vector quantization with flow matching. Our design is motivated by the modular organization of RNA architecture: complex folds are composed from recurring structural motifs. RiboSphere uses a geometric transformer encoder to produce approximately SE(3)-invariant (rotation/translation-invariant) features, which are discretized with finite scalar quantization (FSQ) into a finite vocabulary of latent codes. Conditioned on these discrete codes, a flow-matching decoder reconstructs atomic coordinates, enabling high-fidelity structure generation. We find that the learned code indices are enriched for specific RNA motifs, suggesting that the model captures motif-level compositional structure rather than acting as a purely compressive bottleneck. Across benchmarks, RiboSphere achieves strong performance in structure reconstruction (RMSD 1.25\,\AA, TM-score 0.84), and its pretrained discrete representations transfer effectively to inverse folding and RNA--ligand binding prediction, with robust generalization in data-scarce regimes.

Joint-Embedding Predictive Learning of Latent Market States in U.S. Equities
Simon Mahns, Randall Balestriero, Mido Assran
We investigate whether Joint-Embedding Predictive Architectures (JEPA) can learn useful representations of U.S. equity markets. We jointly train a permutation-invariant tokenizer that maps each trading day's unordered per-asset features to a fixed set of learned factor tokens, together with a temporal JEPA using masked prediction to obtain a compact daily market-state embedding. Our evaluations show that these embeddings are strongly associated with second-moment market structure (realized volatility, correlation concentration, effective factor dimensionality) and weakly associated with market direction. The embedding helps predict gradual recovery dynamics but not sudden stress onsets. Without any text supervision, latent regimes show statistically significant alignment with news-topic shifts.

SEMIR: Semantic Minor-Induced Representation Learning on Graphs for Visual Segmentation
Luke James Miller, Yugyung Lee
Segmenting small and sparse structures in large-scale images is fundamentally constrained by voxel-level, lattice-bound computation and extreme class imbalance--dense, full-resolution inference scales poorly and forces most pipelines to rely on fixed regionization or downsampling, coupling computational cost to image resolution and attenuating boundary evidence precisely where minority structures are most informative. We introduce \textbf{SEMIR} (\emph{Semantic Minor-Induced Representation Learning}), a representation framework that decouples inference from the native grid by learning a task-adapted, topology-preserving latent graph representation with exact decoding. \textbf{SEMIR} transforms the underlying grid graph into a compact, boundary-aligned graph minor through parameterized edge contraction, node deletion, and edge deletion, while preserving an exact lifting map from minor predictions to lattice labels. Minor construction is formalized as a few-shot structure learning problem that replaces hand-tuned preprocessing with a \emph{boundary-alignment objective}: minor parameters are learned by maximizing agreement between predicted boundary elements and target-specific semantic edges under a \emph{boundary Dice criterion}, and the induced minor is annota

ted with scale- and rotation-robust geometric and intensity descriptors and supp
orts efficient region-level inference via message passing on a graph neural netw
ork (GNN) with relational edge features. We benchmark \textbf{SEMIR} on three tu
mor segmentation datasets—\textbf{BraTS 2021}, \textbf{KiTS23}, and \textbf{LiTS
}—where targets exhibit high structural variability and distributional uncertain
ty. \textbf{SEMIR} yields consistent improvements in \emph{minority-structure Di
ce} at practical runtime. More broadly, SEMIR establishes a framework for learni
ng task-adapted, topology-preserving latent representations with exact decoding
for high-resolution structured visual data.

Synergistic Space-Vision Processing for Predicate Inference
Zhenhua Lei, Zefang Han, yu qiu
Scene graph generation (SGG) aims to parse an image into a structured graph of o
bjects and their predicates, enabling explicit relational reasoning for visual u
nderstanding.
However, prevailing methods often over-predict geometric predicates, resulting i
n scene graphs that are factually correct yet semantically shallow.
While recent works effectively attribute this phenomenon to the long-tailed data
 distribution, we identify another critical factor driving such biased predictio
n:
co-occurrence-induced representation entanglement, where geometric and non-geome
tric predicates that frequently co-occur are encoded into overly similar represe
ntations.
To this end, we introduce Dual-stream Synergistic Network (DS-Net) that models g
eometric and non-geometric predicates with two specialized streams, coupled with
 a bidirectional cross-stream fusion mechanism.
The space stream focuses on spatial and structural cues, while the vision stream
 captures fine-grained visual evidence and semantic priors.
Extensive experiments show that DS-Net consistently improves predicate inference
, achieving 1.3\% $\sim$ 6.1\% absolute gains in mR@100 on the SGGen task when i
ntegrated into existing SGG methods.
These results highlight the importance of synergistic modeling of geometric and
non-geometric predicates for generating semantically richer scene graphs.

Causal Forcing: Autoregressive Diffusion Distillation Done Right for High-Qualit
y Real-Time Interactive Video Generation
Hongzhou Zhu, Min Zhao, Guande He, Hang Su, Chongxuan Li, Jun Zhu
To achieve real-time interactive video generation, current methods distill pretr
ained bidirectional video diffusion models into few-step autoregressive (AR) mod
els, facing an *architectural gap* when full attention is replaced by causal att
ention. However, existing approaches do not bridge this gap theoretically. They
initialize the AR student via ODE distillation, which requires *frame-level inje
ctivity*, where each noisy frame must map to a unique clean frame under the PF-O
DE of an *AR teacher*. Distilling an AR student from a bidirectional teacher vio
lates this condition, preventing recovery of the teacher's flow map and instead
inducing a conditional-expectation solution, which degrades performance. To addr
ess this issue, we propose *Causal Forcing*, which uses an autoregressive teache
r for ODE initialization to bridge the architectural gap, and then applies the s
ame DMD procedure as in Self Forcing. Empirical results show that our method out
performs all baselines across all metrics, surpassing the SOTA Self Forcing by 1
9.3\% in Dynamic Degree, 8.7\% in VisionReward, and 16.7\% in Instruction Follow
ing. Project page: https://thu-ml.github.io/CausalForcing.github.io/; the code:
https://github.com/thu-ml/Causal-Forcing.

Token Sparse Attention: Efficient Long-Context Inference with Interleaved Token
Selection
Dongwon Jo, Beomseok Kang, Jiwon Song, Jae-Joon Kim
The quadratic complexity of attention remains the central bottleneck in long-con
text inference for large language models.
Prior acceleration methods either sparsify the attention map with structured pat

terns or permanently evict tokens at specific layers, which can retain irrelevant tokens or rely on irreversible early decisions despite the layer-/head-wise dynamics of token importance.
In this paper, we propose Token Sparse Attention, a lightweight and dynamic token-level sparsification mechanism that compresses per-head Q, K, V to a reduced token set during attention and then decompresses the output back to the original sequence, enabling token information to be reconsidered in subsequent layers. Furthermore, Token Sparse Attention exposes a new design point at the intersection of token selection and sparse attention. Our approach is fully compatible with dense attention implementations, including Flash Attention, and can be seamlessly composed with existing sparse attention kernels.
Experimental results show that Token Sparse Attention consistently improves accuracy–latency trade-off, achieving up to $\times$3.23 attention speedup at 128K context with less than 1\% accuracy degradation. These results demonstrate that dynamic and interleaved token-level sparsification is a complementary and effective strategy for scalable long-context inference.

MotionMAR: Multi-scale Auto-Regressive Human Motion Reconstruction from Sparse Observations

Yuhua Luo, Junsheng Zhang, Mengyin Liu, Xincheng Lin, Ming Yan, Zhudi Chen, Chenglu Wen, Lan Xu, Siqi Shen, Cheng Wang

Human motion follows a temporal hierarchical structure, transitioning from low-frequency global trajectories to high-frequency details. Inspired by the success of multi-level autoregressive models in computer vision, we propose MotionMAR, a coarse-to-fine framework for motion reconstruction from sparse observations. It first estimates the global trajectory of human motion and then gradually refines the temporal details. This architecture consists of four integrated components. The Temporal Multi-scale Tokenization (TMT) VQ-VAE encodes the data at multiple temporal resolutions, separating semantic motion from minor jitters. The Motion Autoregressive Network (MAN) operates in this latent space, predicting motion across scales. It first establishes the global structure through coarse indices and then generates finer indices to recover specific details. Meanwhile, the Scale-Aware Control (SAC) module integrates sparse tracking data to ensure the generated output aligns with actual observations. The Motion Refinement Network (MRN) subsequently smooths consecutive poses and eliminates quantization artifacts.
Experiments show that MotionMAR achieves state-of-the-art accuracy on the AMASS dataset, providing a reliable and structure-aware approach for motion reconstruction. The source code is publicly available at \url{http://www.lidarhumanmotion.net/motionmar/}.

Learnability-Driven Knowledge Assimilation for Class-Incremental Semantic Segmentation

Xinyue Zhang, Xu Zou, Wanjia Luo, Yanjie Wang, Jiahuan Zhou, Sheng Zhong, Luxin Yan

Class-incremental semantic segmentation learns new classes while retaining old ones without access to past data. Although existing methods alleviate catastrophic forgetting on old classes, new-class performance remains limited. We identify that the key bottleneck arises from low-margin regions, where the logit of the ground-truth class is close to that of the most competitive non-ground-truth class. Our theoretical analysis suggests that optimization in these regions is characterized by high second-order margin sensitivity and a small stability radius, making learning prone to class confusion.
Based on the above analysis, we propose Learnability-Driven Knowledge Assimilation (LDKA), which targets low-margin learning via three complementary optimization strategies:
(i) Progressive Margin Learning continuously reallocates pixel-wise optimization budget in a threshold-free manner, shifting emphasis from high-margin to low-margin regions;
(ii) Smooth Knowledge Distillation applies second-order sensitivity damping along the margin direction and perturbation stabilization to suppress high-frequency

updates and increase the stability radius;
(iii) Misclassification-Aware Decoupling measures inter-class confusion with a competition matrix and decouples highly competitive class representations.
Experiments show that LDKA improves mIoU on new classes while preserving performance on old classes across 9 incremental protocols.

Gradient Flow Through Diagram Expansions: Learning Regimes and Explicit Solutions

Dmitry Yarotsky, Eugene Golikov, Yaroslav Gusev

We develop a general mathematical framework to analyze scaling regimes and derive explicit analytic solutions for gradient flow (GF) in large learning problems. Our key innovation is a formal power series expansion of the loss evolution, with coefficients encoded by diagrams akin to Feynman diagrams. We show that this expansion has a well-defined large-size limit that can be used to reveal different learning phases and, in some cases, to obtain explicit solutions of the nonlinear GF. We focus on learning Canonical Polyadic (CP) decompositions of high-order tensors, and show that this model has several distinct extreme lazy and rich GF regimes such as free evolution, NTK and under- and over-parameterized mean-field. We show that these regimes depend on the parameter scaling, tensor order, and symmetry of the model in a specific and subtle way. Moreover, we propose a general approach to summing the formal loss expansion by reducing it to a PDE; in a wide range of scenarios, it turns out to be first-order and solvable by the method of characteristics. We observe a very good agreement of our theoretical predictions with experimental results.

DynaTok: Token-Based 4D Reconstruction from Partial Point Clouds

Weirong Chen, Keisuke Tateno, Hidenobu Matsuki, Michael Niemeyer, Daniel Cremers, Federico Tombari

We address 4D reconstruction from partial point cloud sequences, where depth-sensor observations are incomplete, unordered, and lack explicit temporal correspondences. This geometry-only setting is challenging due to missing observations and ambiguous dynamics. While recent progress has largely relied on image-based methods, existing point-based approaches typically focus on single objects, assume relatively complete inputs, or require explicit correspondences.
To address these limitations, we propose DynaTok, a point-based framework for correspondence-free 4D reconstruction from partial point cloud sequences without images. DynaTok encodes frames into compact latent tokens, aggregates incomplete observations over time with a Transformer-based spatiotemporal encoder, and decouples geometry and motion through residual tokens in a unified model. A flow-matching decoder then reconstructs complete, temporally consistent 4D point-cloud sequences conditioned on the latent tokens.
Experiments on object- and scene-level benchmarks demonstrate improved reconstruction quality and temporal coherence from partial point cloud observations.

VFMF: Dense Forecasting by Generating Foundation Model Features

Gabrijel Boduljak, Yushi Lan, Christian Rupprecht, Andrea Vedaldi

Forecasting by generating RGB videos is computationally expensive, often physically implausible, and not directly actionable, since it requires translation into decision-making signals. Direct modality forecasting (e.g., predicting future segmentation) produces directly actionable outputs but fails to scale due to the need for labels. Vision Foundation Model (VFM) features offer the best of both worlds: they contain actionable semantic and geometric information that can be easily decoded from the predicted features, while requiring no labels on the downstream task for training. However, almost all existing VFM feature forecasting methods regress future features from fixed number of input frames, with evaluation predominantly on short horizons matching the training setup.

We firstly show that existing regression methods struggle with forecasting from partial observations because they average over multiple plausible futures, failing to capture uncertainty in the future given the past. Interestingly, naively r

eplacing deterministic forecasting with generative flow matching does not match the sample quality of the regression model, despite being a mathematically appropriate formulation of the forecasting task. In this work, we explain why this is the case, and we show how to optimally generate foundation model features.

Our key insight is that generative modeling of VFM features requires (auto)encoding into a compact latent
space suitable for diffusion. We show that this latent space
preserves information more effectively than previously used
alternatives, such as uncompressed feature diffusion or PCA-based compression, both for forecasting and other applications, such as image generation.

Our results suggest that conditional generation
of (compressed) VFM features offers a promising and scalable foundation
for future scene forecasters.

Epistemic Gain, Aleatoric Cost: Uncertainty Decomposition in Multi-Agent Debate for Math Reasoning
Dan Qiao, Binbin Chen, Fengyu Cai, Jianlong Chen, Wenhao Li, Fuxin Jiang, Zuzhi Chen, Hongyuan Zha, Tieying Zhang, Baoxiang Wang
Multi-Agent Debate (MAD) has shown promise in improving reasoning and reducing hallucinations, yet it remains unclear how information exchange shapes individual reasoning behavior. Empirically, MAD exhibits paradoxical phenomena, including rising accuracy with increasing token entropy and marked differences between homogeneous and heterogeneous agent combinations. In this paper, we introduce a Bayesian uncertainty analysis framework for MAD, which decomposes answer-level predictive uncertainty into epistemic uncertainty and aleatoric uncertainty, corresponding to the potential gain and cost of debate. Across multiple agent configurations, we find that effective debate depends on achieving high epistemic gain under controlled aleatoric cost. Building on this insight, we design an uncertainty-guided multi-agent reinforcement learning algorithm that encourages lower aleatoric cost and more effective epistemic information utilization. Experiments show that our approach simultaneously enhances each agent's accuracy and promotes a more productive debate process, providing an operational Bayesian perspective for understanding and improving MAD.
****
On Revisiting Entropy for Identifying Mislabeled Images
Chunlei Li, Zixuan Zheng, Yilei Shi, Guanglu Dong, Pengfei Li, Jingliang Hu, Xiao Xiang Zhu, Lichao Mou
Mislabeled samples in training datasets severely degrade the performance of deep networks, as overparameterized models tend to memorize erroneous labels. We address this challenge by proposing a novel approach for mislabeled data detection that leverages training dynamics. Our method is grounded in the key observation that correctly labeled samples exhibit consistent entropy decrease during training, while mislabeled samples maintain relatively high entropy throughout the training process. Building on this insight, we introduce a signed entropy integral (SEI) statistic that captures both the magnitude and temporal trend of prediction entropy across training epochs. SEI is broadly applicable to classification networks and demonstrates particular effectiveness when integrated with contrastive language-image pretraining (CLIP) architectures. Through extensive experiments on four medical imaging datasets---a domain particularly susceptible to labeling errors due to diagnostic complexity---spanning diverse modalities and pathologies, we demonstrate that SEI achieves state-of-the-art performance in mislabeled data identification, outperforming existing methods while maintaining computational efficiency and implementation simplicity. Our code is available at https://github.com/MedAITech/SEI.
****
In-Context Learning Is Provably Bayesian Inference: A Generalization Theory for Meta-Learning
Tomoya Wakayama, Taiji Suzuki

This paper develops a finite-sample statistical theory for in-context learning (ICL), analyzed within a meta-learning framework that accommodates mixtures of diverse task types. We leverage a Bayes risk identity that separates the total ICL risk into two orthogonal components: Bayes Gap and Posterior Variance. The Bayes Gap quantifies how well the trained model approximates the Bayes-optimal in-context predictor. For a uniform-attention Transformer, we derive a non-asymptotic upper bound on this gap, which explicitly clarifies the dependence on the number of pretraining prompts and their context length. The Posterior Variance is a model-independent risk representing the intrinsic task uncertainty. Our key finding is that this term is determined solely by the difficulty of the true underlying task, while the uncertainty arising from the task mixture vanishes exponentially fast with only a few in-context examples. Together, these results provide a unified view of ICL: the uniform-attention Transformer selects the optimal meta-algorithm during pretraining and rapidly converges to the optimal algorithm for the true task at test time.

Membership Inference Attacks for Unseen Classes

Pratiksha Thaker, Neil Kale, Steven Wu, Virginia Smith

A key tool in developing safe AI models is *data auditing*, i.e., using statistical tools to determine whether harmful content may have been used in the training data of a black-box model. Unfortunately, most *membership inference attacks* (MIAs) used to perform this type of auditing themselves assume *access* to examples of harmful content from the same distribution as the query data. In real-world auditing scenarios, auditors often face legal and ethical restrictions preventing them from accessing a representative set of samples of harmful content to train MIA models effectively. We abstract and formalize this setting into a new data access model, the “unseen class” setting, and show that the state-of-the-art MIAs fail due to the lack of access to the full target distribution. We show that in this setting, *quantile regression attacks* outperform approaches typically considered to be state of the art. We demonstrate this both empirically and theoretically, showing that quantile regression attacks achieve up to **11× the TPR** of shadow model-based approaches in practice, and providing a theoretical model that outlines the generalization properties required for this approach to succeed. Our work identifies an important failure mode in existing MIAs and provides a cautionary tale for practitioners who aim to directly use existing tools for real-world applications of AI safety.

****

Jailbreak Foundry: From Papers to Runnable Attacks for Reproducible Benchmarking

Zhicheng Fang, Jingjie Zheng, Chenxu Fu, Wei Xu

Jailbreak techniques for large language models (LLMs) evolve faster than benchmarks, making robustness estimates stale and difficult to compare across papers due to drift in datasets, harnesses, and judging protocols. We introduce **JAILBREAK FOUNDRY (JBF)**, a system that addresses this gap via a multi-agent workflow to translate jailbreak papers into executable modules for immediate evaluation within a unified harness. JBF features three core components: (i) *JBF-LIB* for shared contracts and reusable utilities; (ii) *JBF-FORGE* for the multi-agent paper-to-module translation; and (iii) *JBF-EVAL* for standardizing evaluations. Across 30 reproduced attacks, JBF achieves high fidelity with a mean (reproduced$-$reported) attack success rate (ASR) deviation of $+0.26$ percentage points. By leveraging shared infrastructure, JBF reduces attack-specific implementation code by nearly half relative to original repositories and achieves an 82.5% mean reused-code ratio. This system enables a standardized AdvBench evaluation of all 30 attacks across 10 victim models using a consistent GPT-4o judge. By automating both attack integration and standardized evaluation, JBF offers a scalable solution for creating living benchmarks that keep pace with the rapidly shifting security landscape.

Induction Heads Interpolate N-Grams

Francesco D'Angelo, O■uz Kaan Yüksel, Swathi Shree Narashiman, Nicolas Flammarion

Induction heads are attention circuits believed to underlie in-context learning in transformers, yet a precise characterization of the estimators they implement remains elusive. We study transformers trained on order-k Markov chains and identify two complementary smoothing mechanisms. First, at finite attention-weight scale, the circuit implements a soft context-matching estimator: it aggregates contributions from exact and partial context matches, weighted exponentially by their overlap, and induces a data-dependent interpolation across context orders analogous to Jelinek--Mercer smoothing. Second, a beginning-of-sequence (BOS) token induces additive pseudo-counts, recovering Dirichlet-style smoothing. We construct a disentangled transformer implementing both mechanisms and show that trained transformers recover the predicted attention patterns. Across settings where pseudo-count smoothing is optimal or lower-order contexts provide structured evidence, trained transformers match or outperform classical count-based baselines. Our results bridge mechanistic interpretability of induction heads with classical statistical smoothing, revealing that transformers learn to regularize in-context estimation rather than simply count.

Concept Removal Guidance: Evidence-Calibrated Negative Guidance for Safe Diffusion Sampling

Yoonseok Choi, Chaeyoung Oh, Hyunjun Choi, Seokin Seo, Kee-Eung Kim

Text-to-image diffusion models remain vulnerable to adversarial prompts that elicit disallowed content, motivating reliable inference-time controls. A popular approach is negative guidance, which subtracts a negative prompt direction with a fixed weight. However, it often forces a safety–fidelity trade-off, causing artifacts or prompt drift when over-applied and failing under attacks when under-applied. Dynamic variants reweight guidance using posterior-odds signals, which can be brittle for open-vocabulary compositional prompts, while lightweight similarity-based methods ignore the evolving image evidence along the denoising trajectory. We introduce Concept Removal Guidance (CRG), a training-free method that estimates unwanted-concept presence at each diffusion step from the model's noise predictions, and adaptively calibrates negative guidance via a closed-form constrained update enforcing a target presence threshold while minimally perturbing the conditional trajectory. Across red-teaming benchmarks, CRG reduces attack success rates while preserving benign fidelity, and extends to additional suppression targets such as artist style and violence without fine-tuning or external classifiers.

****

PACER: Acyclic Causal Discovery from Large-scale Interventional Data

Ramon Viñas Torné, Sílvia Fábregas Salazar, Soyon Park, Ivo Ban, Artyom Gadetsky, Nikita Doikov, Maria Brbic

Inferring the structure of directed acyclic graphs (DAGs) from data is a central challenge in causal discovery, particularly in modern high-dimensional settings where large-scale interventional data are increasingly available. While interventional data can improve identifiability, existing methods remain limited by soft acyclicity constraints, leading to optimization over invalid cyclic graphs, numerical instability, and reduced scalability. We introduce PACER (Perturbation-driven Acyclic Causal Edge Recovery), a scalable framework for causal discovery that guarantees acyclicity by construction. PACER parameterizes a distribution over DAGs through a joint model of variable permutations and edge probabilities, enabling direct optimization over valid causal structures without surrogate penalties. The framework supports a unified likelihood-based treatment of observational and interventional data, flexible conditional density models, and the incorporation of structural prior knowledge. For linear-Gaussian mechanisms, we derive closed-form expressions for the expected interventional log-likelihood and its gradients, yielding substantial computational gains. Empirically, PACER matches or exceeds state-of-the-art methods on protein signaling and large-scale genetic perturbation benchmarks, while scaling efficiently to networks with thousands of variables and achieving up to two orders of magnitude speedups over penalty-based differentiable approaches. These results demonstrate that exact and scalable causal discovery from high-dimensional perturbation data is achievable through p

rincipled search space design.

Enhancing LLMs for Graph Tasks via Graph-aware LoRA Generation
Junshu Sun, Wanxing Chang, Qingming Huang, Shuhui Wang
Graph neural networks (GNNs) tightly couple their input-output parameters to dat aset-specific feature spaces and target sets, exhibiting limited transferability across different datasets. In contrast, language models (LMs) generalize flexib ly via a unified input-output interface, motivating recent attempts to adapt LMs to graph tasks. However, existing methods struggle to encode whole-graph inform ation, leading to potential information loss and suboptimal graph understanding. In this work, we propose a novel weight-level information injection paradigm fo r adapting LMs to graph tasks. This paradigm injects whole-graph information by generating task-specific weight updates that interact directly with hidden repre sentations. Instantiating this paradigm following low-rank adaptation (LoRA), we introduce GaRA, a Graph-aware LoRA generation model. GaRA constructs low-rank w eight updates conditioned on the original graph structures and constrains the no rm of the generated updates, thus injecting whole-graph information and avoiding the optimization bias in the weight generation. Empirical studies demonstrate t hat GaRA consistently outperforms baselines on zero-shot graph learning tasks.
****
DiLA: Disentangled Latent Action World Models
Tianqiu Zhang, Muyang Lyu, Yufan Zhang, Fang Fang, Si Wu
Latent Action Models (LAMs) enable the learning of world models from unlabeled v ideo by inferring abstract actions between consecutive frames. However, LAMs fac e a fundamental trade-off between action abstraction and generation fidelity. Ex isting methods typically circumvent this issue by using two-stage training with pre-trained world models or by limiting predictions to optical flow. In this pap er, we introduce *DiLA*, a novel **Di**sentangled **L**atent **A**ction world mo del that aims to resolve this trade-off via content-structure disentanglement. O ur key insight is that disentanglement and latent action learning are co-evolvin g: the predictive bottleneck inherent in latent action learning serves as a driv ing force for disentanglement, compelling the model to distill spatial layouts i nto the structure pathway while offloading visual details to a separate content pathway for generation. This synergy yields a continuous, semantically structure d latent action space without compromising generative quality. *DiLA* achieves s uperior results in video generation quality, action transfer, visual planning, a nd manifold interpretability. These findings establish *DiLA* as a unified frame work that simultaneously achieves high-level action abstraction and high-fidelit y generation, advancing the frontier of self-supervised world model learning.

From Similarity to Vulnerability: Key Collision Attack on LLM Semantic Caching
Zhixiang Zhang, Zesen Liu, Yuchong Xie, Quanfeng Huang, Dongdong She
Semantic caching has emerged as a pivotal technique for scaling LLM applications , widely adopted by providers including AWS and Microsoft. By utilizing embeddin g vectors as cache keys, this mechanism effectively minimizes latency and redund ant computation for semantically similar queries. In this work, we conceptualize semantic cache keys as a form of fuzzy hashes. We demonstrate that the locality required to maximize cache hit rates fundamentally conflicts with the cryptogra phic avalanche effect necessary for collision resistance.
Our conceptual analysis formalizes this inherent trade-off between performance (locality) and security (collision resilience), revealing that semantic caching i s inherently vulnerable to key collision attacks.
While prior research has focused on side-channel and privacy risks, we present t he first systematic study of integrity risks arising from cache collisions. We i ntroduce CacheAttack, an automated framework for launching black-box collision a ttacks.
We evaluate CacheAttack in security-critical tasks and agentic workflows. It ach ieves a hit rate of 86\% in LLM response hijacking and can induce malicious beha viors in LLM agent, while preserving strong transferability across different emb edding models.

A case study on a financial agent further illustrates the real-world impact. Finally, we discuss mitigation strategies, highlighting a persistent trade-off between cache efficiency and robustness.

MINT: Minimal Information Neuro-Symbolic Tree for Objective-Driven Knowledge-Gap Reasoning and Active Elicitation

Zeyu Fang, Mahdi Imani, Tian Lan

Joint planning through language-based interactions is a key area of human-AI teaming. Planning problems in the open world often involve various aspects of incomplete information and unknowns, e.g., objects involved, human goals/intents -- thus leading to knowledge gaps in joint planning. We consider the problem of discovering optimal interaction strategies for AI agents to actively elicit human inputs in object-driven planning. To this end, we propose Minimal Information Neuro-Symbolic Tree (MINT) to reason about the impact of knowledge gaps and leverage self-play with MINT to optimize the AI agent’s elicitation strategies and queries. More precisely, MINT builds a symbolic tree by making propositions of possible human-AI interactions and by consulting a neural planning policy to estimate the uncertainty in planning outcomes caused by remaining knowledge gaps. Finally, we leverage LLM to search and summarize MINT’s reasoning process and curate a set of queries to optimally elicit human inputs for best planning performance. By considering a family of extended Markov decision processes with knowledge gaps, we analyze the return guarantee for a given MINT with active human elicitation. Our evaluation on three benchmarks involving unseen/unknown objects of increasing realism shows that MINT-based planning attains near-expert returns by issuing a limited number of questions per task while achieving significantly improved rewards and success rates.

Bridging Structure and Semantics: Uncertainty-Modulated Dual-Path Diffusion for Robust Text-Attributed Graph Learning

Zhizhi Yu, Jiachen Liu, Qingyu Li, Dongxiao He, Di Jin

Representation learning on text-attributed graphs (TAGs) is crucial for real-world applications, as it enables effective modeling of both rich node semantics and complex graph structure. Nevertheless, this task is intrinsically challenging due to structural–semantic mismatch stemming from divergent modality distributions, as well as dual-source noise inherent in node textual content and graph structure. Existing approaches often enforce a rigid fusion of distinct modalities while overlooking their inherent noise, which inevitably results in persistent distribution gaps and amplifies mixed interference during information propagation. To address these issues, we propose UDPD, an Uncertainty-modulated Dual-Path Diffusion model for robust text-attributed graph learning. Specifically, we first employ a dual-perspective node encoding strategy to separately learn semantic and structural embeddings. We then introduce a cooperative diffusion paradigm with parallel semantic and structural branches, where mutual guidance enables progressive alignment of different distributions while effectively suppressing modality inherent noise. Crucially, the reverse process is guided by node uncertainty, which is used to adaptively modulate cross-branch interaction strength, ensuring robust coupling and maximizing denoising effectiveness. Extensive experiments on five public benchmarks demonstrate the effectiveness and superiority of our UDPD over state-of-the-art baselines.

Local Minima in Quadratic-Penalty Relaxations of Binary Linear Programs

Cheng-Han Huang, Yongliang Sun, Chaoyan Huang, Ismail Alkhouri, Rongrong Wang

Many combinatorial optimization problems admit quadratic unconstrained binary formulations (QUBO) which can often be relaxed to the box $[0,1]^n$ and optimized using scalable gradient-based methods. However, the resulting non-convex landscape can often contain local optima that are spurious or infeasible. In this paper, we establish sufficient structural conditions on quadratic penalties that rule out these failures, guaranteeing that every local minimizer of the relax problem is both binary and feasible. For each problem we study, we examine existing QUBO formulations when available, identify why they fail when they do, and propose

alternative relaxed QUBOs that satisfy our conditions. We show for several common combinatorial problems, including open-pit mining, knapsack, and traveling salesman formulations, that these constructions allow gradient-based methods such as projected gradient descent and Adam to be safely applied to obtain valid binary solutions. Our results clarify when differentiable optimization is a reliable local solver for quadratic combinatorial objectives.

Bias in Zeroth-Order Normal Estimation for Decision-Based Attacks
Feiyang Wang, Hangwei Qian, Xingquan Zuo, Gang Chen, Ivor Tsang
Decision-based image attacks commonly rely on zeroth-order (ZO) Monte Carlo probing to estimate decision-boundary normals and iteratively refine adversarial perturbations to minimize the ℓ_2 norm.
We theoretically analyze and empirically demonstrate an intrinsic inefficiency arising from heterogeneous input sensitivity, where only a small subset of coordinates strongly affects the target model’s predictions.
Empirically, with one-bit feedback and a limited query budget, updates on low-sensitivity coordinates are overwhelmed by initialization and sampling noise, preventing their perturbations from exhibiting consistent improvement.
By modeling ZO refinement as a stochastic dynamical system, we formally characterize its asymptotic behavior: the optimization enters a stationary regime, where the perturbation aligns (in expectation) with the normal and its coordinate-wise magnitudes encode a local sensitivity ranking. However, this stationarity does not generally yield ℓ_2-optimal perturbations under nonlinear boundaries.
Building on this observation, we propose a novel and effective algorithm, Sensitivity-Aware Rescaling (SAR), that leverages this sensitivity signal to infer an importance map from the current best perturbation, then progressively suppresses low-importance regions through a coarse-to-fine schedule to reduce the ℓ_2 norm.
Extensive experiments show that SAR achieves consistent improvements in perturbation norm, attack success rate, and visual imperceptibility. The code is available at https://github.com/Flyingssheep/SAR.

FairMerging: Rethinking Model Merging through the Lens of Fairness
Bing Liu, Xinrui Shan, Boyu Zhang, Qiankun Zhang, Bin Yuan, Jing Wang, Xianjun Deng
Model merging offers an appealing route to multi-task learning by composing independently fine-tuned checkpoints without centralized data or retraining. However, this convenience can come with a hidden cost. Model merging may *amplify* performance disparities across subgroups, raising fairness concerns even when average accuracy remains competitive. To explain this phenomenon, we develop a sensitivity-based theoretical analysis that upper bounds the fairness gap induced by model merging. Theoretical analysis with empirical verifications reveals that the resulting fairness gap is governed by two coupled factors, a *merging magnitude* term that measures how far the merged parameters move from the target model and *global sensitivity* terms that determine how unevenly the perturbation affects subgroup losses. Guided by these insights, we propose *FairMerging*, a two-stage merging framework that first reduces the sensitivity of the target model and then performs fairness-aware coefficient optimization with orthogonally normalized task vectors. Experiments across multiple datasets, backbones, and merging baselines demonstrate that FairMerging substantially mitigates unfairness while retaining competitive multi-task performance.

Tabero: Learning Gentle Manipulation with Closed-Loop Force Feedback from Vision, Touch, and Language
Qiwei Wu, Rui Zhang, Xin Xiang, Tao Li, Weihua Zhang, Junjie Lai, Renjing Xu
Tactile sensing is essential for robots to achieve human-like gentle manipulation. However, existing Vision-Language-Action (VLA) models struggle to exploit tactile feedback for gentle manipulation due to scarce aligned vision-tactile-language data and the lack of effective closed-loop force feedback mechanisms.
To address these challenges, we introduce Tabero, a benchmark and model suite fo

r gentle, language-conditioned robotic manipulation that demands fine-grained co
ntact force perception. First, the Tabero benchmark addresses the scarcity of ta
ctile data by presenting a data-efficient pipeline that repurposes open-source r
obot manipulation trajectories to generate diverse vision-tactile-language tasks
, and establishes a multidimensional evaluation protocol that measures task succ
ess alongside physical interaction quality. Second, we propose Tabero-VTLA, an a
rchitecture with a decoupled force-position command interface; the resulting for
ce-position commands are executed by a fixed hybrid controller to enable real-ti
me, force-aware manipulation. Evaluated on Tabero, our model maintains high task
 success while reducing average grip force by over 70\% under gentle instruction
s, demonstrating its ability to modulate interaction forces based on multimodal
experience.

Panini: Continual Learning in Token Space via Structured Memory
Shreyas Rajesh, Pavan S Holur, Mehmet Yigit Turali, Chenda Duan, Vwani Roychowdh
ury
Language models are increasingly used to reason over content they were not train
ed on, such as new documents, evolving knowledge, and user-specific data. A comm
on approach is retrieval-augmented generation (RAG), which stores verbatim docum
ents externally (as chunks) and retrieves only a relevant subset at inference ti
me for an LLM to reason over. However, this results in inefficient usage of test
-time compute (LLM repeatedly reasons over the same documents); moreover, chunk
retrieval can inject irrelevant context that increases unsupported generation. W
e propose a human-like non-parametric continual learning framework, where the ba
se model remains fixed, and learning occurs by integrating each new experience i
nto an external semantic memory state that accumulates and consolidates itself c
ontinually. We present PANINI, which realizes this by representing documents as
Generative Semantic Workspaces (GSW)—an entity- and event-aware network of quest
ion–answer (QA) pairs, sufficient for an LLM to reconstruct the experienced situ
ations and mine latent knowledge via reasoning-grounded inference chains on the
network. Given a query, PANINI only traverses the continually-updated GSW (not t
he verbatim documents or chunks), and retrieves the most likely inference chains
. Across six QA benchmarks, PANINI achieves the highest average performance, 5%–
7% higher than other competitive baselines, while using 2–30× fewer answer-conte
xt tokens, supports fully open-source pipelines, and reduces unsupported answers
 on curated unanswerable queries. The results show that efficient and accurate s
tructuring of experiences at write time—as achieved by the GSW framework—yields
both efficiency and reliability gains at read time. Code is available at https:/
/github.com/roychowdhuryresearch/gsw-memory.

Train for Truth, Keep the Skills: Binary Retrieval-Augmented Reward Mitigates Ha
llucinations
Tong Chen, Akari Asai, Luke Zettlemoyer, Hannaneh Hajishirzi, Faeze Brahman
Modern post-trained language models are increasingly capable, but remain prone t
o extrinsic hallucinations.
We target the utility degradation issue that prior hallucination-reduction metho
ds often struggle to avoid, and propose online RL with Binary Retrieval-Augmente
d Reward (Binary RAR) to reduce hallucinations while preserving general capabili
ties.
Binary RAR assigns a reward of 1 if a response contains no factual contradiction
s with retrieved evidence, and 0 otherwise.
We theoretically show that this method reduces the probability of error-containi
ng responses while preserving the distribution of error-free responses. This hel
ps preserve the model’s capabilities, whereas other methods often degrade them.
We evaluate Binary RAR on multiple widely used models. On Qwen3-8B, it reduces l
ong-form hallucination rates by 39.3\% and short-form hallucination rates by 54.
4\%, outperforming supervised learning and preference optimization baselines.
Our error analysis shows that continuous factuality rewards (e.g., VeriScore) ca
n be exploited via reward hacking by producing fewer or more generic claims, whe
reas Binary RAR is more robust and better preserves general capabilities, includ

ing instruction following, math, and coding.

Learning Permutation-invariant Macroscopic Dynamics
Zhichao Han, Mengyi Chen, Qianxiao Li
Accurately modeling the macroscopic dynamics of high-dimensional microscopic systems is of broad interest across the sciences.
Many data-driven approaches learn a low-dimensional latent state through an autoencoder trained for pointwise input reconstruction. These methods typically assume a fixed ordering of microscopic degrees of freedom in the input.
However, in many settings, such as particle systems, the microscopic state is inherently unordered.
This motivates an autoencoder framework that learns permutation-invariant latent representations.
To this end, we adopt a permutation-invariant encoder and design the decoder to reconstruct
the mass distribution centered at the observed points rather than per-sample reconstruction.
We then jointly learn the macroscopic dynamics of the observables together with the latent states.
We demonstrate the effectiveness and robustness of the proposed method across a range of microscopic settings, including learning the energy dynamics in interacting particle systems, predicting mixing dynamics in Lennard–Jones fluids, and modeling the stretching dynamics from video data of polymers moving in an elongational force field.
****
Sparse Tokens Suffice: Jailbreaking Audio Language Models via Token-Aware Gradient Optimization
Zheng Fang, Xiaosen Wang, Shenyi Zhang, Shaokang Wang, Zhijin Ge
Jailbreak attacks on audio language models (ALMs) optimize audio perturbations to elicit unsafe generations, and they typically update the entire waveform densely throughout optimization. In this work, we investigate the necessity of such dense optimization by analyzing the structure of token-aligned gradients in ALMs. We find that gradient energy is highly non-uniform across audio tokens, indicating that only a small subset of token-aligned audio regions dominates the optimization signal. Motivated by this observation, we propose Token-Aware Gradient Optimization (TAGO), which enables sparse jailbreak optimization by retaining only waveform gradients aligned with audio tokens that have high gradient energy, while masking the remaining gradients at each iteration.
Across three ALMs, TAGO outperforms baselines, and substantial sparsification preserves strong attack success rates (e.g., on Qwen3-Omni, ASR_{l} remains at 86% with a token retention ratio of 0.25, compared to 87% with full token retention). These results demonstrate that dense waveform updates are largely redundant, and we advocate that future audio jailbreak and safety alignment research should further leverage this heterogeneous token-level gradient structure.
****
HybridOM: Hybrid Physics-Based and Data-Driven Global Ocean Modeling with Efficient Regional Downscaling
Ruiqi Shu, Xiaohui Zhong, Qiusheng Huang, Ruijian Gou, Tianrun Gao, Hao Li, Xiaomeng Huang
Global ocean modeling is vital for climate science but struggles to balance computational efficiency with accuracy. Traditional numerical solvers are accurate but computationally expensive, while pure deep learning approaches, though fast, often lack physical consistency and long-term stability. To address this, we introduce HybridOM, a framework integrating a lightweight, differentiable numerical solver as a skeleton to enforce physical laws, with a neural network as the flesh to correct subgrid-scale dynamics. To enable efficient high-resolution modeling, we further introduce a physics-informed regional downscaling mechanism based on flux gating. This design achieves the inference efficiency of AI-based methods while preserving the accuracy and robustness of physical models. Extensive experiments on the GLORYS12V1 and OceanBench dataset validate HybridOM's performan

ce in two distinct regimes: long-term subseasonal-to-seasonal simulation and sho
rt-term operational forecasting coupled with the FuXi-2.0 weather model. Results
 demonstrate that HybridOM achieves state-of-the-art accuracy while maintaining
physical consistency, offering a robust solution for next-generation ocean digit
al twins.

Provably Efficient Policy-Reward Co-Pretraining for Adversarial Imitation Learni
ng

Tian Xu, Zexuan Chen, Zhilong Zhang, Yi-Chen Li, Chenyang Wang, Lei Yuan, Yang Y
u

Adversarial imitation learning (AIL) achieves high-quality imitation compared to
 behavioral cloning (BC), but demands substantial online environment interaction
. Recent empirical work has explored initializing AIL algorithms with BC-pretrai
ned policies to address this limitation, yet a rigorous theoretical understandin
g of pretraining's role in AIL remains elusive. This paper provides a systematic
 theoretical analysis and introduces principled pretraining algorithms for accel
erating AIL. We begin by analyzing AIL with policy pretraining alone, identifyin
g reward error as the dominant source of suboptimality. This reveals a critical
and previously overlooked gap: the absence of reward pretraining. Motivated by t
his finding, we develop a principled policy–reward co-pretraining approach groun
ded in a reward-shaping analysis. Our analysis uncovers a fundamental connection
 between expert policies and shaping rewards, which naturally gives rise to CoPT
-AIL, an approach that jointly pretrains both policy and reward through a single
 BC procedure. We prove that CoPT-AIL achieves an improved imitation gap bound o
ver standard AIL, establishing the first theoretical guarantee for the benefits
of pretraining in AIL. Experimental results confirm CoPT-AIL's superior performa
nce over existing AIL methods.

EmBrace: A Collective Knowledge Fusion Framework Toward Unified EEG Foundation M
odels

Ziyu Jia, Junyi Lin, Pu Wan, Jinxin Pi, Jingying Ma, Peiliang Gong, Xinliang Zho
u, Yi Ding, Chenyu Liu

Electroencephalography (EEG) foundation models (EFMs) have achieved strong perfo
rmance across a wide range of downstream EEG tasks via pretraining and fine-tuni
ng. Through empirical analysis, we observe that (i) no single EFM consistently d
ominates all tasks, yet identifying the task-specific optimal model by fine-tuni
ng all EFMs introduces substantial computational overhead; and (ii) models with
inferior task-level performance still exhibit strengths at the sample level as d
istinct architectures induce diverse inductive biases. These observations motiva
te EmBrace, a representation-centric framework for sample-aware knowledge fusion
 that avoids the constraints of parameter-level or output-level alignment. EmBra
ce synchronizes discriminative intermediate representations into a unified manif
old and adaptively weights multiple EFMs at the sample level while selecting the
 most compatible model as the carrier. Extensive experiments across multiple EEG
 benchmarks demonstrate that EmBrace consistently improves over SOTA EFMs and ge
neralizes effectively under cross-task settings.

Beyond Problem Solving: UOJ-Bench for Evaluating Code Generation, Hacking, and R
epair in Competitive Programming

Tingqiang Xu, Hangrui Zhou, Tianle Cai, Alex Gu, Kaifeng Lyu

Despite strong performance in competitive programming, the role of Large Languag
e Models (LLMs) in supporting human learning in the same setting remains largely
 unexplored. In this work, we introduce **UOJ-Bench**, a benchmark designed to e
valuate not only the problem-solving ability of LLMs, but also their ability to
identify errors in human-written code—a crucial educational activity traditional
ly supported by running test cases over online judge systems. UOJ-Bench consists
 of three distinct tasks: code generation, code hacking, and code repair, all co
nstructed from real-world code submissions on the Universal Online Judge (UOJ) a
nd evaluated through UOJ's native judging infrastructure. Our results show that
under one-shot evaluation, even the strongest models fail to identify errors in

more than 50\% of a set of submissions that have been found to be incorrect by U OJ users. While test-time scaling improves success rates to above 90\%, the subs tantial computational costs incurred from model inference limit its practicality for large-scale deployment. Despite these limitations, we find that the best-pe rforming models under test-time scaling can uncover errors in over 5\% of full-s core submissions across roughly 30 problems, suggesting that frontier LLMs can a lready provide complementary signals beyond standard judging systems. UOJ-Bench is publicly available at https://github.com/hehezhou/UOJ-Bench.

Nash Equilibria in Games with Playerwise Concave Coupling Constraints: Existence and Computation
Philip Jordan, Maryam Kamgarpour
We study the existence and computation of Nash equilibria in concave games where the players' admissible strategies are subject to shared coupling constraints. Under playerwise concavity of constraints, we prove existence of Nash equilibria . Our proof leverages topological fixed point theory and novel structural insigh ts into the contractibility of feasible sets, and relaxes strong assumptions for existence in prior work. Having established existence, we address the question of whether in the presence of coupling constraints, playerwise independent learn ing dynamics have convergence guarantees. We address this positively for the cla ss of potential games by designing a convergent algorithm. To account for the po ssibly nonconvex feasible region, we employ a log barrier regularized gradient a scent with adaptive stepsizes. Starting from an initial feasible strategy profi le and under exact gradient feedback, the proposed method converges to an $\epsi lon$-approximate constrained Nash equilibrium within $\mathcal{O}(\epsilon^{-3}) $ iterations.

PRPO: Paragraph-level Policy Optimization for Vision-Language Deepfake Detection
Tuan Nguyen, Naseem Khan, Khang Tran, Hai Phan, Issa Khalil
The rapid rise of synthetic media has made deepfake detection a critical challen ge for online safety and trust. Progress remains constrained by the scarcity of large, high-quality datasets. Although multimodal large language models (LLMs) e xhibit strong reasoning capabilities, their performance on deepfake detection is poor, often producing explanations that are misaligned with visual evidence or hallucinatory. To address this limitation, we introduce a reasoning-annotated da taset for deepfake detection and propose Paragraph-level Relative Policy Optimiz ation (PRPO), a reinforcement learning algorithm that aligns LLM reasoning with image content at the paragraph level. Experiments show that PRPO improves detect ion accuracy by a wide margin and achieves the highest reasoning score of 4.55/5 .0. Ablation studies further demonstrate that PRPO significantly outperforms GRP O under test-time conditions. These results underscore the importance of groundi ng multimodal reasoning in visual evidence to enable more reliable and interpret able deepfake detection.

Neural Minimum Weight Perfect Matching for Quantum Error Codes
Yotam Peled, David Zenati, Eliya Nachmani
Realizing the full potential of quantum computation requires Quantum Error Corre ction (QEC). QEC reduces error rates by encoding logical information across redu ndant physical qubits, enabling errors to be detected and corrected. A common de coder used for this task is Minimum Weight Perfect Matching (MWPM) a graph-based algorithm that relies on edge weights to identify the most likely error chains. In this work, we propose a data-driven decoder named Neural Minimum Weight Perf ect Matching (NMWPM). Our decoder utilizes a hybrid architecture that integrates Graph Neural Networks (GNNs) to extract local syndrome features and Transformer s to capture long-range global dependencies, which are then used to predict dyna mic edge weights for the MWPM decoder. To facilitate training through the non-di fferentiable MWPM algorithm, we formulate a novel proxy loss function that enabl es end-to-end optimization.
Our findings on the toric code under depolarizing noise demonstrate thresholds o f 17.9\% and 10.95\%, nearing the 18.9\% and 11.0\% maximum likelihood bounds, h

ighlighting the advantage of hybrid decoders that combine the predictive capabil
ities of neural networks with the algorithmic structure of classical matching.

Safety Anchor: Defending Harmful Fine-tuning via Geometric Bottlenecks
Guoxin Lu, Letian Sha, Qing Wang, Peijie Sun, ZHOU HAO, Hua Dai, Fu Xiao
The safety alignment of Large Language Models (LLMs) remains vulnerable to Harmf
ul Fine-tuning (HFT). While existing defenses impose constraints on parameters,
gradients, or internal representations, we observe that they can be effectively
circumvented under persistent HFT. Our analysis traces this failure to the inher
ent redundancy of the high-dimensional parameter space: attackers exploit optimi
zation trajectories that are orthogonal to defense constraints to restore harmfu
l capabilities while deceptively adhering to safety restrictions.
  To address this, we propose Safety Bottleneck Regularization (SBR). SBR shifts
 the defensive focus from the redundant parameter space to the unembedding layer
, which serves as a geometric bottleneck. By anchoring the final hidden states o
f harmful queries to those of the safety-aligned model, SBR enables the model to
 maintain safe responses even under persistent HFT. Extensive experiments confir
m SBR's effectiveness, demonstrating that utilizing just a single safety anchor
is sufficient to reduce the Harmful Score to $<$10 while preserving competitive
performance on benign downstream tasks. The code is available at https://github.
com/soyoaaa/SBR.

Smooth Dynamic Cutoffs for Machine Learning Interatomic Potentials
Kevin Han, Haolin Cong, Bowen Deng, Amir Barati Farimani
Machine learning interatomic potentials (MLIPs) have proven to be wildly useful
for molecular dynamics simulations, powering countless drug and materials discov
ery applications. However, MLIPs face two primary bottlenecks preventing them fr
om reaching realistic simulation scales: inference time and memory consumption.
In this work, we address both issues by challenging the long-held belief that th
e cutoff radius for the MLIP must be held to a fixed, constant value. For the fi
rst time, we introduce a **dynamic** cutoff formulation that still leads to stab
le, long timescale molecular dynamics simulation. In introducing the dynamic cut
off, we are able to induce sparsity onto the underlying atom graph by targeting
a specific number of neighbors per atom, significantly reducing both memory cons
umption and inference time. We show the effectiveness of a dynamic cutoff by imp
lementing it onto 4 state of the art MLIPs: MACE, Nequip, Orbv3, and TensorNet,
leading to **2.26x** less memory consumption and **2.04x** faster inference time
, depending on the model and atomic system. We also perform an extensive error a
nalysis and find that the dynamic cutoff models exhibit minimal accuracy dropoff
 compared to their fixed cutoff counterparts on both materials and molecular dat
asets. All model implementations and training code will be fully open sourced.

RMNP: Row-Momentum Normalized Preconditioning for Scalable Matrix-Based Optimiza
tion
Shenyang Deng, Zhuoli Ouyang, Tianyu Pang, Zihang Liu, Ruochen Jin, Shuhua Yu, Y
aoqing Yang
Preconditioned adaptive methods have gained significant attention for training d
eep neural networks, as they capture rich curvature information of the loss land
scape . The central challenge in this field lies in balancing preconditioning ef
fectiveness with computational efficiency of implementing the preconditioner. Am
ong recent advances, Muon stands out by using Newton-Schulz iteration to obtain
preconditioned updates without explicitly constructing the preconditioning matri
x. Despite its advantages, the efficiency of Muon still leaves room for further
improvement. In this paper, we introduce RMNP (Row Momentum Normalized Precondit
ioning), an optimizer that replaces Newton-Schulz iteration with a simple row-wi
se(d_{in}) ℓ_2 normalization operation, motivated by the empirical
ly observed diagonal block structure of the Transformer layerwise Hessian. We em
pirically verified that orthogonalization and row-wise(on input dim) ℓ_2 no
rmalization are asymptotically equivalent in the case of the transformer. This s
ubstitution reduces the per-iteration computational complexity from $\mathcal{O}

(mn\cdot\min(m,n))$ to $\mathcal{O}(mn)$ for an $m\times n$ weight matrix while maintaining comparable optimization performance. Theoretically, we establish convergence guarantees for RMNP in the non-convex setting that match recent results for Muon optimizers, achieving the minimax optimal complexity. Extensive experiments on large language model pretraining show that RMNP delivers competitive optimization performance compared with Muon while substantially reducing preconditioning wall-clock time. Our code is available at https://github.com/Dominator-Index/RMNP

Exploration-free Algorithms for Multi-group Mean Estimation

Ziyi Wei, Huaiyang Zhong, Xiaocheng Li

We address the problem of multi-group mean estimation, which seeks to allocate a finite sampling budget across multiple groups to obtain uniformly accurate estimates of their means. Unlike classical multi-armed bandits, whose objective is to minimize regret by identifying and exploiting the best arm, the optimal allocation in this setting requires sampling every group on the order of $\Theta(T)$ times. This fundamental distinction makes exploration-free algorithms both natural and effective. Our work makes three contributions. First, we strengthen the existing results on subgaussian variance concentration using the Hanson-Wright inequality and identify a class of strictly subgaussian distributions that yield sharper guarantees. Second, we design exploration-free non-adaptive and adaptive algorithms, and we establish tighter regret bounds than the existing results. Third, we extend the framework to contextual bandit settings, an underexplored direction, and propose algorithms that leverage side information with provable guarantees. Overall, these results position exploration-free allocation as a principled and efficient approach to multi-group mean estimation, with potential applications in experimental design, personalization, and other domains requiring accurate multi-group inference.

PhysForge: Generating Physics-Grounded 3D Assets for Interactive Virtual World

Yunhan Yang, Chunshi Wang, Junliang Ye, YANG LI, Zanxin Chen, Zehuan Huang, Yao Mu, Zhuo Chen, Chunchao Guo, Xihui Liu

Synthesizing physics-grounded 3D assets is a critical bottleneck for interactive virtual worlds and embodied AI. Existing methods predominantly focus on static geometry, overlooking the functional properties essential for interaction. We propose that interactive asset generation must be rooted in functional logic and hierarchical physics. To bridge this gap, we introduce PhysForge, a decoupled two-stage framework supported by PhysDB, a large-scale dataset of 150,000 assets with four-tier physical annotations. First, a VLM acts as a physical architect to plan a Hierarchical Physical Blueprint defining material, functional, and kinematic constraints. Second, a physics-grounded diffusion model realizes this blueprint by synthesizing high-fidelity geometry alongside precise kinematic parameters via a novel KineVoxel Injection (KVI) mechanism. Experiments demonstrate that PhysForge produces functionally plausible, simulation-ready assets, providing a robust data engine for interactive 3D content and embodied agents.

Partial Identification of Policy Values under Network Interference

Ziyan Wang, Yiran Liu, Zhiheng Zhang

Offline Policy Evaluation (OPE) aims to estimate the value of a target policy from historical logged data without interating with the environment, thereby assessing policy performance. In settings with network interference, individuals no longer satisfy the SUTVA assumption: an individual’s outcome is influenced not only by their own treatment but also by the treatments of their neighbors, which makes the definition and estimation of policy value more complex. To capture this interference mechanism, we allow all neighbors to affect individual outcomes through a unified exposure mapping, and we use a decaying higher-order neighborhood aggregation to characterize the influence of more distant neighbors. Moreover, in real-world applications, the target policy and the logging policy often do not fully overlap (non-overlap), so the policy value in non-overlap regions cannot be point-identified. To address this issue, we partially identify the policy v

alue over non-overlap regions and, under a smoothness assumption, formulate the estimation of the lower and upper bounds as a linear program, yielding valid bou nds on the offline policy value. Finally, we conduct systematic experiments on s emi-synthetic network data to validate the effectiveness and robustness of the p roposed method under network interference and limited overlap.

Certificates for Complex-Compatible Learned Cochain Laplacians
Nivar Anwer, Marien Chenaud, David Elizondo
Learning mesh-based operators from data can match training objectives while impl icitly violating algebraic consistency constraints that classical discretization s satisfy by construction. Such violations can introduce near-kernel directions, degrade conditioning as resolution increases, and distort the low-frequency spe ctral structure on which downstream solvers and diagnostics rely. This work intr oduces a low-overhead compatibility certificate for learned operator pairs, toge ther with a closed-form projection that maps a learned pair to its Frobenius-nea rest chain-compatible operator. The certificate provides an explicit distance-to -compatibility and yields perturbation bounds for the discrete operator. These b ounds imply stability guarantees for elliptic solves and for low-frequency spect ral counts, provided a spectral gap separates the kernel from the rest of the sp ectrum and boundary treatments are well posed. Experiments on standard elliptic problems show that defect-aware training prevents condition-number blow-up at hi gher resolutions, improves robustness under mesh and topological distribution sh ifts, and maintains predictive accuracy relative to unconstrained learning. Over all, these results support the use of deployment-neutral, computable algebraic c onsistency checks to detect and control failure modes that are not revealed by l oss values alone.
****
Testing For Distribution Shifts with Conditional Conformal Test Martingales
Shalev Shaer, Yarin Bar, Drew Prinster, Yaniv Romano
We propose a sequential test for distribution-shift detection that allows confor mal test martingales (CTMs) to work under a fixed, reference-conditional setting . Existing CTM detectors construct test martingales by continually growing a ref erence set with each incoming sample, using it to assess how atypical the new sa mple is relative to past observations. While this design yields anytime-valid ty pe-I error control, it suffers from test-time contamination: after a change, pos t-shift observations enter the reference set and dilute the evidence for distrib ution shift, increasing detection delay and reducing power.

In contrast, our method avoids contamination by design by comparing each new sam ple to a fixed null reference dataset. Our main technical contribution is a robu st martingale construction that remains valid conditional on the null reference data, achieved by explicitly accounting for the estimation error in the referenc e distribution induced by the finite reference set. This yields anytime-valid ty pe-I error control together with guarantees of asymptotic power one and bounded expected detection delay. Empirically, our method detects shifts faster than sta ndard CTMs, providing a powerful and reliable distribution-shift detector.

When Generalized Zero-Shot Learning Meets PU Learning: A Plug-and-Play Framework for Seen-Class Bias Mitigation
Long Tang, Keyang Pu, Yingjie Tian
Generalized Zero-Shot Learning (GZSL) suffers from severe seen-class bias, a cha llenge stemming from the label incompleteness inherent in the mixed seen–unseen test set. To address this, we propose PUFE, a unified plug-and-play post-process ing framework that recasts GZSL inference as a Positive-Unlabeled (PU) learning task by treating seen categories as positive and mixed test data as unlabeled. P UFE constructs a PU classifier in the semantic space, jointly estimating the see n-class posterior and labeling propensity via Maximum Likelihood Estimation (MLE) within a dual-head network. Furthermore, we introduce an adaptive prototype ca libration strategy that employs high-confidence pseudo-instances—identified by t he PU classifier—to explicitly align semantic prototypes with the underlying tes

t distribution. Extensive experiments demonstrate that PUFE mitigates bias and r
aises the performance of diverse GZSL baselines across multiple architectural pa
radigms, yielding gains of up to 11.2 percentage points in the harmonic mean.

What if Tomorrow is the World Cup Final? Counterfactual Time Series Forecasting
with Textual Conditions
Shuqi Gu, Yongxiang Zhao, Baoyu Jing, Kan Ren
Time series forecasting has become increasingly critical in real-world scenarios
, where future sequences are influenced not only by historical patterns but also
 by forthcoming events. In this context, forecasting must dynamically adapt to c
omplex and stochastic future conditions, which introduces fundamental challenges
 in both forecasting and evaluation. Traditional methods typically rely on histo
rical data or factual future conditions, while overlooking counterfactual scenar
ios. Furthermore, many existing approaches are restricted to simple structured c
onditions, limiting their ability to generalize to the real-world complexities.
To address these gaps, we introduce the task of counterfactual time series forec
asting with textual conditions, enabling more flexible and condition-aware forec
asting. We propose a comprehensive evaluation framework that encompasses both fa
ctual and counterfactual settings, even in the absence of ground truth time seri
es. Additionally, we present a novel text-attribution mechanism that distinguish
es mutable from immutable factors, thereby improving forecast accuracy under sop
histicated and stochastic textual conditions.

Clipped Q-Learning: Your Value Clipping Is Secretly A Robust Operator
Zhishuai Liu, Pan Xu
We study a simple yet principled modification of classical Q-learning that clips
 the value estimate in the Bellman backup by a threshold λ. The resultin
g algorithm, clipped Q-learning, is motivated by a key theoretical insight: the
clipped Bellman backup is an unbiased one-sample estimation of a robust Bellman
operator arising naturally from a transition-regularized MDP framework. This for
mulation corresponds to optimizing performance against a specific class of adver
sarial dynamics perturbations at the test time that reallocate transition probab
ility mass away from high-value states, thereby inducing conservative but stable
 decision making. Under this interpretation, clipped Q-learning can be viewed as
 tracking the fixed point of the robust Bellman equation and learning policies t
hat hedge against adversarial dynamics shifts at test time. We analyze two clipp
ed Q-learning variants with an optimistic exploration bonus and establish polyno
mial regret guarantees, demonstrating statistical efficiency. Beyond the tabular
 setting, our framework suggests that value clipping is a modular mechanism that
 can be incorporated into general value-based RL algorithms with function approx
imation. As a proof of concept, we evaluate a clipped Double DQN algorithm on a
control task and observe robustness improvements consistent with our theoretical
 predictions.

See, Act, Adapt: Active Perception for Unsupervised Cross-Domain Visual Adaptati
on via Personalized VLM-Guided Agent
Tianci Tang, Tielong Cai, Hongwei Wang, Gaoang Wang
Pre-trained perception models excel in generic image domains but degrade signifi
cantly in novel environments like indoor scenes. The conventional remedy is fine
-tuning on downstream data which incurs catastrophic forgetting of prior knowled
ge and demands costly, scene-specific annotations. We propose a paradigm shift t
hrough Sea^2 ($\textbf{Se}$e, $\textbf{A}$ct, $\textbf{A}$dapt): rather than a
dapting the perception modules themselves, we adapt how they are deployed throug
h an intelligent pose-control agent. Sea^2 keeps all perception modules frozen
, requiring no downstream labels during training, and uses only scalar perceptua
l feedback to navigate the agent toward informative viewpoints.
Specially, we transform a vision-language model (VLM) into a low-level pose cont
roller through a two-stage training pipeline: first fine-tuning it on rule-based
 exploration trajectories that systematically probe indoor scenes, and then refi
ning the policy via unsupervised reinforcement learning that constructs rewards

from the perception module’s outputs and confidence.
Unlike prior active perception methods that couple exploration with specific mod els or collect data for retraining them, Sea^2 directly leverages off-the-shel f perception models for various tasks without the need for retraining.
We conducted experiments on three visual perception tasks, including visual grou nding, segmentation and 3D box estimation, with performance improvements of 13.5 4\%, 15.92\% and 27.68\% respectively on dataset ReplicaCAD.

Pessimistic Verification for Open-Ended Math Questions
Yanxing Huang, Zihan Tang, Zejin Lin, Peng Li, Yang Liu
Automatic verification is a critical component in building math-solving agents a nd reinforcement learning, yet it often falls short in generalizability, perform ance, and cost-efficiency. Identifying that the primary bottleneck of verificati on lies in error detection capability, we propose pessimistic verification, a pa radigm of agentic workflows that rejects a solution if any of multiple parallel verifiers identifies a flaw. We further introduce progressive pessimistic verifi cation, which employs fine-grained proof decomposition to significantly enhance verification accuracy and efficiency. Our approach surpasses the performance and token efficiency of extended long chain-of-thought (long CoT) and mainstream ve rification workflows, crucially, our analysis reveals that existing benchmarks u nderestimate its effectiveness on stronger models due to inherent annotation err ors. To further validate the effectiveness of our method, we applied a verificat ion-based solving workflow on the IMO 2025 and MathArena Apex 2025 datasets, whe re the workflow with progressive pessimistic verification exhibits remarkable im provements in both efficiency and accuracy on highly challenging contest-level m ath problems with state-of-the-art models.
****
Enhancing Neural Theorem Proving via High-Quality Proof Selection and Verifier F eedback
Xiaoxue Zhu, Jilin Hu, Fuyuan Zhang, Jianyu Zhang, Yongwang Zhao
Recent advances in large language models have accelerated neural theorem proving (NTP). Isabelle is a mature and important formal theorem prover that has been w idely used in software and hardware verification. However, progress in the Isabe lle setting remains limited. Existing approaches either optimize search strategi es or train on highly imbalanced raw proof corpora. At the same time, the specia lized structure of Isabelle proofs limits the effectiveness of general-purpose d ata selection methods.
To address these challenges, we adopt a data-centric framework for neural theore m proving in Isabelle. We characterize high-quality formal proof data along thre e complementary dimensions—proof complexity, semantic coverage, and reasoning di versity (PSR)—and propose a PSR-guided data selection pipeline to construct a co mpact, high-quality training subset. In addition, we leverage verifier feedback as a dynamic data signal during inference, introducing a dynamic feedback-based prompt optimization that iteratively incorporates Isabelle verifier feedback to guide proof generation.
We construct and release a 4k high-quality Isabelle dataset based on the PSR cri terion. On the miniF2F-test, fine-tuning solely on PSR-selected data achieves 84 .8% Pass@64. When further combined with dynamic feedback–based prompt optimizati on, the full framework improves performance to 90.6% Pass@64, establishing a new state of the art for neural theorem proving in Isabelle.

Cooperative Variance Estimation and Bayesian Neural Networks for Disentangling A leatoric and Epistemic Uncertainties
Jiaxiang Yi, Miguel Anibal Bessa
Real-world data contains aleatoric uncertainty - irreducible noise arising from imperfect measurements or from incomplete knowledge about the data generation pr ocess. Mean-variance estimation networks can learn this type of uncertainty but require ad-hoc regularization strategies to avoid overfitting and are unable to predict epistemic uncertainty (model uncertainty). Conversely, Bayesian neural n etworks predict epistemic uncertainty but are notoriously difficult to train due

to the approximate nature of Bayesian inference. We propose to cooperatively tr
ain a variance estimation network with a Bayesian neural network and empirically
demonstrate that the resulting model disentangles aleatoric and epistemic uncer
tainties while improving the mean estimation. We demonstrate the effectiveness a
nd scalability of this method across a diverse range of datasets, including a ti
me-dependent heteroscedastic regression dataset we created where the aleatoric u
ncertainty is known. The proposed method is straightforward to implement, robus
t, and adaptable to various model architectures.

Memory Caching: RNNs with Growing Memory
Ali Behrouz, Zeman Li, Yuan Deng, Peilin Zhong, Meisam Razaviyayn, Vahab Mirrokn
i
Transformers have been established as the de-facto backbones for most recent adv
ances in sequence modeling, mainly due to their growing memory capacity that sca
les with the context length. While plausible for retrieval tasks, it causes quad
ratic complexity and so has motivated recent studies to explore viable subquadra
tic recurrent alternatives. Despite showing promising preliminary results in div
erse tasks, such recurrent architectures underperform Transformers in recall-int
ensive tasks, {often attributed to their fixed-size memory. In this paper, we in
troduce Memory Caching (MC), a simple yet effective technique that enhances recu
rrent models by caching checkpoints of their memory states (a.k.a. hidden states
). Memory Caching allows the effective memory capacity of RNNs to grow with sequ
ence length, offering a flexible trade-off that interpolates between the fixed m
emory ($O(L)$ complexity) of RNNs and the growing memory (
$O(L^2)$ complexity) of Transformers. We propose four variants of MC, including
gated aggregation and sparse selective mechanisms, and discuss their implicatio
ns on both linear and deep memory modules.} Our experimental results on language
modeling, and long-context understanding tasks show that MC enhances the perfor
mance of recurrent models, supporting its effectiveness. In in-context recall ta
sks, our results indicate that while Transformers still achieve the best perform
ance, our MC variants show competitive performance, close the gap with Transform
ers, and performs better than state-of-the-art recurrent models.
****
Conformal Risk-Averse Decision Making with Action Conditional Guarantee
Zihan Zhu, Shayan Kiyani, George J. Pappas, Hamed Hassani
Reliable decision making pipelines powered by machine learning models require un
certainty quantification (UQ) methods that come with explicit safety guarantees.
Conformal prediction provides such UQ by wrapping ML predictions into predictio
n sets, and recent work by Kiyani et al. (2025b) established that these sets can
be translated into optimal risk-averse decision policies -- yet only inheriting
marginal safety guarantees. We generalize and strengthen their results by (i) i
ntroducing action-conditional conformal prediction, which yields safety guarante
es conditioned explicitly on each action taken by the decision maker, (ii) showi
ng that action-conditional prediction sets serve as a proxy for the feasible dec
ision space for risk-averse decision makers aiming to optimize action-conditiona
l value-at-risk, and (iii) proposing a principled finite-sample algorithm based
on pinball-loss minimization, connecting the framework of Gibbs et al. (2025) to
action-conditional guarantees. Experiments on two real-world datasets confirm t
hat our approach significantly improves action-conditional performance over conf
ormal baselines.

LERD: Latent Event-Relational Dynamics for Neurodegenerative Classification
Yicheng Feng, Hairong Chen, Ziyu Jia, Samir Bhatt, Hengguan Huang
Alzheimer’s disease (AD) alters brain electrophysiology and disrupts multichanne
l EEG dynamics, making accurate and clinically useful EEG-based diagnosis increa
singly important for screening and disease monitoring. However, many existing ap
proaches rely on black-box classifiers and do not explicitly model the latent ev
ent timing and cross-channel coordination behind their decisions. To address the
se limitations, we propose LERD, an end-to-end Bayesian latent event--relational
dynamical system that infers latent neural events and their relational structur

e directly from multichannel EEG without event or interaction annotations. LERD combines a continuous-time event inference module with a stochastic event-generation process to capture flexible temporal patterns, while incorporating an electrophysiology-inspired dynamical prior to guide learning in a principled way. We further provide theoretical analysis that yields a tractable IVP-based KL regularizer and stability guarantees for the inferred relational dynamics. Extensive experiments on synthetic benchmarks and two real-world AD EEG cohorts demonstrate that LERD consistently outperforms strong baselines and yields physiology-aligned rate, timing, and graph summaries that help characterize group-level dynamical differences.

Local Intrinsic Dimension of Representations Predicts Alignment and Generalization in AI Models and Human Brain

Junjie Yu, Wenxiao Ma, Chen Wei, Jianyu Zhang, Haotian Deng, Zihan Deng, Quanying Liu

Recent work has found that neural networks with stronger generalization tend to exhibit higher representational alignment with one another across architectures and training paradigms. In this work, we show that models with stronger generalization also align more strongly with human neural activity. Moreover, generalization performance, model--model alignment, and model--brain alignment are all significantly correlated with each other.

We further show that these relationships can be explained by a single geometric property of learned representations: the local intrinsic dimension of embeddings. Lower local dimension is consistently associated with stronger model--model alignment, stronger model--brain alignment, and better generalization, whereas global dimension measures fail to capture these effects. Finally, we find that increasing model capacity and training data scale systematically reduces local intrinsic dimension, providing a geometric account of the benefits of scaling. Together, our results identify local intrinsic dimension as a unifying descriptor of representational convergence in artificial and biological systems.

Boosting Monocular Metric Depth Estimation via Bokeh Rendering

Hangwei Zhang, Armando Fortes, Tianyi Wei, Xingang Pan

Bokeh rendering and depth estimation share a fundamental optical connection, yet existing methods fail to fully exploit this reciprocity. Conventional bokeh pipelines rely heavily on noisy depth maps that inevitably introduce visual artifacts. Conversely, existing monocular depth models typically follow two flawed paradigms. Generative diffusion-based frameworks often lack consistent metric scale. Meanwhile, feed-forward metric depth models frequently fail in textureless or distant regions where defocus blur can provide geometric information. We propose BokehDepth, a two-stage framework that treats synthetic defocus as a supervision-free geometric signal. In the first stage, a physically grounded generative model produces calibrated bokeh stacks from a single sharp input without requiring prior depth input. Subsequently, a lightweight defocus-aware aggregation module integrates these stacks into the encoder of a depth estimation framework. This mechanism allows the model to extract consistent geometric features from the defocus dimension while keeping the decoder architecture unchanged. Experiments demonstrate that BokehDepth achieves superior visual bokeh fidelity compared to depth-dependent rendering baselines and consistently enhances the metric accuracy of state-of-the-art monocular depth models.

Inference from Quantized Data via Normal Variance-Mean Mixtures

Chenyu Gao, Zhexian Yang, Ziping Zhao

Inference from quantized data has received significant attention in recent years due to its broad applications in machine learning and signal processing. Existing likelihood-based approaches are often restricted to Gaussian assumptions or low-bit quantization settings, limiting modeling flexibility and robustness under complex data distributions. In this work, we study inference from quantized observations under the general normal variance-mean mixture (NVMM) framework, which encompasses distributions including Gaussian, t, generalized hyperbolic skew-

t, and generalized hyperbolic distributions.
Optimization under the NVMM framework is challenging because the underlying likelihood function involves multidimensional integrals that are difficult to evaluate due to multidimensional quantization and latent mixture variables. To address this difficulty, we propose an expectation conditional maximization (ECM) algorithm with latent-variable augmentations for both quantization and mixture modeling. By leveraging the conditional Gaussian structure of the NVMM family, the proposed method admits closed-form updates for all model parameters at each iteration, leading to an efficient and tractable optimization procedure. We further establish global linear convergence guarantees for the proposed ECM algorithm. Beyond basic parameter estimation, the proposed framework naturally extends to several structured learning and recovery tasks under the NVMM framework, including quantized regression, matrix completion, compressive sensing, and covariance estimation. Numerical experiments demonstrate the effectiveness and robustness of the proposed framework across a variety of quantized inference problems.

Learning-Augmented Scalable Linear Assignment Problem Optimization via Neural Dual Warm-Starts
Ilay Yavlovich, Jad Agbaria, Muhamed Mhamed, Nir Weinberger, Jose Yallouz
The Linear Assignment Problem is a fundamental combinatorial optimization task where classical exact solvers ensure optimality but suffer from an $\mathcal{O}(N^{3})$ bottleneck, while recent neural approximations struggle with scalability and exactness. We propose a learning-augmented framework that accelerates exact solvers by predicting dual variables to warm-start the search, backed by a fallback mechanism to preserve worst-case guarantees. Central to our approach is RowDualNet, a lightweight, row-independent architecture that avoids the $\mathcal{O}(N^{2})$ memory bottleneck of graph models, enabling scalable neural warm-starting up to $N=16{,}384$. Feasibility is guaranteed by construction via the Min-Trick mechanism, completely eliminating the need for costly iterative projections. Empirically, our method drastically reduces the search effort of the Jonker-Volgenant (LAPJV) algorithm, yielding robust zero-shot generalization with strict optimality and end-to-end speedups of over 2x on complex synthetic data, 1.25x on real-world tracking, and 1.5x on transportation networks.

Threshold-Guided Optimization for Visual Generative Models
Jinbin Bai, Yu Lei, Qingyu Shi, Aosong Feng, Yi Xin, Zhuoran Zhao, Fei Shen, Kaidong Yu, Xiangtai Li
Aligning large visual generative models with human feedback is often performed through pairwise preference optimization. While such approaches are conceptually simple, they fundamentally rely on annotated pairs, limiting scalability in settings where feedback is collected as independent scalar ratings. In this work, we revisit the KL-regularized alignment objective and show that the optimal policy implicitly compares each sample’s reward to an instance-specific baseline that is generally intractable. We propose a threshold-guided alignment framework that replaces this oracle baseline with a data-driven global threshold estimated from empirical score statistics. This formulation turns alignment into a binary decision task on unpaired data, enabling effective optimization directly from scalar feedback. We further incorporate a confidence weighting term to emphasize samples whose scores deviate strongly from the threshold, improving sample efficiency. Experiments across both diffusion and masked generative paradigms, spanning three test sets and five reward models, show that our method consistently improves preference alignment over previous methods. These results position our threshold-guided framework as a simple yet principled alternative for aligning visual generative models without paired comparisons.

ToMAP: Training Opponent-Aware LLM Persuaders with Theory of Mind
Peixuan Han, Zijia Liu, Jiaxuan You
Large language models (LLMs) have shown promising potential in persuasion, but existing works on training LLM persuaders are still preliminary. Notably, while humans are skilled in modeling their opponent's thoughts and opinions proactively

and dynamically, current LLMs struggle with such Theory of Mind (ToM) reasoning, resulting in limited diversity and opponent awareness. To address this limitation, we introduce Theory of Mind Augmented Persuader (**ToMAP**), a novel approach for building more flexible persuader agents by incorporating two theory of mind modules that enhance the persuader's awareness and analysis of the opponent's mental state. Specifically, we instruct the persuader to consider possible objections to the target claim, and train a module to predict the opponent’s agreement level on these objections. Experiments show that the ToMAP persuader, while containing only 3B parameters, outperforms much larger baselines, like GPT-4o, with a relative gain of 39.4% across multiple persuadee models and diverse corpora. Notably, ToMAP exhibits complex reasoning chains and reduced repetition during training, which leads to more diverse and effective arguments. These results underscore ToMAP's potential for developing more persuasive language agents. Code is available at: https://github.com/ulab-uiuc/ToMAP.

Agentic Confidence Calibration

Jiaxin Zhang, Caiming Xiong, Chien-Sheng Wu

AI agents are rapidly advancing from passive language models to autonomous systems executing complex, multi-step tasks. Yet their overconfidence in failure remains a fundamental barrier to deployment in high-stakes settings. Existing calibration methods, built for static single-turn outputs, cannot address the unique challenges of agentic systems, such as compounding errors along trajectories, uncertainty from external tools, and opaque failure modes. To address these challenges, we introduce, for the first time, the problem of Agentic Confidence Calibration and propose Holistic Trajectory Calibration (HTC), a novel diagnostic framework that extracts rich process-level features ranging from macro dynamics to micro stability across an agent's entire trajectory. Powered by a simple, interpretable model, HTC consistently surpasses strong baselines in both calibration and discrimination, across eight benchmarks, multiple LLMs, and diverse agent frameworks. Beyond performance, HTC delivers three essential advances: it provides interpretability by revealing the signals behind failure, enables transferability by applying across domains without retraining, and achieves generalization through a General Agent Calibrator (GAC) that achieves the best calibration (lowest ECE) on the out-of-domain GAIA benchmark. Together, these contributions establish a new process-centric paradigm for confidence calibration, providing a framework for diagnosing and enhancing the reliability of AI agents.

D-Judge: Disrupting Multi-Turn Jailbreaks using Semantics-Preserving Output Rewriting

Huanli Gong, Zhipeng Wei, Yu Fu, Haz Sameen Shahgir, Ananya Gupta, Yue Dong, N. Benjamin Erichson

Multi-turn jailbreak attacks pose a growing threat to large language model (LLM) safety because they exploit feedback from auxiliary judge models to iteratively refine prompts toward harmful goals. Existing defenses largely detect or block unsafe content at individual turns or at the final response, leaving the judge-driven refinement loop intact and allowing attackers to extract informative feedback from intermediate interactions. We introduce D-Judge, a semantics-preserving output rewriting defense that intervenes directly in this loop by rewriting the victim LLM’s responses before they are evaluated by the attacker’s judge. By misaligning the judge’s feedback signal without changing the meaning of the original response, D-Judge derails the attacker’s prompt-refinement process, causing subsequent queries to be optimized against a distorted signal of attack progress. To improve D-Judge’s ability to produce such rewrites, we construct a dataset of semantically equivalent response pairs that induce different judge-assigned harmfulness scores, and use it for supervised fine-tuning followed by direct preference optimization. Experiments on HarmBench show that D-Judge reduces the success rate of state-of-the-art multi-turn jailbreaks while preserving performance on benign benchmarks.

Harmonized Dual Policy Improvement for Modelic Reinforcement Learning

Guojian Zhan, Likun Wang, Feihong Zhang, Yang Guan, Shengbo Eben Li
Policy-planner bootstrapping has emerged as a powerful paradigm in model-based r einforcement learning (MBRL). We formalize this process as a dual policy improve ment mechanism synergizing: (i) exploitative improvement via off-policy Q-maxi mization, and (ii) lookahead improvement via planner alignment. While we theoret ically prove that these improvements anchor to the same optimum, practical train ing process inevitably encounters gradient disagreement. Exacerbated by approxim ation inaccuracies and non-stationary data, this disagreement induces destructiv e interference in policy updates, destabilizing the bootstrapping loop and leadi ng to suboptimal convergence. To address this, we propose harmonized dual policy improvement (HDPI), a gradient-level framework that reconciles exploitative and lookahead improvements through a harmonic optimization scheme. This scheme effe ctively maximizes the worst-case inner product between the harmonized update and the original gradients, ensuring directional consistency and stabilizing policy evolution. Extensive empirical evaluations on 14 challenging tasks from the Dee pMind Control Suite and the Humanoid-Bench demonstrate that HDPI significantly e nhances training stability and asymptotic performance, outperforming a wide rang e of strong baselines.

Geometric and Stochastic Analysis of Discontinuities in Sparse Mixture-of-Expert s
Tho Tran Huu, Huu-Tuan Nguyen, Thien-Hai Nguyen, Nhat-Tri Ho, Viet-Hoang Tran, T ho Quan, Tan Minh Nguyen
Sparse Mixture-of-Experts (SMoE) architectures are now widely deployed in state- of-the-art language and vision models, where conditional routing allows scaling to very large networks. However, this very Top-k expert selection that enables conditional routing also renders the SMoE map inherently discontinuous. In the vicinity of these discontinuity surfaces, even inputs that are arbitrarily close may activate substantially different sets of experts resulting in significantly different outputs. In this work we give a rigorous geometric and stochastic ana lysis of these discontinuities. We first classify them by order, determined by t he number of tied experts at a switching event. Using measure-theoretic slicing arguments, we establish asymptotic volume estimates for the thickened discontinu ity surfaces, showing that lower-order discontinuity sets dominate, whereas high er-order ones occupy a vanishingly small relative volume. Next, modeling random perturbations in the input space via a diffusion process, we prove that the path eventually encounter a discontinuity, and moreover that the first hit almost su rely occurs on an order-1 discontinuity with explicit finite-time probability bo unds. We further derive occupation-time bounds that quantify the duration the ra ndom path spend in the neighborhoods of each discontinuity order. These theoreti cal results imply that inputs are more likely to lie near lower order discontinu ities. Motivated by this insight, we propose a simple smoothing mechanism that c an be directly applied to existing SMoEs, softly incorporating experts near disc ontinuities; our analysis guarantees that the added computational overhead remai ns small while providing localized smoothing near discontinuities, and experimen ts across language and vision tasks show that smoothing not only enforces contin uity of the SMoE map but also enhances empirical performance.

A Very Big Video Reasoning Suite
Maijunxian Wang, Ruisi Wang, Juyi Lin, Ran Ji, Thaddäus Wiedemer, Qingying Gao, Dezhi Luo, Yaoyao Qian, Lianyu Huang, Zelong Hong, Jiahui Ge, Qianli Ma, Hang He , Yifan Zhou, Lingzi Guo, Lantao Mei, Jiachen Li, Hanwen Xing, Tianqi Zhao, Yu F engyuan, Weihang Xiao, Yizheng Jiao, Jianheng Hou, Danyang Zhang, Pengcheng Xu, Boyang ZHONG, Zehong Zhao, Gaoyun Fang, John Kitaoka, Xu Yile, Hua XU, Kenton Bl acutt, Tin Nguyen, Siyuan Song, Haoran Sun, shaoyue wen, Linyang He, Runming Wan g, Yanzhi Wang, Mengyue Yang, Ziqiao Ma, Raphaël Millière, Freda Shi, Nuno Vasco ncelos, Daniel Khashabi, Alan Yuille, Yilun Du, Ziming Liu, Dahua Lin, Ziwei Liu , Vikash Kumar, Yijiang Li, Lei Yang, Zhongang Cai, Hokin Deng
Rapid progress in video models has largely focused on visual quality, leaving th eir reasoning capabilities underexplored. Video reasoning grounds intelligence i

n spatiotemporally consistent visual environments that go beyond what text can n
aturally capture, enabling intuitive reasoning over spatiotemporal structure, su
ch as continuity, interaction, and causality. However, systematically studying v
ideo reasoning and its scaling behavior is hindered by the lack of large-scale v
ideo reasoning training data. To address this gap, we introduce the **Very Big V
ideo Reasoning (VBVR) Dataset**, an unprecedentedly large-scale resource spannin
g *200* curated reasoning tasks following a principled taxonomy, and over *one m
illion* video clips, making it approximately *three orders of magnitude* larger
than existing datasets. We further present **VBVR-Bench**, a verifiable evaluati
on framework that moves beyond model-based judging by incorporating rule-based,
human-aligned scorers, enabling reproducible and interpretable diagnosis of vide
o reasoning capabilities. Leveraging the VBVR suite, we conduct one of the first
 video reasoning **scaling studies** and observe early signs of emergent general
ization to unseen reasoning tasks. Together, VBVR lays a foundation for the next
 stage of research in generalizable video reasoning. The data, benchmark tool ki
t, and models are released publicly at **video-reason.com**.

How to Train Your Advisor: Steering Black-Box LLMs with Advisor Models
Parth Asawa, Alan Zhu, Abigail O'Neill, Matei Zaharia, Alex Dimakis, Joseph E. G
onzalez
Frontier language models are deployed as black-box services, where model weights
 cannot be modified and customization is limited to prompting.
We introduce Advisor Models, a method to train small open-weight models to gener
ate dynamic, per-instance natural language advice that improves the capabilities
 of black-box frontier models.
Advisor Models improve GPT-5.2's performance on RuleArena (Taxes) by 27.4\%, red
uce Gemini 3 Pro's steps taken in SWE agent tasks by 24.6\%, and outperform stat
ic prompt optimizers in personalizing GPT-5 to user preferences (85-100\% vs. 40
-60\%).
We also find that advisors are transferable: an advisor trained with a low-cost
student model still transfers improvements to a frontier model.
Moreover, Advisor Models are robust: we observe no degradation on other benchmar
ks than the pipeline is trained on. Our method shows how to perform parametric o
ptimization for black-box frontier models in a practical and cost-effective way.

SEAgent: Self-Evolving Computer Use Agent with Autonomous Learning from Experien
ce
Zeyi Sun, Ziyu Liu, Yuhang Zang, Yuhang Cao, Xiaoyi Dong, Tong Wu, Dahua Lin, Ji
aqi Wang
Repurposing large vision-language models (LVLMs) as computer use agents (CUAs) h
as led to substantial breakthroughs, primarily driven by human-labeled data. How
ever, these models often struggle with novel and specialized software, particula
rly in scenarios lacking human annotations. To address this challenge, we propos
e SEAgent, an agentic self-evolving framework enabling CUAs to autonomously evol
ve through interactions with unfamiliar software. Specifically, SEAgent empowers
 computer-use agents to autonomously master novel software environments via expe
riential learning, where agents explore new software, learn through iterative tr
ial-and-error, and progressively tackle auto-generated tasks organized from simp
le to complex. To achieve this goal, we design a World State Model for step-wise
 trajectory assessment, along with a Curriculum Generator that generates increas
ingly diverse and challenging tasks. The agent's policy is updated through exper
iential learning, comprised of adversarial imitation of failure actions and Grou
p Relative Policy Optimization (GRPO) on successful ones. Furthermore, we introd
uce a specialist-to-generalist training strategy that integrates individual expe
riential insights from specialist agents, facilitating the development of a stro
nger generalist CUA capable of continuous autonomous evolution. This unified age
nt ultimately achieves performance surpassing ensembles of individual specialist
 agents on their specialized software. We validate the effectiveness of SEAgent
across five professional software of OSWorld, ScienceBoard and AndroidWorld. Our
 approach achieves a significant improvement over a competitive open-source CUA,

UI-TARS. All the code and models will be made publicly available to foster further research.

UrbanMLLM: Joint Learning of Cross-view Imagery for Urban Understanding
Xin Zhang, Tianjian Ouyang, Yu Shang, Qingmin Liao, Yong Li
Comprehensive urban understanding requires integrating macroscopic spatial structure with fine-grained street-level semantics. However, existing urban Multimodal Large Language Models (MLLMs) primarily rely on satellite imagery, limiting their ability to capture detailed urban appearance and cross-view relationships. We propose \textbf{UrbanMLLM}, a unified MLLM that jointly learns from satellite and street-view imagery for cross-view urban perception and reasoning. To support this, we construct a large-scale dataset with paired cross-view urban images, geospatial alignment, and textual annotations. UrbanMLLM introduces a cross-view perceiver to explicitly model interactions between satellite and street-view representations, and adopts a structural interleaved pre-training paradigm that organizes cross-view image–text content as coherent urban documents to enhance cross-view knowledge fusion. We evaluate UrbanMLLM on 13 diverse urban understanding tasks spanning satellite, street-view, and cross-view settings. Experimental results demonstrate consistent improvements over strong open-source and proprietary MLLMs, highlighting effectiveness and scalability of UrbanMLLM for urban environment understanding.

Identifying Connectivity Distributions from Neural Dynamics Using Flows
Timothy Doyeon Kim, Ulises Pereira Obilinovic, Yiliu Wang, Eric Todd SheaBrown, Uygar Sümbül
Connectivity structure shapes neural computation, but inferring this structure from population recordings is degenerate: multiple connectivity structures can generate identical dynamics. Recent work uses low-rank recurrent neural networks (lrRNNs) to infer low-dimensional latent dynamics and connectivity from observed activity, enabling a mechanistic interpretation of the dynamics. However, standard approaches for training lrRNNs can recover spurious structures irrelevant to the underlying dynamics. We first characterize the identifiability of connectivity structures in lrRNNs and determine conditions under which a unique solution exists. To find such solutions, we develop an inference framework based on maximum entropy and continuous normalizing flows (CNFs), trained via flow matching. Instead of estimating a single connectivity matrix, our method learns a distribution over connection weights that is maximally unbiased over unidentifiable components while matching the observed dynamics. This approach captures complex yet necessary distributions such as heavy-tailed connectivity found in empirical data. We validate our method on synthetic datasets with connectivity structures that generate multistable attractors, limit cycles, and ring attractors, and demonstrate its applicability in recordings from rat frontal cortex during decision-making. Our framework shifts circuit inference from recovering connectivity to identifying which connectivity structures are computationally required, and which are artifacts of underconstrained inference.
****
Error-Driven Graph Augmentation for Mesh-Based PDE Surrogates
Xuan Minh Vuong Nguyen, Nissrine Akkari, Fabien Casenave, Jonathan Viquerat, Elie Hachem
Graph Neural Networks (GNNs) on meshes have emerged as promising surrogates for computational mechanics, but standard local message passing struggles to propagate information across unstructured meshes, leading to large errors in regions with complex physics (e.g., shocks, wakes, boundary layers). Existing approaches enlarge connectivity with long-range edges chosen *a priori* via geometric heuristics or random sampling, which lack a mechanism to prioritize high-error regions and often introduce redundant communication. We propose **MiSe-GNN**, a dual-head architecture that adaptively augments graph connectivity using model-predicted *a posteriori* errors. MiSe-GNN jointly predicts physical fields and a node-wise error indicator; the predicted error is periodically converted into a hierarchy of additional edges via an adaptive tree that links high-error nodes to spati

al pivots at multiple scales. This error-guided connectivity concentrates messag e passing where the surrogate is uncertain while keeping the graph sparse elsewh ere, yielding a transparent and physically interpretable graph-space analogue of adaptive mesh refinement. Across industrial CFD and CSD benchmarks, MiSe-GNN co nsistently improves accuracy and accuracy–compute trade-offs over strong baselin es, and qualitative analyses show that it routes communication toward physically challenging regions. These results establish *error-guided edge augmentation* a s a robust and general design principle for long-range message passing in physic s-aware GNNs.

Expert-guided Clinical Text Augmentation via Query-Based Model Collaboration

Dongkyu Cho, Miao Zhang, Gregory D Lyng, Rumi Chunara

Data augmentation is a widely used strategy to improve model robustness and gene ralization by enriching training datasets with synthetic examples. While large l anguage models (LLMs) have demonstrated strong generative capabilities for this purpose, their applications in high-stakes domains like healthcare present uniqu e challenges due to the risk of generating clinically incorrect or misleading in formation. In this work, we propose a novel query-based model collaboration fram ework that integrates expert-level domain knowledge to guide the augmentation pr ocess to preserve critical medical information. Compared to existing LLM-based a nd traditional augmentation methods, our generated data significantly improves p reservation of critical medical information and reduces hallucinations at both t he token and concept levels. Experiments on downstream clinical prediction tasks demonstrate consistent performance gains over existing augmentation methods. Th is lightweight collaborative framework addresses the gap between LLM augmentatio n potential and the safety requirements of specialized domains.

4RC: 4D Reconstruction via Conditional Querying Anytime and Anywhere

Yihang Luo, Shangchen Zhou, Yushi Lan, Xingang Pan, Chen Change Loy

We present 4RC, a unified feed-forward framework for 4D reconstruction from mono cular videos. Unlike existing methods that typically decouple motion from geomet ry or produce limited 4D attributes, such as sparse trajectories or two-view sce ne flow, 4RC learns a holistic 4D representation that jointly captures dense sce ne geometry and motion dynamics. At its core, 4RC introduces a novel encode-once , query-anywhere and anytime paradigm: a transformer backbone encodes the entire video into a compact spatio-temporal latent space, from which a conditional dec oder can efficiently query 3D geometry and motion for any query frame at any tar get timestamp. To facilitate learning, we represent per-view 4D attributes in a minimally factorized form, decomposing them into base geometry and time-dependen t relative motion. Extensive experiments demonstrate that 4RC outperforms prior methods across a wide range of 4D reconstruction tasks.

Learning What to Generate: A Reinforcement Learning-based Closed-Loop Augmentati on Framework for Person Re-identification

Xincheng Shi, Changxiao Ma, Yongfei Zhang, Yuzhuo Ma, Rongye Shi

Person re-identification (ReID) models are sensitive to long-tail nuisances (e.g ., rare viewpoints, occlusions, complex backgrounds), yet current generative aug mentation is largely open-loop: prompts/conditions are sampled heuristically wit hout verifying whether the synthesized samples improve ReID discriminability.

We introduce ReasonAug, a closed-loop framework that learns an image-conditioned instruction policy for a frozen generator, turning augmentation into a sequenti al decision problem over instruction tokens.

A Semantic Reasoning Agent (SRA) performs hierarchical planning from global sema ntics to identity-critical local cues, producing structured edit instructions wh ose utility is verified by downstream ReID feedback.

To make closed-loop optimization reliable, we propose Metric-Aligned Gated Rewar d (MAGR), which converts metric-learning objectives into a dense reward while ga ting task shaping by identity preservation to prevent reward hacking, and Struct ure-Aware Entropy (SAE), which allocates exploration per token to lock identity-critical cues while diversifying nuisance factors.

Experiments on Market-1501 and MSMT17 demonstrate state-of-the-art performance, confirming that closing the augmentation loop and learning what to generate yiel d more discriminative training data than open-loop alternatives.

Support-Proximity Augmented Diffusion Estimation for Offline Black-Box Optimizat ion
Yonghan Yang, Ye Yuan, Zipeng Sun, Linfeng Du, Bowei He, Haolun Wu, Can Chen, Xu e Liu
Offline black-box optimization aims to discover novel designs with high property scores using only a static dataset, a task fundamentally challenged by the out- of-distribution (OOD) extrapolation problem. Existing approaches typically bifur cate into inverse methods, which struggle with the ill-posed nature of mapping s cores to designs, and forward methods, which often lack the distributional expre ssivity to quantify uncertainty effectively. In this work, we propose \textbf{SP ADE} (\textbf{S}upport-\textbf{P}roximity \textbf{A}ugmented \textbf{D}iffusion \textbf{E}stimation), a novel framework that reimagines forward surrogate modeli ng through the lens of conditional generative modeling. SPADE models the forward likelihood $p(y|\boldsymbol{x})$ using a diffusion model, but with two critical enhancements to tailor it for optimization: (1) a \emph{Calibrated Diffusion Es timation} module that enforces global consistency in statistical moments and pai rwise rankings, and (2) a \emph{Support-Proximity Regularization} mechanism that implicitly internalizes the data manifold constraint $p(\boldsymbol{x})$ via kN N-based density estimation. Theoretically, we prove that our regularization is f irst-order equivalent to maximizing a Bayesian posterior with a valid design pri or. Empirically, SPADE achieves state-of-the-art performance across Design-Bench tasks and an LLM data mixture optimization benchmark. Our code is available at https://github.com/HarryYoung2018/spade.

A Unified Approach to Interpreting Knowledge Distillation for Large Language Mod els via Interactions
Qingzhuo Wang, Ruiyang Qin, Zhenxin Qin, Wen Shen, Zhihua Wei
Despite the success of knowledge distillation (KD) in Large Language Models (LLM s), the underlying mechanism behind its efficacy remains unclear. In this paper, we propose a unified approach to explore the common mechanism of various KD met hods using interactions. Specifically, we decompose the output score of the LLM into the sum of numerous interactions. Each interaction represents a nonlinear r elationship involving a set of input variables (e.g., words). Based on the decom posed interactions, we discover that the common mechanism underlying various KD methods is the sparsification of interactions, i.e., student models retain fewer interactions for inference while suppressing other interactions to zero effects . Furthermore, we discover that the performance variance across different KD met hods arises from their capabilities in handling complex interactions. A KD metho d typically yields better performance if it enables the student model to achieve higher sparsity of complex interactions. Motivated by these insights, we propos e a plug-and-play loss function called Complex Interaction Penalty (CIP) to expl icitly enforce the sparsity of complex interactions during the distillation proc ess. Extensive experiments demonstrate that integrating CIP consistently improve s the performance of diverse KD methods on both in-domain and out-of-distributio n benchmarks.

FactGuard: Agentic Video Misinformation Detection via Reinforcement Learning
Zehao Li, Hongwei Yu, Hao Jiang, Qiang Sheng, Yilong Xu, Baolong Bi, Yang Li, Zh enlong Yuan, Yujun Cai, Zhaoqi Wang
Multimodal large language models (MLLMs) have substantially advanced video misin formation detection through unified multimodal reasoning, but they often rely on fixed-depth inference and place excessive trust in internally generated assumpt ions, particularly in scenarios where critical evidence is sparse, fragmented, o r requires external verification. To address these limitations, we propose FactG uard, an agentic framework for video misinformation detection that formulates ve rification as an iterative reasoning process built upon MLLMs. FactGuard explici

tly assesses task ambiguity and selectively invokes external tools to acquire cr
itical evidence, enabling progressive refinement of reasoning trajectories. To f
urther strengthen this capability, we introduce a two-stage training strategy th
at combines domain-specific agentic supervised fine-tuning with decision-aware r
einforcement learning to optimize tool usage and calibrate risk-sensitive decisi
on making. Extensive experiments on three public benchmarks demonstrate that Fac
tGuard consistently outperforms state-of-the-art methods in both verification ac
curacy and reliability.

From Content to Knowledge: Lightning Fast Long-Video Understanding with Neural K
nowledge Representations

Yuchen Guan, Xiao Li, Zongyu Guo, Xiaoyi Zhang, Xiulian Peng, Chun Yuan, Yan Lu

We propose a new paradigm for long video understanding by treating a long video
as a Neural Knowledge Representation (NKR). NKR represents video contents neithe
r as a stream of tokens nor pre-organized databases, but as an individual small
portion of network weights attached to the VLM backbone. The NKR weights are opt
imized to encapsulate the video's semantic content via a novel Agentic Knowledge
 Distillation (AKD) process, where an agent automatically synthesizes dense desc
riptions and question-answer pairs to distill the video's knowledge into the NKR
. While AKD serves as a comprehensive, one-time encoding phase, the resulting NK
R transforms the video into a portable, reusable asset. At inference, the lightw
eight NKR is mounted onto a frozen Vision-Language Model (VLM), enabling direct,
 query-based understanding without reloading or re-encoding the original video.
This approach decouples video length from inference cost, offering high amortize
d efficiency for multi-turn video understanding. Experiments on the LVBench benc
hmark show our method achieves performance comparable to state-of-the-art approa
ches while reducing end-to-end latency by over two orders of magnitude, opening
new possibilities for interactive long-video understanding.

PRISM: Learning Realistic Depth via Physics-Grounded Noise Disentanglement with
Semantic-Geometric Collaboration

Xiujian Liang, Jiacheng Liu, Mingyang Sun, Qichen He, Anda Cheng, Cewu Lu, Jianh
ua Sun

Real-world physical sensing exhibits complex, heterogeneous noise patterns that
deviate significantly from idealized simulation, posing a fundamental bottleneck
 for sim-to-real transfer. Existing sensor modelings typically treat depth noise
 as a monolithic black-box process, overlooking the distinct physical mechanisms
 that govern different error modalities. In this work, we introduce a physics-gr
ounded paradigm that disentangles monolithic noise into two complementary modali
ties: sensing invalidation and measurement inaccuracy, enabling a tailored treat
ment of noise sources based on their physical origins. Building on this insight,
 we propose PRISM, a tripartite framework that distills 3D Visual Foundation Mod
el features as rich spatial-semantic priors for physics-based reasoning. To addr
ess the inherent sparsity and class imbalance of invalidation regions, we develo
p Hierarchical Positive-Prioritized Supervision, integrating multi-scale positiv
e-weighted objectives with a positive-preserving dynamic hard mining strategy to
 enforce precise artifact delineation. Extensive benchmarks demonstrate that PRI
SM achieves state-of-the-art fidelity in noisy depth synthesis. Furthermore, dow
nstream robotic experiments show that PRISM facilitates a 92.1% average success
rate in the real world, marking a significant improvement over monolithic baseli
nes.

NeUQI: Near-Optimal Uniform Quantization Parameter Initialization for Low-Bit LL
Ms

Li Lin, Xinyu Hu, Xiaojun Wan

Large language models (LLMs) achieve impressive performance across domains but f
ace significant challenges when deployed on consumer-grade GPUs or personal devi
ces such as laptops, due to high memory consumption and inference costs. Post-tr
aining quantization (PTQ) of LLMs offers a promising solution that reduces their
 memory footprint and decoding latency. In practice, PTQ with uniform quantizati

on representation is favored due to its efficiency and ease of deployment, as uniform quantization is widely supported by mainstream hardware and software libraries. Recent studies on low-bit uniform quantization have led to noticeable improvements in post-quantization model performance; however, they mainly focus on quantization methodologies, while the initialization of quantization parameters remains underexplored and still relies on the conventional *Min-Max formula*. In this work, we identify the limitations of the *Min-Max formula*, move beyond its constraints, and propose **NeUQI**, a method that efficiently determines near-optimal initialization for uniform quantization. Our NeUQI simplifies the joint optimization of the scale and zero-point by deriving the zero-point for a given scale, thereby reducing the problem to a scale-only optimization. Benefiting from the improved quantization parameters, our NeUQI consistently outperforms existing methods in the experiments with the LLaMA and Qwen families on various settings and tasks. Furthermore, when combined with a lightweight distillation strategy, NeUQI even achieves superior performance to PV-tuning, a considerably more resource-intensive method.

Clipping Makes Distributed and Federated Asynchronous SGD Robust to Stragglers
Samuel Erickson, Mikael Johansson
In modern machine learning, parallelization of training is an important strategy for increasing scale. Asynchronous stochastic gradient descent (ASGD), which maximally utilizes available hardware, avoids having to wait for slow workers. However, with constant step sizes, the convergence of ASGD is nonetheless negatively effected by slow workers due to large delays in updates. At the same time, it has been empirically observed in asynchronous training of deep learning models that gradient clipping ``stabilizes'' training. In this work, we provide a theoretical justification for this behavior, as we show that clipping removes the dependence of the maximum delay in the oracle complexity. We employ a sub-Weibull model of gradient noise which generalize sub-Gaussian and sub-exponential disitributions to more heavy-tailed distributions, motivated by empirical observations in deep learning. We show convergence in expectation, and for the first time in asynchronous optimization, convergence with high probability.

DocOS: Towards Proactive Document-Guided Actions in GUI Agents
Jingjing Liu, Ziye Huang, Zihao Cheng, Zeming Liu, Jiahong Wu, Yuhang Guo, Kehai Chen, Yunhong Wang, Haifeng Wang
While Graphical User Interface (GUI) agents have shown promising performance in automated device interaction, they primarily depend on static parametric knowledge from pre-training or instruction tuning. This reliance fundamentally limits their ability to handle long-tailed tasks that require explicit procedural knowledge absent from model parameters, often forcing agents to resort to inefficient and brittle trial-and-error exploration. To mitigate this limitation, we introduce Proactive Document-Guided Action for GUI agents in dynamic, open-web environments, a novel paradigm that mirrors human problem-solving by enabling agents to autonomously search for relevant documentation to resolve long-tailed tasks. To evaluate agents' capability in this paradigm, we propose DocOS, a benchmark designed to assess document-guided problem solving in fully interactive environments. DocOS requires agents to autonomously navigate a web browser, locate relevant online documentation, comprehend procedural instructions, and faithfully ground them into executable GUI actions. Extensive experiments reveal that progress is strictly constrained by dual bottlenecks: agents struggle to reliably locate relevant information during proactive search and frequently fail to faithfully ground retrieved instructions into precise actions, pointing toward document-guided interaction as a crucial pathway for enabling self-evolving GUI agents in dynamic environments.

Does a Hybrid Space-Aware Randomized Defense Improve Empirical and Certified Adversarial Robustness?

Joy Dhar, Manish Kumar Pandey, Behzad Bozorgtabar, Nayyar Zaidi, Wenyu Zhang, Wei-Hong Li, Tingting Mu, Dwarikanath Mahapatra, Mahsa Baktashmotlagh, Trung Le, Chen Chen, Sajib Mistry, Camila Gonzalez, Samira Ebrahimi Kahou, Lina Yao, Piotr Koniusz, Robert Burns Fisher, Dinh Phung, Bohyung Han, Nuno Vasconcelos, Pietro Lio

We introduce Hybrid Space-aware Stochastic Convolution Attention Noise (HySCAN), a hybrid randomized defense that helps close the long-standing gap between provable robustness under ■2 certificates and empirical robustness against strong ■∞ attacks, while maintaining strong generalization across diverse imaging benchmarks. HySCAN jointly explores complementary sources of stochasticity at both training and inference: (i) implicit weight-space randomness via stochastic-aware Random Weights, and (ii) explicit feature-space randomness via Stochastic Attention Noise Injection modules. By incorporating randomness at both the parameter and representation levels, HySCAN enables meaningful certified guarantees while improving empirical robustness in practice. Comprehensive experiments on diverse imaging datasets, e.g., CelebA, CIFAR-10, and CIFAR-100, ImageNet-1k, HAM10000, and NIH Chest X-ray, demonstrate that HySCAN outperforms existing certified and empirical defenses, improving certified robustness by up to ≈ 9.6% and empirical robustness by up to ≈ 5% without reducing clean accuracy.

SemanticNVS: Improving Semantic Scene Understanding in Generative Novel View Synthesis

Xinya Chen, Christopher Wewer, Jiahao Xie, Xinting Hu, Jan Eric Lenssen

We present SemanticNVS, a camera-conditioned multi-view diffusion model for novel view synthesis (NVS), which improves generation quality and consistency by integrating pre-trained semantic feature extractors. Existing NVS methods perform well for views near the input view, however, they tend to generate semantically implausible and distorted images under long-range camera motion, revealing severe degradation. We speculate that this degradation is due to current models failing to fully understand their conditioning or intermediate generated scene content. Here, we propose to integrate pre-trained semantic feature extractors to incorporate stronger scene semantics as conditioning to achieve high-quality generation even at distant viewpoints. We investigate two different strategies, (1) warped semantic features and (2) an alternating scheme of understanding and generation at each denoising step. Experimental results on multiple datasets demonstrate the clear qualitative and quantitative (4.69%-15.26% in FID) improvement over state-of-the-art alternatives.

****

Over-Alignment vs Over-Fitting: The Role of Feature Learning Strength in Generalization

Taesun Yeom, Taehyeok Ha, Jaeho Lee

Feature learning strength (FLS), i.e., the inverse of the effective output scaling of a model, plays a critical role in shaping the optimization dynamics of neural nets. While its impact has been extensively studied under the asymptotic regimes---both in training time and FLS---existing theory offers limited insight into how FLS affects generalization in practical settings, such as when training is stopped upon reaching a target training risk. In this work, we investigate the impact of FLS on generalization in deep networks under such practical conditions. Through empirical studies, we first uncover the emergence of an *optimal FLS* ---neither too small nor too large---that yields substantial generalization gains. This finding runs counter to the prevailing intuition that stronger feature learning universally improves generalization. To explain this phenomenon, we develop a theoretical analysis of gradient flow dynamics in two-layer ReLU nets trained with logistic loss, where FLS is controlled via initialization scale. Our main theoretical result establishes the existence of an optimal FLS arising from a trade-off between two competing effects: An excessively large FLS induces an *over-alignment* phenomenon that degrades generalization, while an overly small FLS leads to *over-fitting*.

XSkill: Continual Learning from Experience and Skills in Multimodal Agents

Guanyu Jiang, Zhaochen Su, Xiaoye Qu, Yi R. Fung
Multimodal agents can now tackle complex reasoning tasks with diverse tools, yet they still suffer from inefficient tool use and inflexible orchestration in open-ended settings. A central challenge is enabling such agents to continually improve without parameter updates by learning from past trajectories. We identify two complementary forms of reusable knowledge essential for this goal: experiences, providing concise action-level guidance for tool selection and decision making, and skills, providing structured task-level guidance for planning and tool use. To this end, we propose XSkill, a dual-stream framework for continual learning from experience and skills in multimodal agents. XSkill grounds both knowledge extraction and retrieval in visual observations. During accumulation, XSkill distills and consolidates experiences and skills from multi-path rollouts via visually grounded summarization and cross-rollout critique. During inference, it retrieves and adapts this knowledge to the current visual context and feeds usage history back into accumulation to form a continual learning loop. Evaluated on five benchmarks across diverse domains with four backbone models, XSkill consistently and substantially outperforms both tool-only and learning-based baselines. Further analysis reveals that the two knowledge streams play complementary roles in influencing the reasoning behaviors of agents and show superior zero-shot generalization. Code is available at https://github.com/XSkill-Agent/XSkill.

InteractComp: Evaluating Search Agents With Ambiguous Queries
Mingyi Deng, Lijun Huang, Yani Fan, Fanqi Kong, Jiayi Zhang, Fashen Ren, Jinyi Bai, Fuzhen Yang, Dayi Miao, Zhaoyang Yu, Yifan Wu, Yanfei Zhang, Fengwei Teng, Yingjia Wan, Song Hu, Yude Li, Xin Jin, Conghao Hu, Haoyu Li, Qirui Fu, Tai Zhong, Xinyu Wang, Xiangru Tang, Nan Tang, Chenglin Wu, Yuyu Luo
Language agents have demonstrated remarkable potential in web search and information retrieval. However, many search-agent benchmarks assume that user queries are complete and unambiguous. This assumption leaves under-tested a practical failure mode: agents may face ambiguous requests where the intended target cannot be identified without clarification. Yet most agents lack interactive mechanisms during the search process, and existing benchmarks cannot assess this capability. To address this gap, we introduce InteractComp, a benchmark designed to evaluate whether search agents can recognize query ambiguity and actively interact to resolve it during search. Following the principle of easy to verify, interact to disambiguate, we construct 210 expert-curated questions across 9 domains through a target-distractor methodology that creates controlled ambiguity resolvable only through interaction. Evaluation of 17 models reveals striking failure: the best model achieves only 13.73% accuracy despite 71.50% with complete context, exposing systematic overconfidence rather than reasoning deficits. Forced interaction produces dramatic gains, demonstrating latent capability current strategies fail to engage. Longitudinal analysis shows interaction capabilities stagnated over 15 months while search performance improved seven-fold, revealing a critical blind spot. This stagnation, coupled with the immediate feedback inherent to search tasks, makes InteractComp a valuable resource for both evaluating and training interaction capabilities in search agents. The code is available at https://github.com/FoundationAgents/InteractComp

Embedding-perturbed Exploration Preference Optimization for Flow Models
Sujie Hu, Chubin Chen, Jiashu Zhu, Jiahong Wu, Xiangxiang Chu, Xiu Li
Recent advancements have established Reinforcement Learning (RL) as a pivotal paradigm for aligning generative models with human intent. However, group-based optimization frameworks (e.g., GRPO) face a critical limitation: *the rapid decay of intra-group variance*. As the distinctiveness among samples within a group diminishes, the variance approaches zero. This eliminates the very learning signal required for optimization, rendering the process unstable and forcing the policy into *premature stagnation or reward hacking*. Existing strategies, such as varying the initial noise or increasing group sizes, often fail to address this fundamental issue, resulting in *training instability or diminishing returns*. To overcome these challenges, we propose **Embedding-perturbed Exploration Pref

erence Optimization (E^2PO)**, a novel framework that sustains optimization th
rough embedding-level perturbation. Our method introduces structured, embedding-
level perturbations within sample groups, guaranteeing a robust variance that pr
eserves the discriminative signal throughout the training process. Extensive exp
eriments demonstrate that our approach significantly outperforms state-of-the-ar
t baselines, achieving a more faithful alignment with human preference.

SVL: Empowering Spiking Neural Networks for Efficient 3D Open-World Understandin
g

Xuerui Qiu, Shaowei Gu, Peixi Wu, JiaKui Hu, Yaozhi Wen, Yuqi Pan, Xinhao Luo, B
o XU, Guoqi Li

Spiking Neural Networks (SNNs) offer an energy--efficient route to 3D spatio--te
mporal perception, yet they lag behind Artificial Neural Networks (ANNs) due to
weak pretraining and heavy inference stacks, limiting generalization and multimo
dal reasoning (e.g., zero--shot 3D classification and open--world QA). We presen
t a universal \textbf{S}pike--based \textbf{V}ision--\textbf{L}anguage pretraini
ng framework (SVL) that equips SNNs with open--world 3D understanding while pres
erving end--to--end spike efficiency. SVL comprises two core components: (i) {Mu
lti--scale Triple Alignment} (MTA), a label--free triplet contrastive objective
aligning 3D, image, and text; and (ii) {Re--parameterizable Vision--Language Int
egration} (Rep--VLI), which converts offline text embeddings into lightweight we
ights for text--encoder--free inference. Moreover, we present the first fully sp
ike--driven point Transformer, {Spike-driven PointFormer}, whose 3D spike--drive
n self--attention (3D-SDSA) reduces interactions to sparse additions, enabling f
aster, more efficient training. Extensive experiments show that SVL attains stro
ng zero--shot 3D classification (85.4% top--1) and consistently outperforms prio
r SNNs on downstream tasks (e.g., +6.1% 3D cls, +2.1% DVS actions, +1.1% detecti
on, +2.1% segmentation) while enabling open--world 3D question answering, someti
mes outperforming ANNs. To the best of our knowledge, SVL represents the first s
calable, generalizable, and hardware-friendly paradigm for 3D open-world underst
anding, effectively bridging the gap between SNNs and ANNs in complex open-world
 understanding tasks.

CELL: A Causal Perspective for Fairness-aware Graph Adaptation

Hourun Li, Yifan Wang, Qinghua Ran, Junyu Luo, Jia Yang, Changling Zhou, Zhiping
 Xiao, Wei Ju, Xiao Luo, Ming Zhang

This paper studies fairness-aware graph adaptation, aiming to transfer knowledge
 from a labeled source graph to an unlabeled target graph while addressing fairn
ess.

Most prior methods require target-domain attributes to learn invariant graph rep
resentations of sensitive attributes, which are often unavailable in practice.

To address this limitation, we introduce \underline{C}ausality-attended Repres\u
nderline{e}ntation Dientang\underline{l}ement with Structural A\underline{l}ignm
ent (CELL) for fairness-aware graph adaptation without requiring target sensitiv
e labels.

CELL constructs a causal graph to model the graph-generation mechanism and guide
 fair representation disentanglement.

Specifically, CELL uses sensitive and causal encoders to extract sensitive and c
ausal factors, respectively, and promotes disentanglement by minimizing their co
nditional mutual information.

To leverage unlabeled target data, we further generate pseudo-labels for both ta
rget task labels and sensitive attributes, and use similarity relations to deriv
e unbiased node representations.

Finally, to further mitigate domain shift, we build a fairness-aware bipartite g
raph that provides additional structural supervision for cross-domain alignment.

Experiments on benchmarks show that CELL consistently outperforms strong baselin
es in both predictive performance and fairness.

Transformers Provably Learn Algorithmic Solutions for Graph Connectivity, But On

ly with the Right Data
Qilin Ye, Deqing Fu, Robin Jia, Vatsal Sharan
Transformers often fail to learn generalizable algorithms, instead relying on br
ittle heuristics.
Using graph connectivity as a testbed, we explain this phenomenon both theoretic
ally and empirically.
We consider a simplified Transformer architecture, the Disentangled Transformer,
 and prove that an L-layer model can compute connectivity in graphs with diame
ters up to 3^L, implementing an algorithm equivalent to computing powers of th
e adjacency matrix.
By analyzing training dynamics, we prove that whether the model learns this stra
tegy hinges on whether most training instances are within this model capacity. W
ithin-capacity graphs (diameter $\leq 3^L$) drive the learning of the algorithmi
c solution while beyond-capacity graphs drive the learning of a simple heuristic
 based on node degrees.
Finally, we empirically show that our insights transfer to standard Transformers
:
restricting training data to stay within a model's capacity makes both standard
and Disentangled Transformers learn the exact algorithm.
****
BAS: Bridging Adam and SignSGD for Memory-Efficient LLM Training
Yijie Zhou, Mingliang Zhang, Jiaqi Zhang, Xunliang Cai, Shi Pu
We propose **Block Adaptive Signum (BAS)**, which bridges Adam and SignSGD via b
lock-wise scaling of sign updates. By discarding element-wise second moments, BA
S reduces memory overhead relative to AdamW without sacrificing performance in o
ur tested settings. Crucially, BAS mimics Adam’s dynamics closely enough to dire
ctly **inherit its hyperparameters**, matching the performance of AdamW without
the need for re■tuning, a common fragility of prior low■memory optimizers. This
structural alignment makes it particularly suitable for tuning Adam-pretrained m
odels. Furthermore, we exploit the inherent robustness of sign-based updates to
store the first moment in FP8 without performance degradation. This shrinks the
optimizer■state footprint to **12.5\% of AdamW’s**. We theoretically prove conve
rgence under standard assumptions and introduce a communication-efficient varian
t enabled by the sign-based update. Across extensive evaluations, including pre■
training a 1.5B model on 100B tokens and supervised fine-tuning of models up to
32B parameters, we demonstrate that BAS achieves performance on par with AdamW.
****
LLM-Guided Diagnostic Evidence Alignment for Medical Vision–Language Pretraining
 under Limited Pairing
Huimin Yan, Liang Bai, Xian Yang, Long Chen
Most existing CLIP-style medical vision--language pretraining methods rely on gl
obal or local alignment with substantial paired data. However, global alignment
is easily dominated by non-diagnostic information, while local alignment fails t
o integrate key diagnostic evidence. As a result, learning reliable diagnostic r
epresentations becomes difficult, which limits their applicability in medical sc
enarios with limited paired data. To address this issue, we propose an LLM-Guide
d Diagnostic Evidence Alignment method (LGDEA), which shifts the pretraining obj
ective toward evidence-level alignment that is more consistent with the medical
diagnostic process. Specifically, we leverage LLMs to extract key diagnostic evi
dence from radiology reports and construct a shared diagnostic evidence space, e
nabling evidence-aware cross-modal alignment and allowing LGDEA to effectively e
xploit abundant unpaired medical images and reports, thereby substantially allev
iating the reliance on paired data. Extensive experimental results demonstrate t
hat our method achieves consistent and significant improvements on phrase ground
ing, image--text retrieval, and zero-shot classification, and even rivals pretra
ining methods that rely on substantial paired data.

Reward and Guidance through Rubrics: Promoting Exploration to Improve Multi-Doma
in Reasoning
Baolong Bi, Shenghua Liu, Yiwei Wang, Siqian Tong, Lingrui Mei, Yuyao Ge, Yilong

Xu, Jiafeng Guo, Xueqi Cheng
Recent advances in reinforcement learning (RL) have significantly improved the complex reasoning capabilities of large language models (LLMs).
Despite these successes, existing methods mainly focus on single-domain RL (e.g., mathematics) with verifiable rewards (RLVR), and their reliance on purely online RL frameworks restricts the exploration space, thereby limiting reasoning performance.
In this paper, we address these limitations by leveraging rubrics to provide both fine-grained reward signals and offline guidance.
We propose $\textbf{RGR-GRPO}$ (Reward and Guidance through Rubrics), a rubric-driven RL framework for multi-domain reasoning.
RGR-GRPO enables LLMs to receive dense and informative rewards while exploring a larger solution space during GRPO training.
Extensive experiments across 14 benchmarks spanning multiple domains demonstrate that RGR-GRPO consistently outperforms RL methods that rely solely on alternative reward schemes or offline guidance.
Compared with verifiable online RL baseline, RGR-GRPO achieves average improvements of +7.0%, +5.4%, +8.4%, and +6.6% on mathematics, physics, chemistry, and general reasoning tasks, respectively.
Notably, RGR-GRPO maintains stable entropy fluctuations during off-policy training and achieves superior pass@k performance, reflecting sustained exploration and effective breakthrough beyond existing performance bottlenecks.

Unifying Heterogeneous Multi-Modal Remote Sensing Detection Via Language-Pivoted Pretraining
Yuxuan Li, Yuming Chen, Yunheng Li, Ming-Ming Cheng, Xiang Li, jian Yang
Heterogeneous multi-modal remote sensing object detection aims to accurately detect objects from diverse sensors (e.g., RGB, SAR, Infrared). Existing approaches largely adopt a late alignment paradigm, in which modality alignment and task-specific optimization are entangled during downstream fine-tuning. This tight coupling complicates optimization and often results in unstable training and suboptimal generalization. To address these limitations, we propose BabelRS, a unified language-pivoted pretraining framework that explicitly decouples modality alignment from downstream task learning. BabelRS comprises two key components: Concept-Shared Instruction Aligning (CSIA) and Layerwise Visual-Semantic Annealing (LVSA). CSIA aligns each sensor modality to a shared set of linguistic concepts, using language as a semantic pivot to bridge heterogeneous visual representations. To further mitigate the granularity mismatch between high-level language representations and dense detection objectives, LVSA progressively aggregates multi-scale visual features to provide fine-grained semantic guidance. Extensive experiments demonstrate that BabelRS stabilizes training and consistently outperforms state-of-the-art methods without bells and whistles. Code: \href{https://github.com/zcablii/SM3Det}{github.com/zcablii/SM3Det}.

Beyond ReLU: Bifurcation, Oversmoothing, and Topological Priors
Erkan Turan, Gaspard Abel, Maysam Behmanesh, Emery Pierson, Maks Ovsjanikov
Graph Neural Networks (GNNs) learn node representations through iterative network-based message-passing. While powerful, deep GNNs suffer from oversmoothing, where node features converge to a homogeneous, non-informative state. We re-frame this problem of representational collapse from a \emph{bifurcation theory} perspective, characterizing oversmoothing as convergence to a stable ``homogeneous fixed point.'' Our central contribution is the theoretical discovery that this undesired stability can be broken by replacing standard monotone activations (e.g., ReLU) with a class of functions. Using Lyapunov-Schmidt reduction, we analytically prove that this substitution induces a bifurcation that destabilizes the homogeneous state and creates a new pair of stable, non-homogeneous \emph{patterns} that provably resist oversmoothing. Our theory predicts a precise, nontrivial scaling law for the amplitude of these emergent patterns, which we quantitatively validate in experiments. Finally, we demonstrate the practical utility of our theory by deriving a closed-form, bifurcation-aware initialization and showing it

s utility in real benchmark experiments.
****
GPan-LoRA: Gaussian Process Amortized Networks for Bayesian Low-Rank Adaptation in Large Language Models
Weifeng Zhang, Wenyuan Zhao, Amir Hossein Rahmati, Yucheng Wang, Zhiyuan Wang, Chao Tian, Xiaoning Qian
Principled uncertainty quantification (UQ) is increasingly recognized as essential for trustworthy artificial general intelligence (AGI). Bayesian Low-Rank Adaptation (LoRA) provides a principled mechanism for uncertainty-aware fine-tuning of large language models (LLMs). However, existing techniques either face scalability constraints, e.g. Laplace-LoRA, or rely on approximate inference schemes that lead to poorly calibrated posterior uncertainty, often manifesting as overconfident predictions under distribution shift. To address this challenge, we propose GPan-LoRA, the first scalable Gaussian Process (GP)-based framework for Bayesian LoRA, which integrates neural network-based sparse GP approximations with amortized variational inference. By preserving the Bayesian function prior and posterior semantics intrinsic to GPs, GPan-LoRA achieves a faithful balance between computational scalability and principled UQ. Empirically, GPan-LoRA produces well-calibrated uncertainty that remains reliable under distribution shift, mitigating overconfident failures while preserving competitive task performance.

See the Emotion: A Facial Emoji Proxy Modeling for EEG Emotion Recognition
Jingjing Hu, Dan Guo, Haofan Cheng, Zeng ying, Zhan Si, Jinxing Zhou, Meng Wang
Despite the high accuracy of EEG-based emotion recognition, existing models remain opaque "black boxes", lacking semantic grounding between abstract neural features and human-interpretable states. In this paper, we reframe EEG explainability as a cross-modal generation task, shifting the paradigm from feature attribution to behavioral visualization. We introduce Facial Emoji Proxy Modeling, a novel framework that translates high-dimensional EEG signals into identity-anonymized facial emojis. Guided by the neuroscientific inspiration of neural-facial association, this approach grounds neural representations in the manifold of observable facial dynamics. Technically, our framework integrates FMENet, a specialized backbone modeling expression-relevant spatial synergies, and the Facial Emoji Learning Branch (FELB), which treats emoji reconstruction as a structured semantic regularizer. Extensive experiments on EAV and MMER benchmarks demonstrate that our method achieves state-of-the-art accuracy among EEG-only models. Crucially, it generates semantically faithful facial animations that provide a transparent, privacy-preserving window into the brain's emotional evolution, effectively allowing users to ``see the emotion'' directly from neural signals. Code is available at https://github.com/xian-sh/SeeEmotion

PESD-TSF: A Period-Aware and Explicit Structured Decomposition Framework for Long-Term Time Series Forecasting
Hua Wang, Xianhao Jiao, Fan Zhang
Deep forecasting models often suffer from attenuated periodic perception and entangled trend–noise representations as network depth increases. Moreover, the widely adopted channel-independent paradigm, while improving training stability, disrupts intrinsic dynamic coordination among variables, hindering the modeling of cross-variable consistency in multivariate time series. To address these issues, we propose PESD-TSF, a physics-inspired structured decomposition framework for long-term time series forecasting that jointly emphasizes interpretability and predictive accuracy. PESD-TSF introduces three key designs. First, a Multiplicative Periodic Gating mechanism incorporates continuous-time priors to dynamically modulate signal amplitudes, preserving periodic structures across deep layers. Second, a multi-scale structured encoder integrates detrended attention with hierarchical sampling to explicitly decouple long-term trends from high-frequency variations while retaining fine-grained temporal semantics. Third, to recover disrupted inter-variable dependencies, we propose Cross-Scale Collaborative Attention (CSCA) together with an RLC regularization scheme, which reconstructs global inter-variable topology in deep feature spaces and enforces physically consisten

t collaboration through orthogonality and consistency constraints. Extensive exp eriments on benchmark datasets from multiple domains demonstrate that PESD-TSF c onsistently achieves state-of-the-art performance, with particularly strong gain s on multivariate forecasting tasks involving complex inter-variable coupling, h ighlighting its superior structural modeling capability and generalization.

How to Price Data: A Market Equilibrium Based Approach
Pooja Ravi Kulkarni, Parnian Shahkar, Ruta Mehta
High-quality data is a key input to modern machine learning models, leading to t he emergence of platforms that facilitate the buying and selling of data. A cent ral challenge in these platforms is how the data is priced to balance the intere sts of both buyers and sellers. Traditional market equilibrium notions, where de mand meets supply are commonly used to price goods but do not extend naturally t o data due to its non-rivalrous nature, whereby multiple buyers can simultaneous ly benefit from the same dataset. We therefore introduce a new notion of equilib rium for data pricing based on Nash equilibrium and study it in settings where d ata may be complementary or substitutable, focusing on the canonical utility mod els for each, namely Leontief and linear, respectively. We show that equilibrium prices fail to exist for linear utilities even with homogeneous buyers and two sellers, while establishing strong existence, efficiency, and polynomial-time co mputation guarantees for Leontief utilities in general markets with n homogene ous buyers and m sellers. We further examine the role of platform mediation an d price discrimination in enabling *optimal* equilibrium outcomes efficiently. O n the technical front, we develop a novel proof technique based on systematicall y reducing the space of candidate equilibria through the *graph-of-deviations*, which may be of independent interest.

Graph-GRPO: Training Graph Flow Models with Reinforcement Learning
Baoheng Zhu, Deyu Bo, Delvin Ce Zhang, Xiao Wang
Graph generation is a fundamental task with broad applications, such as drug dis covery.
Recently, discrete flow matching-based graph generation, a.k.a., graph flow mode l (GFM), has emerged due to its superior performance and flexible sampling.
However, effectively aligning GFMs with complex human preferences or task-specif ic objectives remains a significant challenge.
In this paper, we propose Graph-GRPO, an online reinforcement learning (RL) fram ework for training GFMs under verifiable rewards.
Our method makes two key contributions:
(1) We derive an analytical expression for the transition probability of GFMs, r eplacing the Monte Carlo sampling and enabling fully differentiable rollouts for RL training;
(2) We propose a refinement strategy that randomly perturbs specific nodes and e dges in a graph, and regenerates them, allowing for localized exploration and se lf-improvement of generation quality.
Extensive experiments on both synthetic and real datasets demonstrate the effect iveness of Graph-GRPO.
With only 50 denoising steps, our method achieves 95.0\% and 97.5\% Valid-Unique -Novelty scores on the planar and tree datasets, respectively.
Moreover, Graph-GRPO achieves state-of-the-art performance on the molecular opti mization tasks, outperforming graph-based and fragment-based RL methods as well as classic genetic algorithms.
Code is available in https://github.com/Zhubaoheng/Graph-GRPO.

Towards Steering without Sacrifice: Principled Training of Steering Vectors for Prompt-only Interventions
Yuntai Bao, Qinfeng Li, Xinyan Yu, Ge Su, Wenqi Zhang, Liu Yan, Haiqin Weng, Jia nwei Yin, Xuhong Zhang
Recently, *steering vectors (SVs)* have emerged as an effective and lightweight approach to steer behaviors of large language models (LLMs), among which fine-tu ned SVs are more effective than optimization-free ones.

However, current approaches to fine-tuned SVs suffer from two limitations.
First, they require careful selection of steering factors on a per-SV basis to b alance steering effectiveness and generation quality at inference time.
Second, they operate as *full-sequence SVs (FSSVs)*, which can sacrifice generat ion quality regardless of factor selection due to excessive intervention on the model generation process.
To address the first limitation, we propose *joint training* of steering factors and directions, such that post-hoc factor selection is no longer required.
Using neural network scaling theory, we find that moderately large initializatio n sizes and learning rates for steering factors are essential for stability and efficiency of joint training.
To tackle the second limitation, we draw inspiration from *representation fine-t uning* and introduce **Prompt-Only Steering Vector (PrOSV)**, an SV that interve nes only on a few prompt tokens.
Our empirical results show that PrOSV outperforms traditional FSSVs on AxBench w hen using our joint training scheme.
We also find that PrOSV achieves a better tradeoff between general model utility and adversarial robustness than FSSV.

CHESS: Chebyshev Spectral Synthesis for Trajectory Condensation
Ruituo Wu, Hongyu Zhang, Qiang Wang, Jiawei Du, Wei Cui, Ce Zhu, Bing Li
Learning from continuous-time trajectories requires modeling multivariate sensor measurements generated by underlying physical or dynamical processes. Under ext reme data compression and heterogeneous sampling, directly optimizing synthetic signals as discrete sample values becomes fundamentally misaligned with the unde rlining \emph{continuous-time physical processes}, often producing high-frequenc y, non-physical artifacts that overfit specific models and break reuse across ar chitectures and sampling rates. We propose CHESS, a \emph{function-first} synthe sis framework shifts optimization from discrete samples to underlying continuous -time signal trajectories. CHESS injects physics-induced structure by jointly en forcing low-rank spatial coherence and piecewise Chebyshev polynomial temporal p arameterization, constraining synthesis to a physically meaningful function mani fold. We provide theoretical analysis establishing explicit smoothness and stabi lity guaranties. Experiments on diverse sensor testbeds under the dataset distil lation protocol demonstrate CHESS consistently outperform state-of-the-art metho ds with a compression ratios up to $133\times$ for each synthetic sample. Furthe rmore, CHESS exhibits strong cross-architecture generalization and enables zero-shot adaptation across different sampling resolutions.

AVTrack: Audio-Visual Tracking in Human-centric Complex Scenes
Yaoting Wang, Yun Zhou, Zipei Zhang, Henghui Ding
Audio-visual speaker tracking aims to localize and track active speakers by leve raging auditory and visual cues, enabling fine-grained, human-centric scene unde rstanding.
This capability is essential for real-world applications such as intelligent vid eo editing, surveillance, and human–computer interaction.
However, existing datasets are largely limited to simple or homogeneous audio-vi sual scenes with
coarse annotations.
Such oversimplified settings bias evaluation toward static audio–visual co-occur rence, rather than rigorously assessing robust spatiotemporal modeling and cross -modal reasoning in complex, dynamic scenes.
To address these limitations, we introduce **AVTrack**, a human-centric audio-vi sual instance segmentation (AVIS) dataset designed for dynamic real-world scenar ios.
AVTrack features *diverse and challenging conditions*, including camera motion, visual occlusions, and position changes.
Evaluations of representative AVIS methods on AVTrack reveal substantial perform ance degradation, establishing AVTrack as a challenging benchmark for robust hum an-centric audio-visual scene understanding in complex environments.

We further provide a simple yet effective baseline to facilitate future research. Project website: https://FudanCVL.github.io/AVTrack/

General Quantification of Covariate and Concept Shifts
Hongbo Chen, Li C Xia
Generalization under distribution shift remains a core challenge in modern machine learning, yet existing learning bound theory is limited to narrow, idealized settings and is non-estimable from samples. In this paper, we bridge the gap between theory and practical applications. We first show that existing definition of concept shift breaks when the source and target supports mismatch. Leveraging entropic optimal transport, we propose a key notion: $\gamma^\ast$-concept shifts, and derive a general error bound unifying covariate and $\gamma^\ast$-concept shifts, which applies to broad loss functions, label spaces, and stochastic labeling. We further develop estimators for these shifts with concentration guarantees, and the DataShifts algorithm, which can quantify distribution shifts and estimate the error bound in most applications - a rigorous and general tool for analyzing learning error under distribution shift.
****

EEmo-Logic: A Unified Dataset and Multi-Stage Framework for Comprehensive Image-Evoked Emotion Assessment
Lancheng Gao, Ziheng Jia, Zixuan Xing, Wei Sun, Huiyu Duan, Guangtao Zhai, Xiongkuo Min
Understanding the multi-dimensional attributes and intensity nuances of image-evoked emotions is pivotal for advancing machine empathy and empowering diverse human-computer interaction applications. However, existing models are still limited to coarse-grained emotion perception or deficient reasoning capabilities. To bridge this gap, we introduce **EEmoDB**, the largest image-evoked emotion understanding dataset to date. It features 5 analysis dimensions spanning 5 distinct task categories, facilitating comprehensive interpretation. Specifically, we compile $1.2M$ question-answering (QA) pairs (EEmoDB-QA) from $125K$ images via automated generation, alongside a $36K$ dataset (EEmoDB-Assess) curated from $25K$ images for fine-grained assessment. Furthermore, we propose **EEmo-Logic**, an **all-in-one** multimodal large language model (MLLM) developed via instruction fine-tuning and task-customized group relative preference optimization (GRPO) with novel reward design. Extensive experiments demonstrate that EEmo-Logic achieves robust performance in in-domain and cross-domain datasets, excelling in emotion QA and fine-grained assessment.
The dataset and code are available at https://github.com/workerred/EEmo-Logic.

Dive into the Scene: Breaking the Perceptual Bottleneck in Vision-Language Decision Making via Focus Plan Generation
Boyuan Xiao, Bohong Chen, Yumeng Li, Ji Feng, Yao-Xiang Ding, Kun Zhou
In embodied vision-language decision making tasks such as robotic manipulation and navigation, Vision-Language and Vision-Language-Action Models (VLMs \& VLAs) are powerful tools with different benefits: VLMs are better at long-term planning, while VLAs are better at reactive control. However, their performance is limited by the same perceptual bottleneck: visual hallucinations arise due to the models' inability to distinguish task-relevant objects from distractors. In principle, accurate identification and focus on critical objects while filtering out irrelevant ones is the key to break this limitation. A straightforward solution is one-step focus: directly attending to essential objects. However, this approach proves ineffective because effective focus inherently requires deep scene understanding. To this end, we propose ${\it SceneDiver}$, a coarse-to-fine focus plan generation method for VLMs leveraging their long-term planning abilities, that first constructs a holistic scene graph to establish initial comprehension, then progressively decomposes the task into simpler sub-problems through an iterative cycle of recognition, understanding, and analysis. To enable reactive control, we also design a lightweight adapter for distilling the deliberate focus ability into VLAs. Evaluations on standard embodied AI benchmarks confirm that our method substantially reduces visual hallucinations for both VLMs and VLAs, while

preserving computational efficiency in tasks requiring fast execution. Our code and data are released at: https://future-item.github.io/SceneDiver.

Structure Abstraction and Generalization in a Hippocampal-Entorhinal Inspired World Model
Tianqiu Zhang, Muyang Lyu, Xiao Liu, Si Wu
Humans abstract experiences into structured representations to facilitate pattern inference and knowledge transfer. While the hippocampal-entorhinal (HPC-MEC) circuit is known to represent both spatial and conceptual spaces, the mechanisms for concurrently extracting abstract structures from continuous, high-dimensional dynamics remain poorly understood. We propose a brain-inspired hierarchical model that simultaneously infers latent transitions and constructs a predictive visual world model. Our architecture employs an inverse model for structural extraction alongside an HPC-MEC coupling model that dissociates relational structures (MEC) from integrated episodic scenes (HPC). Using rotation dynamics as a benchmark, we demonstrate the model's capacity for structural abstraction. By leveraging velocity-driven path integration, the framework enables robust prediction and structural reuse across diverse contexts, thereby achieving structural generalization. This work provides a novel computational framework for understanding how brain-inspired, self-supervised learning of world models facilitates the acquisition of reusable abstract knowledge.
****
Bridging Dynamics and Data: A Unified Diffusion Framework for Mechanistically-Informed Epidemic Forecasting
Guanghui Min, Tianhao Huang, Ke Wan, Qi R. Wang, Chen Chen
Reliable epidemic forecasting is critical for public health decision-making yet remains challenging due to data sparsity and the non-stationary nature of disease dynamics. While recent hybrid models attempt to integrate mechanistic principles with data-driven approaches, they often relegate mechanistic priors to merely auxiliary features or regularization terms. This design not only obscures the interpretability of the mechanistic contribution but also fails to inherit the capability of physical models to generalize under non-stationary dynamics, as the core architecture remains predominantly data-driven. To address these limitations, we propose EpiDiff, a unified framework that synergizes epidemiological domain knowledge with the generative power of diffusion models. Unlike methods that rigidly fuse features, EpiDiff employs a novel uncertainty-aware steering mechanism during inference. Specifically, we quantify the posterior uncertainty of mechanistic estimations and use it to dynamically modulate the diffusion process. Extensive experiments on real-world datasets demonstrate that EpiDiff consistently outperforms state-of-the-art baselines in accuracy and robustness, particularly under non-stationary distributions, while offering transparent insights into model reliance by explicitly visualizing when the forecast is governed by mechanistic laws versus data-driven patterns.
****
UGround: Towards Unified Visual Grounding with Unrolled Transformers
Rui Qian, Xin Yin, Chuanhang Deng, Zhiyuan Peng, Jian Xiong, Wei Zhai, Dejing Dou
We present UGround, a **U**nified visual **Ground**ing paradigm that dynamically selects intermediate layers across **U**nrolled transformers as "mask as prompt,'' diverging from the prevailing pipeline that leverages the fixed last hidden layer as "$\langle\texttt{SEG}\rangle$ as prompt.'' UGround addresses two primary challenges posed by the prevailing paradigm: (1) its reliance on the fixed last hidden layer, which sequentially amplifies cumulative errors arising from layer-by-layer propagation without intermediate correction, and (2) its use of $\langle\texttt{SEG}\rangle$ as a prompt, which implicitly projects textual embeddings into visual space without explicit spatial cues (e.g., coordinates). Central to UGround is Policy-Prompted Masking, which comprises two key components: Stochastic Skip Connection (SSC) and Mask as Prompt (MasP). SSC is a reinforcement learning policy that, via stochastic sampling, allows each $\langle\texttt{SEG}\rangle$ token to slide across unrolled transformer layers, enabling dynamic layer s

election at which it connects to the vision model (e.g., SAM) in a skip-connecti on fashion. Given the selected hidden layer, MasP uses the similarity map derive d from the $\langle\texttt{SEG}\rangle$ token and image tokens as a soft logit m ask to prompt SAM for mask generation, offering explicit spatial cues through it s activation regions. To validate the effectiveness of UGround, we, for the firs t time, have unified visual grounding within a single framework from an attribut e perspective, spanning from traditional refer expression segmentation to newly proposed reasoning segmentation, single-target to multi-target, positive query t o false premise (empty target). All codes are provided in the supplementary mate rial.

UHR-BAT: Budget-Aware Token Compression Vision-Language model for Ultra-High-Res olution Remote Sensing
Yunkai Dang, Minxin Dai, Yuekun Yang, Zhangnan Li, Wenbin Li, Feng Miao, Yang Ga o
Ultra-high-resolution (UHR) remote sensing imagery couples kilometer-scale conte xt with query-critical evidence that may occupy only a few pixels.
Such vast spatial scale leads to a quadratic explosion of visual tokens and hind ers the extraction of information from small objects.
Previous works utilize direct downsampling, dense tiling, or global top■K prunin g, which either compromise query-critical image details or incur unpredictable c ompute.
In this paper, we propose UHR-BAT, a query-guided and region-faithful token comp ression framework to efficiently select visual tokens under strict context budge t.
Specifically, we leverage text-guided, multi-scale importance estimation for vis ual tokens, effectively tackling the challenge of achieving precise yet low-cost feature extraction.
Furthermore, by introducing region-wise preserve and merge strategies, we mitiga te visual token redundancy, further driving down the computational budget.
The experimental results show that UHR-BAT achieves state-of-the-art performance across various benchmarks.

Efficient Synthetic Network Generation via Latent Embedding Reconstruction
Feifan Jiang, Yinan Bu, Shihao Wu, Gongjun Xu, Ji Zhu
Network data are ubiquitous across the social sciences, biology, and information systems. Generating realistic synthetic network data has broad applications fro m network simulation to scientific discovery. However, many existing black-box a pproaches for network generation tend to overfit observed data while overlooking characteristic network structure, and incur substantial computational overhead at scale. These practical challenges call for synthetic network generation metho ds that are both efficient and capable of capturing structural properties of net works. In this paper, we introduce Synthetic Network Generation via Latent Embed ding Reconstruction (SyNGLER), a general and efficient framework for synthetic n etwork generation that builds on latent space network models. Given an observed network, SyNGLER first learns low-dimensional latent node embeddings via a laten t space network model and then reconstructs the latent space by building a distr ibution-free generator over these embeddings. For generation, SyNGLER first samp les (or resamples) node embeddings from the generator in the latent space and th en produces synthetic networks using the latent space network model. Through the latent space framework, SyNGLER preserves unique characteristics in networks su ch as sparsity and node degree heterogeneity, while allowing for efficient train ing with lower computational cost than many existing deep architectures.
We provide theoretical guarantees by developing consistency results on the dista nce between the true and synthetic edge distributions. Empirical studies further demonstrate the effectiveness of SyNGLER, which efficiently produces networks t hat better preserve key network characteristics such as network moments and degr ee distributions compared with existing approaches. Code is available at https:/ /github.com/FeifanJiang/syngler.

Respecting Modality Gap in Post-hoc Out-of-distribution Detection with Pre-trained Vision-Language Models
Yuanwei Hu, Bo Peng, Yadan Luo, Zhen Fang, Ling Chen, Jie Lu
Out-of-distribution (OOD) detection has emerged as a popular technique to enhance the reliability of machine learning models by identifying unexpected inputs from unknown classes.
Recent progress in pre-trained vision–language models (VLMs) has enabled zero-shot OOD detection without access to in-distribution (ID) training data; in this setting, existing methods commonly treat text embeddings of class names as class prototypes.
In this paper, we challenge this widely adopted “text-as-prototype” paradigm by theoretically showing that off-the-shelf textual prototypes are generally misaligned with the optimal visual prototypes, yielding an intrinsic \textit{modality gap} that cannot be eliminated by prompt engineering alone.
To mitigate this gap under the post-hoc constraint, this paper presents an online pseudo-supervised framework that directly learns class prototypes in the visual feature space using unlabeled test-time data streams and soft predictions from the pre-trained VLMs. We provide theoretical guarantees for the convergence of the online optimization procedure.
Extensive experiments empirically manifest that our method achieves a new state of the art across a variety of OOD detection setups.
****
Unifying Masked Diffusion Models with Various Generation Orders and Beyond
Chunsan Hong, Sanghyun Lee, Jong Chul Ye
Masked diffusion models (MDMs) are a potential alternative to autoregressive models (ARMs) for language generation, but generation quality depends critically on the generation order. Prior work either hard-codes an ordering (e.g., blockwise left-to-right) or learns an ordering policy for a pretrained MDM, which incurs extra cost and can yield suboptimal solutions due to the two-stage optimization. Motivated by this, we propose order-expressive masked diffusion model (OeMDM) for a broad class of diffusion generative processes with various generation orders, enabling the interpretation of MDM, ARM, and block diffusion in a single framework. Furthermore, building on OeMDM, we introduce learnable-order masked diffusion model (LoMDM), which jointly learns the generation ordering and diffusion backbone through a single objective from scratch, enabling the diffusion model to generate text in context-dependent ordering. Empirically, we confirm that LoMDM outperforms various discrete diffusion models across multiple language modeling benchmarks.
****
Beyond Unidirectional Bias: Reciprocal Perspective Calibration in Scene Graph Generation
Haifeng Zhao, Wenbo Zhao, Xuemei Luo, Lei-Lei Ma, Dengdi Sun
Scene Graph Generation (SGG) paradigms predominantly model relationships as static, unidirectional mappings ($s \to o$), effectively treating objects as passive recipients of actions. This formulation suffers from an inherent \textit{unidirectional bias}, violating the physical reality that visual interactions are intrinsically reciprocal. Consequently, existing models often fail to maintain logical self-consistency when the reasoning anchor shifts from the subject to the object. To rectify this cognitive deficiency, we establish the Mutual-Perspective Inverse Relations (MPIR) principle, positing that a robust visual representation must satisfy logical consistency across dual perspectives. Guided by this principle, we propose the \textbf{Reciprocal Perspective Calibration (RPC)} framework, a model-agnostic framework that operationalizes MPIR via a novel Adaptive Inverse-Relation Augmentation (AIRA) strategy. Furthermore, we introduce Hypernym-Guided Prompts (HGP) to bridge the gap between semantic context and computational efficiency in vision-language models, enabling precise modeling of inverse relations. Extensive experiments demonstrate that RPC not only achieves competitive performance on standard benchmarks but also significantly enhances the model's capability to understand inverse relations, as verified by a new inverse consistency evaluation protocol, demonstrating the cognitive robustness of our method.

From Retrieval to Translation: Translating Query into Graph-level Clues for Retrieval-Augmented Generation
Qichuan Liu, Qinggang Zhang, Yuxuan Hu, Chenfeng Zheng, Zerui Chen, Chentao Zhang, Zhihong Zhang
Retrieval-Augmented Generation (RAG) has recently been enhanced with tree or graph structures to match user intent for precise passage retrieval, which facilitates large language models (LLMs) in effectively mitigating hallucinations by leveraging external knowledge. However, we identify that existing structure-augmented RAG systems are experiencing (i) potential retrieval suspension and (ii) cumulative semantic drift, due to low-quality structures and semantic embeddings that often poorly capture textual details. Motivated by this, we propose a novel paradigm named KG-Translator, which is distinct from traditional matching-based paradigms and instead translates user queries into graph-level clues. Specifically, KG-Translator utilizes lightweight models to conduct named entity recognition (NER) and syntactic parsing on the corpus, constructing a reliable knowledge graph (ParseKG). On top of ParseKG, KG-Translator adopts constrained decoding strategies to faithfully translate clues, traces them to original passages, and employs a lightweight ranking model for precise passage retrieval. Extensive experiments on five datasets demonstrate that KG-Translator significantly outperforms baselines.

Context-level Language Modeling by Learning Predictive Context Embeddings
beiya dai, Yuliang Liu, Yunchong Song, Daozheng Xue, Qipeng Guo, Kai Chen, Xinbing Wang, Bowen Zhou, Zhouhan Lin
We propose ContextLM, a framework that implicitly learns multi-token prediction by augmenting standard pretraining with an intrinsic next-context prediction objective. ContextLM builds a language model on top of context embeddings that span multiple tokens, enabling better next-token prediction by predicting the next context. Our model is fully compatible with standard autoregressive, token-by-token evaluation paradigms (e.g., perplexity). Extensive experiments with GPT-2 and Pythia backbones (up to 1.5B parameters and 300B training tokens) reveal that ContextLM shifts the Pareto frontier of scaling laws, exhibiting superior efficiency in parameters, training tokens, and FLOPs. Our results show that ContextLM could already achieve the baseline perplexity using 39\% fewer parameters and demonstrates robust generalization improvements on extensive downstream tasks under equivalent parameter counts.
****
Compositional Generalization Requires Linear, Orthogonal Representations in Vision Embedding Models
Arnas Uselis, Andrea Dittadi, Seong Joon Oh
Compositional generalization, the ability to recognize familiar parts in novel contexts, is a defining property of intelligent systems, yet modern models, despite massive training sets, see only a tiny fraction of the combinatorial input space. We ask what structure representations {must} have to support generalization to unseen combinations. We formalize three desiderata (divisibility, transferability, stability) and show they impose necessary geometric constraints under standard training: representations must decompose linearly into per-concept components, orthogonal across concepts. This grounds the Linear Representation Hypothesis as a necessary consequence of compositional generalization, and yields dimension bounds linking the number of composable concepts to embedding geometry. Empirically, across CLIP, SigLIP, and DINO, we find partial linear factorization with low-rank near-orthogonal per-concept factors, and the degree of this structure correlates with compositional generalization on unseen combinations. As models continue to scale, these conditions predict the geometry they may converge to. Code: https://github.com/oshapio/necessary-compositionality

Not All Answers Are Contextually Persuadable: Inference Dynamics in Large Language Models under Contextual Influence
Zongye Hu, Weiqing Luo, Yanjie Fu, Yu Gan, Haofeng Zhang, Ziyi Huang

At the core of modern prompting techniques is contextual sensitivity, the abilit y of large language models to adapt their predictions based on inference-time co ntext. Despite its central role, inference behavior under strong contextual infl uence remains poorly understood, particularly at the level of internal inference dynamics. To bridge this gap, we introduce a theoretical framework for analyzin g contextual influence through inference dynamics, enabling quantitative charact erization of inference behavior beyond output-level answer changes. Our analysis shows that inference dynamics do not exhibit unbounded drift under repeated con textual assertions. Instead, predictive representations converge to stable, quer y-dependent regimes that fundamentally constrain whether contextual signals can alter a model’s prediction. This leads to a surprising finding: Repeated context ual assertions do not act as accumulating evidence during inference and may ther efore fail to alter a model’s prediction even under unbounded repetition, while in other cases a prediction change becomes inevitable. We empirically validate o ur theoretical predictions across diverse models and tasks, demonstrating strong alignment between theory and observed inference behavior. These contributions o ffer a principled pathway toward characterizing the limits of contextual influen ce during inference, and provide practical implications for designing and evalua ting repetition-based prompting methods.

On Robustness and Chain-of-Thought Consistency of RL-Finetuned VLMs

Rosie Zhao, Anshul Shah, Xiaoyu Zhu, Xinke Deng, Zhongyu Jiang, Yang Yang, Joerg Liebelt, Arnab Kumar Mondal

Reinforcement learning (RL) fine-tuning has become a key technique for enhancing large language models (LLMs) on reasoning-intensive tasks, motivating its exten sion to vision language models (VLMs). While RL-tuned VLMs improve on visual rea soning benchmarks, they remain vulnerable to weak visual grounding, hallucinatio ns, and over-reliance on textual cues. We show that simple, controlled textual p erturbations—misleading captions or incorrect chain-of-thought (CoT) traces—caus e substantial drops in robustness, and that these effects are more pronounced wh en CoT consistency is taken into account across open-source multimodal reasoning models. In contrast, closed models exhibit similar failure modes but maintain m arkedly greater robustness and reasoning consistency, suggesting that the gap re flects a shortcoming in current RL fine-tuning methods rather than an inherent l imitation of the task. To better understand these vulnerabilities, we further a nalyze RL fine-tuning dynamics and uncover an accuracy–faithfulness trade-off: f ine-tuning raises benchmark accuracy, but can simultaneously erode the reliabili ty of the accompanying CoT and its robustness to contextual shifts.

Although adversarial augmentation improves robustness, it does not by itself pre vent faithfulness drift. Incorporating a faithfulness-aware reward can restore a lignment between answers and reasoning, but when paired with augmentation, train ing risks collapsing onto shortcut strategies. Together, these findings highligh t the limitations of accuracy-only evaluations and motivate training and assessm ent protocols that jointly emphasize correctness, robustness, and consistency in visually grounded reasoning.

Demystifying LLM-as-a-Judge: Analytically Tractable Model for Inference-Time Sca ling

Indranil Halder, Cengiz Pehlevan

Recent developments in large language models have shown advantages in reallocati ng a notable share of computational resource from training time to inference tim e. However, the principles behind inference time scaling are not well understood . In this paper, we introduce an analytically tractable model of inference-time scaling: Bayesian linear regression with a reward-weighted sampler, where the re ward is determined from a linear model, modeling LLM-as-a-judge scenario. We stu dy this problem in the high-dimensional regime, where the deterministic equivale nts dictate a closed-form expression for the posterior predictive mean and varia nce. We analyze the generalization error when training data are sampled from a t eacher model. We draw k inference-time samples and select via softmax at a tem perature applied to a quadratic reward. When the reward is not too different fro

m the teacher, the generalization error decreases monotonically with increasing inference time samples k. However, the specific reward that optimizes inferenc e-time selection generally differs from the teacher. In contrast, substantial re ward misspecification induces a finite optimal k beyond which more sampling ca n increase the generalization error. For fixed k, there exists an optimal samp ling temperature. We experimentally verify these facts in large language model i nference with an additional large language model as a judge. In the ``best-of-$k $" limit with the teacher as reward, we theoretically show that the generalizati on error decays as $\Theta(1/k^2)$ and determine the leading coefficient via ext reme value theory. These formulas delineate domains where scaling inference-time computation is provably preferable to collecting more data. Finally, we demonst rate that when task difficulty increases, the previously mentioned advantage of inference-time compute degrades.

GeoDM: Geometry-aware Distribution Matching for Dataset Distillation

Xuhui Li, Zhengquan Luo, Zihui Cui, Kai Zhao, zhiqiang xu

Dataset distillation aims to synthesize a compact subset of the original data, e nabling models trained on it to achieve performance comparable to those trained on the original large dataset. Existing distribution-matching methods are confin ed to Euclidean spaces, making them only capture linear structures and overlook the intrinsic geometry of real data, e.g., curvature.

However, high-dimensional data often lie on low-dimensional manifolds, suggestin g that dataset distillation should have the distilled data manifold aligned with the original data manifold.

In this work, we propose a geometry-aware distribution-matching framework, calle d GeoDM, which operates in the Cartesian product of Euclidean, hyperbolic, and s pherical manifolds, with flat, hierarchical, and cyclical structures all capture d by a unified representation.

To adapt to the underlying data geometry, we introduce learnable curvature and w eight parameters for three kinds of geometries. At the same time, we design an o ptimal transport loss to enhance the distribution fidelity.

Our theoretical analysis shows that the geometry-aware distribution matching in a product space yields a smaller generalization error bound than the Euclidean c ounterparts. Extensive experiments conducted on standard benchmarks demonstrate that our algorithm outperforms state-of-the-art data distillation methods and re mains effective across various distribution-matching strategies for the single g eometries.

Weight-Space Learning for Certifiable Few-shot Transfer Learning

Fady Rezk, Royson Lee, Henry Gouk, Timothy Hospedales, Minyoung Kim

In contemporary deep learning, a prevalent and effective workflow for solving lo w-data problems is adapting powerful pre-trained foundation models (FMs) to new tasks via parameter-efficient fine-tuning (PEFT). However, while empirically eff ective, the resulting solutions lack generalisation guarantees to certify their accuracy - which may be required for ethical or legal reasons prior to deploymen t in high-importance applications. In this paper we develop a novel transfer lea rning approach that is designed to facilitate non-vacuous learning theoretic gen eralisation guarantees for downstream tasks, even in the low-shot regime. Specif ically, we first use upstream tasks to train a {\em distribution over PEFT param eters}. We then learn the downstream task by a {\em sample-and-evaluate} procedu re -- sampling plausible PEFTs from the trained diffusion model and selecting th e one with the highest likelihood on the downstream data. Crucially, this confin es our model hypothesis to a {\em finite} set of PEFT samples. In contrast to th e typical continuous hypothesis spaces of neural network weights, this facilitat es tighter risk certificates. We instantiate our bound and show non-trivial gene ralization guarantees compared to existing learning approaches which lead to vac uous bounds in the low-shot regime.

IACW: Intent-Aware Controllable Watermarking for Scalable Authorial Intent Attri bution

Hao Huang, Ruihua Zhou, JiaTang Luo, Yunpeng Li, Yuling Liu
As Large Language Models (LLMs) integrate into writing workflows, precise govern ance requires distinguishing ''how AI participated'' rather than merely ''whethe r AI was used.'' Traditional binary detection often misclassifies ``AI-polished' ' content as generated, creating fairness risks. We propose shifting from passiv e post-hoc detection to active intent attribution, focusing on the distinction b etween Editing (source-anchored) and Generation (unanchored). We introduce \text bf{IACW-Instruct}, a corpus of diverse editing operations constructed via a Dire ctor--Actor--Judge pipeline to enable systematic evaluation. Building on this be nchmark, we propose \textbf{Intent-Aware Controllable Watermarking (IACW)}, feat uring intent-adaptive entropy gating for semantically lossless embedding. Experi ments show that IACW achieves 95\% attribution accuracy under 20\% token deletio n while preserving near-unwatermarked semantic fidelity, establishing a practica l paradigm for fine-grained provenance.

Small Agent Group is the Future of Digital Health
Yuqiao Meng, Luoxi Tang, Dazheng Zhang, Rafael Brens, Elvys J. Romero, Nancy Guo , Safa elkefi, Zhaohan Xi
The rapid adoption of large language models (LLMs) in digital health has been dr iven by a "scaling-first" philosophy, i.e., the assumption that clinical intelli gence increases with model size and data. However, real-world clinical needs inc lude not only effectiveness, but also reliability and reasonable deployment cost . Since clinical decision-making is inherently collaborative, we challenge the m onolithic scaling paradigm and ask whether a Small Agent Group (SAG) can support better clinical reasoning. SAG shifts from single-model intelligence to collect ive expertise by distributing reasoning, evidence-based analysis, and critical a udit through a collaborative deliberation process. To assess the clinical utilit y of SAG, we conduct extensive evaluations using diverse clinical metrics spanni ng effectiveness, reliability, and deployment cost. Our results show that SAG ac hieves superior performance compared to a single giant model, both with and with out additional optimization or retrieval-augmented generation. These findings su ggest that the synergistic reasoning represented by SAG can substitute for model parameter growth in clinical settings. Overall, SAG offers a scalable solution to digital health that better balances effectiveness, reliability, and deploymen t efficiency.

When Do Diffusion Models Learn to Generate Multiple Objects?
Yujin Jeong, Arnas Uselis, Iro Laina, Seong Joon Oh, Anna Rohrbach
Text-to-image diffusion models achieve impressive visual fidelity, yet they rema in unreliable in multi-object generation.
Despite extensive empirical evidence of these failures, the underlying causes re main unclear.
We begin by asking how much of this limitation arises from the data itself.
To disentangle data effects, we consider two regimes across different dataset si zes:
(1) concept generalization, where each individual concept is observed during tra ining under potentially imbalanced data distributions, and
(2) compositional generalization, where specific combinations of concepts are sy stematically held out.
To study these regimes, we introduce mosaic (Multi-Object Spatial relations, At trIbution, Counting), a controlled framework for dataset generation.
By training diffusion models on mosaic, we find that scene complexity plays a do minant role rather than concept imbalance, and that counting is uniquely difficu lt to learn in low-data regimes.
Moreover, compositional generalization collapses as more concept combinations ar e held out during training.
These findings highlight fundamental limitations of diffusion models and motivat e stronger inductive biases and data design for robust multi-object compositiona l generation.

Message Tuning Outshines Graph Prompt Tuning: A Prismatic Space Perspective
Yancheng Chen, Dun Ma, Shuai Zhang, Yang Liu, Xixun Lin, Xiangyu Zhao, Wenguo Yang, Wei Chen, Chuan Zhou
Graph Foundation Models (GFMs), built upon the *Pre-training and Adaptation* paradigm, have emerged as a research hotspot in graph learning. For GNN-based GFMs, graph prompt tuning has become the prevailing adaptation method for downstream tasks. Although recent methods explain why graph prompt tuning works, how to rigorously measure its adaptation capacity remains an open problem. Addressing this problem is critical for understanding the capability limits of graph prompt tuning and for developing more powerful adaptation methods. In this paper, we propose Prismatic Space Theory (PS-Theory), a novel mathematical framework to quantify the capacity of adaptation methods, while focusing on establishing the upper bound for the adaptation capacity of graph prompt tuning. Building upon the proposed PS-Theory, we further introduce **M**essage **T**uning for **G**FMs (MTG), a lightweight approach that injects a small set of learnable message prototypes into each layer of the GNN backbone to adaptively guide message fusion without updating pre-trained weights. Through our PS-Theory, we prove that the adaptation capacity of MTG can exceed the theoretical upper bound of graph prompt tuning. Extensive experiments demonstrate that MTG consistently outperforms graph prompt baselines across diverse benchmark datasets, providing strong empirical support for our theoretical findings.

Reflect-then-Correct: Rebalancing Task Optimization for Generalizable Meta-Reinforcement Learning via Distributional Value Error Reduction
Min Wang, Xin Li, Ye He, Mingzhong Wang, Yonggang Zhang
Meta-Reinforcement Learning (Meta-RL) faces significant challenges in non-parametric settings, where vastly different return scales across diverse tasks cause severe gradient interference. Existing categorical solutions attempt to normalize these scales but often fail due to rigid discretization and quantization errors. To address this, we propose Reflect-then-Correct (RTC), a framework that models meta-values using Sinkhorn divergence. By treating distributions as adaptive floating particles, RTC achieves a geometry-aware alignment of distinct meta-task structures. However, while Sinkhorn updates harmonize gradients, they introduce statistical bias via sampling estimation. RTC overcomes this issue by "reflecting'' on the temporal accumulation of Bellman inconsistencies through a recursive error model and "correcting'' the optimization via adaptive importance weights, which prioritize more accurate transitions for meta-value estimation. We provide theoretical guarantees for this reweighting strategy and demonstrate that RTC outperforms existing baselines on the challenging Meta-World ML-10 and ML-45 benchmarks.

Deep Pre-Alignment for VLMs
Tianyu Yu, Kechen Fang, Zihao Wan, Kaidong Zhang, Yicheng Zhang, Jun Song, Bo Zheng, Yuan Yao
Most Vision Language Models (VLMs) directly map outputs from ViT encoders to the LLM via a lightweight projector. While effective, recent analysis suggests this architecture suffers from an alignment challenge: visual features remain distant from the text space in the initial layers of the LLM, forcing the model to waste critical depth on superficial modality alignment rather than deep understanding and complex reasoning. In this work, we propose Deep Pre-Alignment (DPA), a novel architecture that replaces the standard ViT encoder with a small VLM as perceiver, ensuring visual features are deeply aligned with the text space of the target large language model.
Comprehensive experiments demonstrate the effectiveness of DPA. On the 4B parameter scale, DPA outperforms baselines by 1.9 points across 8 multimodal benchmarks, with gains widening to 3.0 points at the 32B scale. Moreover, by offloading alignment to the perceiver, DPA achieves a 32.9\% reduction in language capability forgetting over 3 text benchmarks. We further demonstrate that these gains are consistent across different LLM families including Qwen3 and LLaMA 3.2, highlighting the generality of our approach.

Beyond performance, DPA also offers a seamless upgrade path for current VLM deve
lopment, requiring only a modular replacement for the visual encoder with margin
al computation overhead.

Multi-Objective Preference Optimization: Improving Human Alignment of Generative
 Models

Akhil Agnihotri, Rahul Jain, Deepak Ramachandran, Zheng Wen

Post-training LLMs with RLHF and preference optimization methods (e.g., DPO, IPO
) has greatly improved alignment, yet these approaches assume a single objective
. In reality, humans express multiple, often conflicting objectives, such as hel
pfulness and harmlessness, with no natural scalarization. We study the multi-obj
ective preference alignment problem, where a policy must balance several objecti
ves simultaneously. We propose Multi-Objective Preference Optimization (MOPO), a
 constrained KL-regularized framework that maximizes a primary objective while e
nforcing lower bounds on secondary objectives via tunable safety thresholds. MOP
O operates directly on pairwise preferences without point-wise rewards, and admi
ts simple closed-form iterative updates. Empirically, MOPO recovers Pareto-optim
al policies on synthetic benchmarks and, when fine-tuned on human-preference dat
a, yields multi-billion parameter models that achieve higher rewards and Pareto-
dominate baselines, with stable and robust optimization dynamics.

On Testing Conditional Mean Independence for Manifold-Valued Data

Meiling Zeng, Jinhong You, Jicai Liu, Shouxia Wang

This paper introduces a nonparametric test for conditional mean independence bet
ween a manifold■valued Y and Euclidean predictors X. The test is built on a
new measure called the Manifold Martingale Difference Divergence (MMDD), which c
haracterizes conditional mean dependence by projecting observations onto the tan
gent space via the logarithmic map. We provide an empirical estimator for the MM
DD, establish its asymptotic null distribution, and implement a wild bootstrap p
rocedure for finite■sample inference. Simulations on three representative manifo
lds demonstrate that the proposed test maintains correct size under the null eve
n when the distribution of Y depends on X, in contrast to the severe size d
istortion exhibited by the distance covariance (dCov) test. At the same time, it
 achieves competitive power across a range of alternatives. An application to re
al data illustrates its practical utility.

Don't Drop Dropout: Optimizing Layer Sparsity for Efficient LLM Training and Inf
erence

Mostafa Elhoushi, Alexander D. Pretko, Nolan Simran Dey, Bin Claire Zhang, Gavia
 Gray, Gurpreet Gosal, Abdulrahman Mahmoud, Shane Bergsma, Joel Hestness

Layer dropout (a.k.a.\ stochastic depth) has been shown to enable faster trainin
g, higher accuracy, and robustness to zero-shot layer pruning in both language a
nd vision transformers. However, as models and datasets have scaled, dropout---p
articularly layer dropout---has largely disappeared from LLM pre-training recipe
s. While some prior work has reported that dropout can degrade accuracy, no comp
rehensive study has quantified, let alone mitigated, this effect. In this study,
 we show that layer dropout **should** be used in state-of-the-art LLM training,
 establishing best practices and scaling analysis for both training and post-tra
ining benefits. Concretely, with optimal layer distribution, time schedule, and
optimizer hyperparameters, LLM can achieve lower or similar validation loss whil
e saving upto 20\% of training FLOPs. Moreover, layer dropout enables significan
t post-training optimizations, such as early exit, intermediate-layer skipping,
and self-speculative decoding, yielding up to 1.4x inference speedup with neglig
ible accuracy loss.

All pre-training experiments were run on Cerebras CS-3 systems.

Formal Concept Lattices are Good Semantic Scaffolds for Concept-Based Learning

Deepika Vemuri, Sayanta Adhikari, Ankit Saha, Krishn Vishwas Kher, Vineeth N. Ba
lasubramanian

Learning semantics is essential for deep learning models to be interpretable and

better aligned with human reasoning. Concept-based models approach this by representing classes through meaningful semantic abstractions, but typically treat all concepts as a flat, unstructured set learned at a single neural network layer.
This overlooks a fundamental property of human semantic understanding: concepts being organized hierarchically, from general to specific.
While deep networks do learn a hierarchy of visual features, this structure is rarely aligned with explicit semantic hierarchies.
Drawing on Formal Concept Analysis, we demonstrate that formal concept lattices provide principled semantic scaffolds to guide neural network learning. These lattices naturally identify where in the network concepts should be learned based on their level of generality. This allows the model to develop staged, semantically grounded representations throughout its depth.
Empirical results on real-world datasets show that our models produce more interpretable embeddings, support more effective interventions, and learn concept representations that are both meaningful and hierarchically structured.

XRPO: Pushing the Limits of GRPO with Targeted Exploration and Exploitation
Udbhav Bamba, Minghao Fang, Yifan Yu, Haizhong Zheng, Fan Lai
Reinforcement learning algorithms such as GRPO have driven recent advances in large language model (LLM) reasoning. While scaling the number of rollouts stabilizes training, existing approaches suffer from limited exploration on challenging prompts and leave informative feedback signals underexploited, due to context-independent rollout allocation across prompts (e.g., generating 16 rollouts per prompt) and relying heavily on sparse rewards. This paper presents XRPO (eXplore–eXploit GRPO), a unified framework that recasts policy optimization through the principled lens of rollout exploration–exploitation. To enhance exploration, XRPO introduces a mathematically grounded rollout allocator that adaptively prioritizes prompts with higher potential for uncertainty reduction. It further addresses stagnation on zero-reward prompts through an in-context seeding strategy that injects curated exemplars, steering the model into more difficult reasoning trajectories. To strengthen exploitation, XRPO develops a group-relative, novelty-aware advantage sharpening mechanism that leverages sequence likelihoods to amplify low-probability yet correct responses, thereby extending the policy’s reach beyond sparse rewards. Experiments across diverse math and coding benchmarks on both reasoning and non-reasoning models demonstrate that XRPO outperforms existing advances (e.g., GRPO and GSPO) up to 4% pass@1 and 6% cons@32, while accelerating training convergence by up to 2.7x.

On the Infinite Width and Depth Limits of Predictive Coding Networks
Francesco Innocenti, El Mehdi Achour, Rafal Bogacz
Predictive coding (PC) is a biologically plausible alternative to standard backpropagation (BP) that minimises an energy function with respect to network activities before updating weights. Recent work has improved the training stability of deep PC networks (PCNs) by leveraging some BP-inspired reparameterisations. However, the full scalability and theoretical basis of these methods remain unclear. To address this gap, we study the infinite width and depth limits of PCNs. For linear residual networks, we show that the set of width- and depth-stable feature-learning parameterisations for PC is exactly the same as for BP. Moreover, under any of these parameterisations, the PC energy with equilibrated activities converges to the quadratic BP loss when the model width is much larger than the depth, resulting in PC computing the same gradients as BP. Experiments show that, as long as an activity equilibrium is reached, convergence to BP holds for nonlinear models including convolutional networks and transformers. Overall, this work constrains the types of parameterisation that are scalable with PC, while showing a way in which BP can be effectively implemented with only local updates in much wider than deep networks like the brain.

Adaptive Personalized Federated Learning via Multi-task Averaging of Kernel Mean Embeddings

Jean-Baptiste Fermanian, Batiste Le Bars, Aurélien Bellet
Personalized Federated Learning enables a collection of agents to collaboratively learn individual models without sharing raw data. We propose a new approach in which each agent optimizes a weighted combination of all agents' empirical risks, with the weights learned from data rather than specified a priori. The novelty of our method lies in formulating the estimation of these collaborative weights as a kernel mean embedding estimation problem with multiple data sources, leveraging tools from multi-task averaging to capture statistical relationships between agents. This perspective yields a fully adaptive procedure that requires no prior knowledge of data heterogeneity and automatically transitions between global and local learning regimes. By recasting the objective as a high-dimensional mean estimation problem, we derive finite-sample guarantees on local excess risks for a broad class of distributions, explicitly quantifying the statistical gains of collaboration. To address communication constraints inherent to federated settings, we also propose a practical implementation based on random Fourier features, which allows one to trade communication cost for statistical efficiency. Numerical experiments validate our theoretical results.
****

Beyond Sample-Level Forgetting: Improving Reliability in Multimodal Unlearning
Jianzhou Wang, Yirui Wu, Lixin Yuan, Wenxiao Zhang, Jun Liu
Multimodal unlearning aims to eliminate specific data from pretrained multimodal models, which offers significant advantages in data privacy and model efficiency.
Current methods struggle to achieve the desired properties of effectiveness, reliability and locality, due to the complex interdependency of unimodal and multimodal knowledge. By introducing a causal perspective, we propose multimodal unlearning with decoupled knowledge components. To promote fine-grained understanding of multimodal context, we introduce Multimodal Variational Inference (MVI) to infer modal-specific and -consistent factors with incomplete sample observation. With foundation of decoupled knowledge, we propose contrastive semantic editing to regulate multimodal unlearning towards refined forgetting. Experiments on privacy- and copyright-sensitive scenarios validate effectiveness of our method across multiple scenarios, ensuring the unlearned model maintains high reliability and locality.

Calibrated Knowledge Aggregation in Bayesian Mixture-of-Experts for Continual VQA
Mahsa Mozaffari, Hitesh Sapkota, Yu Kong, Xumin Liu, Qi Yu
Continual learning for visual question answering (VQA) is typically implemented by training one expert per task and routing each query using task-ID supervision. Yet continual VQA tasks overlap substantially: on the VQA-v2 task stream, a non-native expert outperforms the task’s own expert on 49.9% of queries, so hard routing both wastes transferable knowledge and can be confidently wrong when mismatched. We propose a calibrated Bayesian mixture-of-experts that trains parameter-efficient per-task adapters, learns routing by directly maximizing expected VQA utility, and marginalizes expert identity at inference via Bayesian aggregation in a unified answer space; an entropy penalty prevents the utility objective from collapsing to one-hot routing, enabling evidence pooling across plausible experts. We reach 64.16 accuracy with 0.63 forgetting on VQA-v2 CL-LS ($+5.74\%$ accuracy, -2.99 forgetting vs. the strongest prior method), 78.81 with 0.40 forgetting on TDIUC CL-LS ($+3.10$, -1.74), and 83.41 with 3.21 forgetting on TDIUC CL-VS ($+1.58$, -0.82). Calibration also improves on VQA-v2, reducing ECE from 0.15 to 0.07.
****

RDT2: Exploring the Scaling Limit of UMI Data Towards Zero-Shot Cross-Embodiment Generalization
Songming Liu, Bangguo Li, Kai Ma, Lingxuan Wu, Hengkai Tan, Xiao Ouyang, Hang Su, Jun Zhu
Vision-Language-Action (VLA) models hold promise for generalist robotics but currently struggle with data scarcity, architectural inefficiencies, and the inabil

ity to generalize across different hardware platforms. We introduce RDT2, a robotic foundation model built upon a 7B parameter VLM designed to enable zero-shot deployment on novel embodiments for open-vocabulary tasks. To achieve this, we collected one of the largest open-source robotic datasets—over $10,000$ hours of demonstrations in diverse families—using an enhanced, embodiment-agnostic Universal Manipulation Interface (UMI). Our approach employs a novel three-stage training recipe that aligns discrete linguistic knowledge with continuous control via Residual Vector Quantization (RVQ), flow-matching, and distillation for real-time inference. Consequently, RDT2 becomes one of the first models that simultaneously zero-shot generalizes to unseen objects, scenes, instructions, and even robotic platforms. Besides, it outperforms state-of-the-art baselines in dexterous, long-horizon, and dynamic downstream tasks like playing table tennis.
****

When Single Answer Is Not Enough: Rethinking Single-Step Retrosynthesis Benchmarks for LLMs
Bogdan Zagribelnyy, Ivan Ilin, Maksim Kuznetsov, Nikita Bondarev, Roman Schutski, Thomas MacDougall, Rim Shayakhmetov, Zulfat Miftahutdinov, Mikolaj Mizera, Vladimir Aladinskiy, Alex Aliper, Alex Zhavoronkov
Recent progress has expanded the use of large language models (LLMs) in drug discovery, including synthesis planning. However, objective evaluation of retrosynthesis performance remains limited. Existing benchmarks and metrics typically rely on published synthetic procedures and Top-K accuracy based on single ground-truth, which does not capture the open-ended nature of real-world synthesis planning. We propose a new benchmarking framework for single-step retrosynthesis that evaluates both general-purpose and chemistry-specialized LLMs using ChemCensor, a novel metric for chemical plausibility. By emphasizing plausibility over exact match, this approach better aligns with human synthesis planning practices. We also introduce CREED, a novel dataset comprising millions of ChemCensor-validated reaction records for LLM training, and use it to train a model that improves over the LLM baselines under this benchmark.
****

Align Your Trajectory Tangent: Training Better Consistency Models via Manifold-Aligned Tangents
Beomsu Kim, ByungHee Cha, Jong Chul Ye
With diffusion and flow matching models achieving state-of-the-art generating performance, the interest of the community now turned to reducing the inference time without sacrificing sample quality.
Consistency Models (CMs), which are trained to be consistent on diffusion or probability flow ordinary differential equation (PF-ODE) trajectories, enable one or two-step flow or diffusion sampling.
However, CMs typically require prolonged training with large batch sizes to obtain competitive sample quality.
In this paper, we examine the training dynamics of CMs near convergence and discover that CM trajectory tangents -- CM output update directions -- are quite oscillatory, in the sense that they move parallel to the data manifold, not towards the manifold.
To mitigate oscillatory trajectory tangents, we propose a new loss function, called the {\em manifold feature distance (MFD)}, which provides manifold-aligned trajectory tangents that point toward the data manifold.
Consequently, our method -- dubbed {\em Align Your Trajectory Tangent (AYT)} -- can accelerate CM training by orders of magnitude and even out-perform the learned perceptual image patch similarity metric (LPIPS).
Furthermore, we find that our loss enables training with extremely small batch sizes without compromising sample quality.
Code is available at \url{https://github.com/1202kbs/AYT}

IdEst: Assessing Self-Supervised Learning Representations via Intrinsic Dimension
Julie Mordacq, Vicky Kalogeiton, Steve Oudot
Self-supervised learning (SSL) has emerged as a powerful paradigm for

learning meaningful representations from unlabeled data.
However, the standard protocol for evaluating these representations,
linear probing,
is computationally expensive,
sensitive to hyperparameters, and provides limited insight
into the geometric structure of the representation space.
In this work, motivated by connections between neural network generalization
and intrinsic dimension (ID) we propose IdEst,
a method for estimating the ID of SSL representations
via the Minimum Spanning Tree dimension estimator ($\mathrm{dim}_\mathrm{MST}$).
Across diverse datasets, architectures, and SSL pretraining objectives,
we show that IdEst strongly correlates with downstream linear probe
performances.
Furthermore, we demonstrate that IdEst enables efficient hyperparameter selectio
n,
significantly reducing the computational cost compared to supervised
alternatives.
Our results highlight intrinsic dimensionality
as a principled geometric proxy for assessing SSL representations,
complementing standard supervised probing protocols.

PhysHanDI: Physics-Based Reconstruction of Hand-Deformable Object Interactions
Jihyun Lee, Changmin Lee, Donghwan Kim, Tae-Kyun Kim
While existing methods for reconstructing hand–object interactions have made imp
ressive progress, they either focus on rigid or part-wise rigid objects—limiting
 their ability to model real-world objects (e.g., cloth, stuffed animals) that e
xhibit highly non-rigid deformations—or model deformable objects without full 3D
 hand reconstruction. To bridge this gap, we present PhysHanDI (Physics-based Re
construction of Hand and Deformable Object Interactions), a framework that enabl
es full 3D reconstruction of both interacting hands and non-rigid objects. Our k
ey idea is to physically simulate object deformations driven by forces induced f
rom densely reconstructed 3D hand motions, ensuring that the reconstructed objec
t dynamics are both physically plausible and coherent with the interacting hand
movements. Furthermore, we demonstrate that such simulation of object deformatio
ns can, in turn, refine and improve hand reconstruction via inverse physics. In
experiments, PhysHanDI outperforms the state-of-the-art baseline across reconstr
uction and future prediction.

Minibatch Optimal Transport and Perplexity Bound Estimation in Discrete Flow Mat
ching
Etrit Haxholli, Yeti Z. Gurbuz, O■ul Can, Eli Waxman
Discrete flow matching, a recent framework for modeling categorical data, has sh
own competitive performance with autoregressive models. However, unlike continuo
us flow matching, the rectification strategy cannot be applied due to the stocha
sticity of discrete paths, necessitating alternative methods to minimize state t
ransitions. We propose a dynamic-optimal-transport-like minimization objective a
nd derive its Kantorovich formulation for discrete flows with convex interpolant
s, where transport cost depends solely on inter-state dissimilarity and can be o
ptimized via minibatch strategies. We show that such methods can reduce the numb
er of transitions up to 32 times (1024 to 32) to reach the same generative perpl
exity without compromising diversity. Additionally, path nondeterminism in discr
ete flows precludes an instantaneous change-of-variables analogue, preventing pr
ecise probability estimation available to continuous flows. We therefore propose
 two upper bounds on perplexity, enabling principled training, evaluation and mo
del comparison. Finally, we introduce Multimask Flows which outperform masked fl
ows in generative perplexity without compromising diversity, particularly when u
tilizing minibatch Optimal Transport.

A Theoretical Framework for Statistical Evaluability of Generative Models
Shashaank Aiyer, Yishay Mansour, Shay Moran, Han Shao

Statistical evaluation aims to estimate the generalization performance of a model using held-out i.i.d. test data sampled from the ground-truth distribution. In supervised learning settings such as classification, performance metrics such as error rate are well-defined, and test error reliably approximates population error given sufficiently large datasets. In contrast, evaluation is more challenging for generative models due to their open-ended nature: it is unclear which metrics are appropriate and whether such metrics can be reliably evaluated from finite samples.

In this work, we introduce a theoretical framework for evaluating language models and establish evaluability results for commonly used metrics. We study two categories of metrics: test-based metrics, including integral probability metrics (IPMs), and similarity-based metrics, including Rényi and KL divergences. We show that IPMs with respect to any bounded test class can be evaluated from finite samples up to multiplicative and additive approximation errors. Moreover, when the test class has finite fat-shattering dimension, IPMs can be evaluated with arbitrary precision. In contrast, similarity-based metrics, including Rényi and KL divergences, are not evaluable from finite samples, as their values can be critically determined by rare events. We also analyze the potential and limitations of perplexity as an evaluation method.
****
L^3: Large Lookup Layers
Albert Tseng, Christopher De Sa
Modern sparse language models typically achieve sparsity through Mixture-of-Experts (MoE) layers, which dynamically route tokens to dense MLP "experts."
However, dynamic hard routing has a number of drawbacks, such as potentially poor hardware efficiency and needing auxiliary losses for stable training.
In contrast, the tokenizer embedding table, which is natively sparse, largely avoids these issues by selecting a single embedding per token at the cost of not having contextual information.
In this work, we introduce the Large Lookup Layer (L3), which generalizes embedding tables to model decoder layers as a means of further scaling sparsity.
L3 layers use static token-based routing to aggregate a *set* of learned embeddings per token in a *context-dependent way*, allowing the model to efficiently balance memory and compute by caching information in embeddings.
L3 has two main components: (1) a systems-friendly architecture that allows for fast training and CPU-offloaded inference with no overhead, and (2) an information-theoretic embedding allocation algorithm that effectively balances speed and quality.
We empirically test L3 by training transformers with up to 2.6B active parameters and find that L3 strongly outperforms both dense models and iso-sparse MoEs in both language modeling and downstream tasks.
****
EchoRL: Reinforcement Learning via Rollout Echoing
Jinhe Bi, Aniri, Minglai Yang, Xingcheng Zhou, Wenke Huang, Sikuan Yan, Yujun Wang, Zixuan Cao, Michael Färber, Xun Xiao, Volker Tresp, Yunpu Ma
Reinforcement Learning with Verifiable Rewards is an effective route for post-training to strengthen the reasoning capability of large language models.
However, as training proceeds, the learning signal can collapse thus makes the training gain become marginal and ineffective.
Specifically, a growing fraction of prompts' rollouts become advantage-degenerated: all the self-generated rollouts show verified-success, making the standard deviation over their rewards be zero; accordingly each rollout's advantage becomes degenerated (zero) as well.
Given such rollouts' advantages, the policy-gradient for model optimization eventually vanishes, capping the training performance.
We argue that some of these rollouts still contain valuable learning signals but unfortunately omitted with the existing RLVR methods.
In this paper, inspired through analyzing the entropy pattern behind golden trajectories produced by external expert models, we propose EchoRL for better exploi

ting the advantage-degenerated rollouts to further improve the training performance.
EchoRL is a lightweight module that first identifies an EchoClip from verified-success rollouts based on their step-level entropy values, and then feeds this clip back as an auxiliary supervision signal in the RL objective.
Extensive experiments across 10 benchmarks, 5 LLM backbones, and 7 popular RLVR post-training methods demonstrate that EchoRL consistently improves RLVR post-training with minimal overhead.

MASPOB: Bandit-Based Prompt Optimization for Multi-Agent Systems with Graph Neural Networks
Zhi Hong, Qian Zhang, Jiahang Sun, Zhiwei Shang, Mingze Kong, Xiangyi Wang, Yao Shu, Zhongxiang Dai
Large Language Models (LLMs) have achieved substantial success in real-world applications, particularly as the cognitive backbone of Multi-Agent Systems (MAS) for orchestrating complex workflows. Since many deployments preclude workflow modifications while MAS performance is highly prompt-sensitive, prompt optimization becomes a critical strategy for improvement. However, real-world prompt optimization for MAS is impeded by three key challenges: (1) the need of sample efficiency due to prohibitive evaluation costs, (2) topology-induced coupling among prompts, and (3) the combinatorial explosion of the search space. To address these challenges, we introduce **MASPOB** (**M**ulti-**A**gent **S**ystem **P**rompt **O**ptimization via **B**andits), a novel sample-efficient framework based on bandits. By leveraging Upper Confidence Bound (UCB) to quantify uncertainty, the bandit framework balances exploration and exploitation, maximizing gains within a strictly limited budget. To handle topology-induced coupling, MASPOB integrates Graph Neural Networks (GNNs) to capture structural priors, learning topology-aware representations of prompt semantics. Furthermore, it employs coordinate ascent to decompose the optimization into univariate sub-problems, reducing search complexity from exponential to linear. Extensive experiments across diverse benchmarks demonstrate that MASPOB achieves state-of-the-art performance, consistently outperforming existing baselines. Our code is available at <https://github.com/HZ1008/MASPOB>.

GemDepth: Geometry-Embedded Features for 3D-Consistent Video Depth
Yuecheng Liu, Junda Cheng, Longliang Liu, Wenjing Liao, Hanrui Cheng, Yuzhou Wang, Xin Yang
Video depth estimation extends monocular prediction into the temporal domain to ensure coherence. However, existing methods often suffer from spatial blurring in fine-detail regions and temporal inconsistencies. We argue that current approaches, which primarily rely on temporal smoothing via Transformers, struggle to maintain strict 3D geometric consistency—particularly under rotations or drastic view changes. To address this, we propose GemDepth, a framework built on the insight that an explicit awareness of camera motion and global 3D structure is a prerequisite for 3D consistency. Distinctively, GemDepth introduces a Geometry-Embedding Module (GEM) that predicts inter-frame camera poses to generate implicit geometric embeddings. This injection of motion priors equips the network with intrinsic 3D perception and alignment capabilities. Guided by these geometric cues, our Alternating Spatio-Temporal Transformer (ASTT) captures latent point-level correspondences to simultaneously enhance spatial precision for sharp details and enforce rigorous temporal consistency. Furthermore, GemDepth employs a data-efficient training strategy, effectively bridging the gap between high efficiency and robust geometric consistency. As shown in Fig.2, comprehensive evaluations demonstrate that GemDepth achieves state-of-the-art performance across multiple datasets, particularly in complex dynamic scenarios.

Towards Understanding Steering Strength
Magamed Taimeskhanov, Samuel Vaiter, Damien Garreau
A popular approach to post-training control of large language models (LLMs) is the steering of intermediate latent representations. Namely, identify a well-chos

en direction depending on the task at hand and perturbs representations along th
is direction at inference time. While many propositions exist to pick this direc
tion, considerably less is understood about how to choose the magnitude of the m
ove, whereas its importance is clear: too little and the intended behavior does
not emerge, too much and the model's performance degrades beyond repair. In this
 work, we propose the first theoretical analysis of steering strength. We charac
terize its effect on next token probability, presence of a concept, and cross-en
tropy, deriving precise qualitative laws governing these quantities. Our analysi
s reveals surprising behaviors, including non-monotonic effects of steering stre
ngth. We validate our theoretical predictions empirically on eleven language mod
els, ranging from a small GPT architecture to modern models.

njing Huang

Reinforcement fine-tuning (RFT) has shown promise for training LLM agents to per
form multi-turn decision-making based on environment feedback. However, most exi
sting evaluations remain largely in-domain—training and testing are conducted in
 the same environment or even on the same tasks. In real-worlddeployment, agent
s may operate in unseen environments with different background knowledge, observ
ation spaces, and action interfaces. To characterize the generalization profile
of RFT under such shifts, we conduct a systematic study along three axes: (1) wi
thin-environment generalization across task difficulty, (2) cross-environment tr
ansfer to unseen environments, and (3) sequential multi-environment training to
quantify transfer and forgetting. Our results show that RFT generalizes well acr
oss task difficulty within an environment, but exhibits unstable transfer to uns
een environments, which correlates with shifts in both semantic priors and obser
vation/action interfaces. In contrast, sequential training yields promising down
stream gains with minimal upstream forgetting, and mixture training across envir
onments improves the overall balance. We further provide detailed analyses and d
eeper insights, and hope our work helps the community develop and deploy general
izable LLM agents.

Batched First-Order Methods for Parallel LP Solving in MIP

Nicolas Blin, Stefano Gualandi, Christopher Maes, Andrea Lodi, Bartolomeo Stella
to

We present a batched first-order method for solving multiple linear programs in
parallel on GPUs. Our approach extends the primal-dual hybrid gradient algorithm
 to efficiently solve batches of related linear programming problems that arise
in mixed-integer programming techniques such as strong branching and bound tight
ening. By leveraging matrix-matrix operations instead of repeated matrix-vector
operations, we obtain significant computational advantages on GPU architectures.
 We demonstrate the effectiveness of our approach on various case studies and id
entify the problem sizes where first-order methods outperform traditional simple
x-based solvers, depending on the computational environment. This is a significa
nt step toward integer programming algorithms that tightly exploit GPU capabilit
ies. We argue that some specific operations should be allocated to GPUs and perf
ormed in full, instead of relying on lightweight heuristic approaches on CPUs.

Provably Label-Efficient Conformal Prediction

Andrew Ilyas, Joonhyuk Ko, Jingwu Tang, Steven Wu, Jiahao Zhang

Conformal prediction converts any black-box predictor into one with finite-sampl
e, distribution-free coverage guarantees, outputting prediction sets $T(x)$ that
 contain the true label with probability at least $1-\alpha$. To construct these
 prediction sets, conformal prediction relies on a randomly sampled ``calibratio
n set'' of labeled examples. In many applications, however, this labeled calibra
tion set is costly to collect, creating a tradeoff between upfront labeling cost
 and downstream utility of the conformal predictor. In this work, we study *conf

ormal prediction with costly label queries*, where unlabeled examples arrive i.i.d. and labels can be queried one at a time. After m queries, we form a conformal predictor; the upfront cost of this predictor is the calibration set size m, and its efficiency is the expected prediction set size $\mathbb{E}|T_m(X)|$. We design an online stopping rule $\hat{m}$ that automatically balances the upfront cost against conformal efficiency *while preserving the original conformal guarantee*. Theoretically, we show that under mild regularity assumptions, the expected total cost of our stopping rule matches the best fixed calibration size in hindsight. Experimentally, we find that our stopping rule reduces cost compared to standard choices of m from the literature by 40.6% $\pm$ 2.3%. Finally, we demonstrate a reduction from the probably approximately correct labeling problem of Candès et al. (2025) to CP, under which our stopping rule minimizes the total labeling cost.

State-Dependent Safety Failures in Multi-Turn Language Model Interaction
Pengcheng Li, Jie Zhang, Tianwei Zhang, Han Qiu, Zhang kejun, Weiming Zhang, Nenghai Yu, Wenbo Zhou
Safety alignment in large language models is typically evaluated under isolated queries, yet real-world use is inherently multi-turn.
Although multi-turn jailbreaks are empirically effective, the structure of conversational safety failure remains insufficiently understood.
In this work, we study safety failures from a state-space perspective and show that many multi-turn safety failures in current safety-aligned language models arise from contextual state evolution, a regime that is not fully captured by isolated prompt-level analyses alone.
We introduce STAR, a state-oriented diagnostic framework that treats dialogue history as a state transition operator and enables controlled analysis of safety behavior along interaction trajectories.
Rather than optimizing attack strength, STAR provides a principled probe of how aligned models traverse the safety boundary under autoregressive conditioning.
Across multiple frontier language models, we find that systems which appear robust under static evaluation can undergo rapid and reproducible safety collapse under structured multi-turn interaction.
Mechanistic analysis reveals monotonic drift away from refusal-related representations and abrupt phase transitions induced by role-conditioned context.
Together, these findings motivate viewing language model safety as a dynamic, state-dependent process defined over conversational trajectories.

Glimpse: Geometry Learning of Multi-scale Structural Priors for 3D Pose Estimation
Zhenhua Tang, Jihua Peng, Yanbin Hao, Qiguang Miao, Chi-Man Pun
Monocular 3D human pose estimation is fundamentally challenged by severe occlusion and inherent depth ambiguity. To address this, we propose Glimpse, a framework that learns robust 3D poses by explicitly modeling anatomical geometry from a single image. We recast the problem as geometry learning of multi-scale structural priors, realized through two synergistic components. First, structured sampling captures the body's geometric continuity through dual-level feature extraction, acquiring both local joint appearance and continuous features along skeletal limbs via deformable sampling. By propagating limb-level geometric cues to their connected joints, this design bridges information gaps caused by occlusion. Second, geometric correction ensures global 3D consistency by lifting coherent 2D features into a canonical 3D reference space, where a shared 3D anchor guides a distance-aware fusion mechanism. Extensive experiments conducted on Human3.6M and MPI-INF-3DHP demonstrate that Glimpse achieves state-of-the-art performance, with superior robustness under severe occlusion and complex articulation.

DDIM Inversion as a Perturbation Amplifier: Breaking Mimicry Protection via Reconstruction Error Minimization
Huming Qiu, Peiyi Chen, Mi Zhang, Geng Hong, Xiaoyu You, Mi Wen, Min Yang
Personalization techniques for image generation models have increasingly been mi

sused for malicious purposes, including unauthorized style imitation and copyrig
hted content replication. In response, recent mimicry protection methods embed c
arefully designed perturbations into images to disrupt a model’s ability to lear
n genuine semantic representations. Despite their growing adoption, the robustne
ss of these protection mechanisms remains poorly understood, raising concerns ab
out their reliability in real-world deployment.
In this work, we present the first systematic analysis showing that DDIM inversi
on inherently acts as a perturbation amplifier, causing protected images to suff
er severe structural distortions during reconstruction. Building on this observa
tion, we propose DDIM Inversion-based Reconstruction Purification (DIRP), a nove
l purification approach that removes protective perturbations by explicitly mini
mizing DDIM inversion reconstruction error under perceptual constraints. Extensi
ve experiments on six existing mimicry protection methods demonstrate that DIRP
consistently outperforms five state-of-the-art attack baselines, achieving super
ior perturbation removal while better preserving image quality. Our results expo
se fundamental vulnerabilities in current mimicry protection strategies and high
light the urgent need for more robust and principled defenses.

CHB: A Diagnostic Toolkit for Hardness-Aware Clustering Evaluation

Walid Durani, Philipp Jahn, Collin Leiber, David B. Hoffmann, Thomas Seidl, Clau
dia Plant, Christian Böhm

Clustering is commonly compared through leaderboards that collapse performance i
nto a single aggregate ranking. Such summaries obscure why methods succeed, whic
h data properties align with failure, and how conclusions shift under representa
tion changes and realistic tuning constraints. We present CHB, a diagnostic tool
kit for hardness-aware clustering evaluation. CHB maps each dataset--representat
ion pair to an interpretable hardness fingerprint capturing (i) separation, (ii)
 cohesion and scale heterogeneity, and (iii) topology through scalable persisten
t-homology summaries. Using this diagnostic space, CHB evaluates clustering algo
rithms under standardized, compute-aware tracks. Conditioning results on hardnes
s coordinates turns comparison into diagnosis: across a broad range of datasets
and their representations, CHB reveals reproducible structural regimes, uncovers
 regime-dependent ranking reversals across method families, and surfaces robustn
ess signatures, including topology-linked breakdowns. CHB further enables repres
entation auditing by attributing gains to measurable shifts in the hardness fing
erprint rather than just external performance changes. We release CHB as an open
, extensible artifact for evaluating new clustering methods and embeddings withi
n a shared diagnostic framework.

BIOARC: Discovering Optimal Neural Architectures for Biological Foundation Model
s

Yi Fang, Haoran Xu, Jiaxin Han, Sirui Ding, Yizhi Wang, Yue Wang, Xuan Wang

Foundation models have revolutionized AI, yet biological applications often repu
rpose general architectures without accounting for the intrinsic structural and
functional properties of distinct modalities, such as genomic and proteomic sequ
ences. Consequently, these architectures lack the inductive biases required to c
apture the complex ``grammars" inherent to biological data, resulting in subopti
mal performance. To address this, we introduce BioArc, a framework utilizing Neu
ral Architecture Search (NAS) to shift from intuition-driven design to automated
 data-driven discovery. Unlike standard NAS restricted to homogeneous spaces, Bi
oArc navigates a heterogeneous space for open-ended composition of architectural
 blocks. By systematically analyzing the interplay between architecture, tokeniz
ation, and training across modalities, BioArc identifies novel hybrid architectu
res that surpass state-of-the-art models while being up to 25x smaller. We disti
ll these findings into empirical design principles and validate their biological
 relevance, demonstrating how our designs hierarchically capture the underlying
biological grammar. Additionally, we introduce an agentic framework to predict o
ptimal architectures for new tasks. Overall, BioArc provides a data-driven metho
dology for developing the next generation of efficient biological foundation mod
els and task-specific networks.

Magnitude Distance: A Geometric Measure of Dataset Similarity
Sahel Torkamani, Henry Gouk, Rik Sarkar
Quantifying the distance between datasets is a fundamental question in mathematics and machine learning. We propose *magnitude distance*, a novel distance metric defined on finite datasets using the notion of the *magnitude* of a metric space.

The proposed distance incorporates a tunable scaling parameter, t, that controls the sensitivity to global structure (small t) and finer details (large t). We prove several theoretical properties of magnitude distance, including its limiting behavior across scales and conditions under which it satisfies key metric properties.

In contrast to classical distances, we show that magnitude distance remains discriminative in high-dimensional settings when the scale is appropriately tuned.

We further demonstrate how magnitude distance can be used as a training objective for push-forward generative models. Our experimental results support our theoretical analysis and demonstrate that magnitude distance provides meaningful signals, comparable to established distance-based generative approaches.

The Axiomatic Value of Regularization in AI Alignment from Human Preferences
Ezgi Korkmaz
Reinforcement learning from human feedback is the leading approach to aligning powerful AI systems so that they can be safe and helpful for humanity. While RLHF is typically modelled as a problem of learning a single preference ranking from noisy feedback, true human preferences are complex and often conflicting, representing substantive disagreements stemming from the diversity of individual human values. With this motivation, a recent line of research has studied RLHF from the perspective of social choice theory, which provides a set of well-established desirable properties for aggregating diverse preferences. Seen through this lens, the standard learning objective in RLHF is equivalent to aggregating diverse human preferences via the Borda count rule. At the same time, several new RLHF algorithms have been proposed, which turn out to be equivalent to the von Neumann winner social choice rule. However, the connection between social choice theory and RLHF has thus far ignored the critical role of regularization to prevent divergence from a reference policy, which is utilized in essentially all practical RLHF algorithms. In this paper, we study how regularization affects the social choice axioms satisfied by different RLHF algorithms, and prove that regularization improves the axiomatic properties of the von Neumann winner rule. In contrast, the Borda count rule still fails to satisfy key social choice axioms even when regularized. These results provide a principled argument grounded in social choice theory for utilizing practical RLHF algorithms that correspond to the von Neumann winner, rather than the standard RLHF objective.

One Model to Translate Them All: Universal Any-to-Any Translation for Heterogeneous Collaborative Perception
Yang Li, Weize Li, Quan Yuan, Shao Congzhang, Guiyang Luo, Yunqi Ba, Xuanhan Zhu, Xinyuan Ding, Xiaoyuan Fu, Jinglin Li
By sharing intermediate features, collaborative perception extends each agent's sensing beyond standalone limits, but real-world feature modality heterogeneity remains a key barrier to effective fusion. Most existing methods, including direct adaption and protocol-based transforma-tion, typically rely on training adapters for newly emerging feature modalities and often require additional retraining or fine-tuning. Such repeated training is costly and is often infeasible across manufacturers due to model and data privacy con-straints, limiting real-world scalability. To address this issue, we propose UniTrans, a universal any-to-any feature modality translation model that instantiates translators on the fly for arbitrary modalities. UniTrans pretrains a bank of translator expert parameters and learns their combination coefficients as a function of source-to-target modality mapping. The mapping is measured in a modality-intrinsic latent space, wher

e an intrinsic encoder extracts modality-specific yet scene-invariant codes from single-frame intermediate features, enabling UniTrans to instantiate translators in a zero-shot manner. Experiments on OPV2V-H and DAIR-V2X demonstrate that UniTrans consistently outperforms state-of-the-art methods in both simulated and real-world set-tings, enabling efficient any-to-any translation through a universal model. Code will be made available.
****

FlowState: Sampling-Rate■Equivariant Time■Series Forecasting
Lars Graf, Thomas Ortner, Stanis■aw Wo■niak, Angeliki Pantazi
Existing time series foundation models (TSFMs), often based on transformer variants, lack adaptability to different sampling rates, struggle with generalization across varying context and target lengths and are computationally inefficient.
We introduce FlowState, a novel TSFM architecture that achieves sampling-rate–equivariant forecasting through a unified design that pairs a state space model (SSM) encoder with a functional basis decoder (FBD). This design enables continuous-time modeling and dynamic time-scale adjustment, allowing FlowState to inherently generalize across all possible temporal resolutions, and dynamically adjust the forecasting horizons without retraining. We further propose an efficient pretraining strategy that improves robustness and accelerates training. Despite being one of the smallest TSFMs, FlowState achieves state-of-the-art results on the widely used GIFT-Eval benchmark, while demonstrating superior adaptability to unseen sampling rates. Our detailed analyses confirm the effectiveness of its components, and we demonstrate its unique ability to adapt to varying input sampling rates.

Search or Accelerate: Confidence-Switched Position Beam Search for Diffusion Language Models
Mingyu Cao, Alvaro Correia, Christos Louizos, Shiwei Liu, Lu Yin
Diffusion Language Models (DLMs) generate text by iteratively denoising a masked sequence, repeatedly deciding which positions to commit at each step. Standard decoding follows a greedy rule, unmasking the most confident positions, yet this local choice can lock the model into a suboptimal unmasking order, especially on reasoning-heavy prompts. We present Search Or AcceleRate (SOAR), a training-free decoding algorithm that adapts its behavior to the model’s uncertainty. When confidence is low, SOAR briefly widens the search over alternative unmasking decisions to avoid premature commitments; when confidence is high, it collapses the search and decodes many positions in parallel to reduce the number of denoising iterations. Across mathematical reasoning and code generation benchmarks (GSM8K, MBPP, HumanEval) on Dream-7B and LLaDA-8B, SOAR improves generation quality while maintaining competitive inference speed, offering a practical way to balance quality and efficiency in DLM decoding.
****

SleepLM: Natural-Language Intelligence for Human Sleep
Zongzhe Xu, Zitao Shuai, Eideen Mozaffari, Ravi Shankar Aysola, Rajesh Kumar, Yuzhe Yang
We present SleepLM, a family of sleep-language foundation models that enable human sleep alignment, interpretation, and interaction with natural language.
Despite the critical role of sleep, learning-based sleep analysis systems operate in closed label spaces (e.g., predefined stages or events) and fail to describe, query, or generalize to novel sleep phenomena.
SleepLM bridges natural language and multimodal polysomnography, enabling language-grounded representations of sleep physiology.
To support this alignment, we introduce a multilevel sleep caption generation pipeline that enables the curation of the first large-scale sleep-text dataset, comprising over 100K hours of data from more than 10,000 individuals.
Furthermore, we present a unified pretraining objective that combines contrastive alignment, caption generation, and signal reconstruction to better capture physiological fidelity and cross-modal interactions.
Extensive experiments on real-world sleep understanding tasks verify that SleepLM outperforms state-of-the-art in zero-shot and few-shot learning, cross-modal r

etrieval, and sleep captioning. Importantly, SleepLM also exhibits intriguing ca
pabilities including language-guided event localization, targeted insight genera
tion, and zero-shot generalization to unseen tasks.
To support reproducibility and future work, we open-source the captioning pipeli
ne, pretrained checkpoints, and the model architectures at https://github.com/ya
ng-ai-lab/SleepLM.

Norm$\times$Direction: Restoring the Missing Query Norm in Vision Linear Attenti
on

Weikang Meng, Yadan Luo, Liangyu Huo, Yingjian Li, Yaowei Wang, Xin Li, Zheng Zh
ang

Linear attention mitigates the quadratic complexity of softmax attention but suf
fers from a critical loss of expressiveness. We identify two primary causes: (1)
 The normalization operation cancels the query norm, which breaks the correlatio
n between a query's norm and the spikiness (entropy) of the attention distributi
on as in softmax attention. (2) Standard techniques for enforcing non-negativity
 cause destructive information loss by nullifying valid inner-product interactio
ns. To address these challenges, we introduce **NaLaFormer**, a novel linear att
ention mechanism built upon a norm$\times$direction (ND) decomposition of the qu
ery and key vectors. We leverage each component to solve a distinct problem: The
 query norm is injected into our kernel to create a query-norm-aware map that
restores the attention distribution's spikiness. The *direction vectors* are pro
cessed by a geometric, cosine-based similarity metric that guarantees non-negati
vity while preserving the rich, fine-grained information of the inner product. W
e validate NaLaFormer through a comprehensive multi-modal evaluation, where it s
ets new state-of-the-art benchmarks for linear attention. Our model achieves up
to a 7.5\% accuracy gain on ImageNet-1K and a 4.7\% mIoU improvement on ADE20K o
ver comparable baselines. It demonstrates profound efficiency, reducing peak mem
ory by a transformative 92.3\% in token-intensive super-resolution tasks (70K+ t
okens). NaLaFormer's versatility is further confirmed as it surpasses strong bas
elines like Mamba on common-sense reasoning and sets a new state-of-the-art on t
he Long Range Arena (LRA) benchmark. Source code can be found in the supplementa
ry materials.

TIC-VLA: A Think-in-Control Vision-Language-Action Model for Robot Navigation in
 Dynamic Environments

Zhiyu Huang, Yun Zhang, Johnson Liu, Rui Song, Chen Tang, Jiaqi Ma

Robots in dynamic, human-centric environments must follow language instructions
while maintaining real-time reactive control. Vision-language-action (VLA) model
s offer a promising framework, but they assume temporally aligned reasoning and
control, despite semantic inference being inherently delayed relative to real-ti
me action. We introduce Think-in-Control (TIC)-VLA, a latency-aware framework th
at explicitly models delayed semantic reasoning during action generation. TIC-VL
A defines a delayed semantic-control interface that conditions action generation
 on delayed vision-language semantic states and explicit latency metadata, in ad
dition to current observations. We further propose a latency-consistent training
 pipeline that injects reasoning inference delays during imitation learning and
online reinforcement learning, aligning training with asynchronous deployment. T
o support realistic evaluation, we present DynaNav, a physics-accurate, photo-re
alistic simulation suite for language-guided navigation in dynamic environments.
 Extensive experiments in simulation and on a real robot show that TIC-VLA consi
stently outperforms prior VLA models while maintaining robust real-time control
under multi-second reasoning latency. Project website: https://ucla-mobility.git
hub.io/TIC-VLA/

Resilient Coresets and Clustering

Ashkan Norouzi-Fard, Silvio Lattanzi, Mohammadhossein Bateni, Morteza Monemizade
h

Many machine learning problems are geometric at their core, relying on metric
representations of data for tasks such as clustering, prototype selection,

nearest-neighbor search, and graph-based learning. Furthermore, data is constantly evolving and it is routinely transformed through dimensionality reduction, random
projections, feature embeddings, compression, or privacy-preserving mechanisms. These transformations are designed to preserve geometry approximately. As a result, they preserve objective values for many geometric optimization problems, but they fail to guarantee that
algorithmic outcomes remain consistent. In this work, we study \emph{resilient data summaries}
for geometric optimization. Building on the notion of
\emph{γ-resilient algorithms} from Ahmadian, we
introduce γ-resilient coresets. A γ-resilient
(k,ε)-coreset is a compact, weighted summary that guarantees a $(1+\varepsilon)$ approximation to the objective and enforces stability at the level of assignments. We complement our positive result with a lower bound showing that to obtain a tight approximation for resilient clustering it is necessary
to use a bi-criteria solution.

Navigating the Pareto Frontier of Alignment: Spectrum-Adaptive Fine-Tuning for LLMs

Yaoyou Fan, Chao Zhang, Xiaoyu Tan, Chenxing Sun, Yu Yuan, Haoyu Feng, Lu Pan, Ke Zeng, Xunliang Cai

Supervised Fine-Tuning with Negative Log-Likelihood (NLL) remains the standard post-training paradigm for Large Language Models, yet it imposes a disproportionately aggressive update force on low-probability target tokens.

This focus forces the model to prioritize minimizing the loss of difficult samples over optimizing the overall quality of the generation, often leading to unwarranted overconfidence.

On the other hand, alternatives like Dynamic Fine-Tuning suffer from vanishing gradients on these tokens, which severely hinders the acquisition of new concepts.

To bridge this gap, we propose **S**pectrum-**A**daptive **F**ine-**T**uning (**SAFT**), a unified framework that interpolates between the aggressive learning signal of NLL and the robust nature of probability-weighted optimization.

By adaptively balancing these objectives, SAFT effectively mitigates outlier sensitivity without sacrificing learning efficiency.

Empirically, our method achieves state-of-the-art performance on mathematical reasoning benchmarks, demonstrating superior generalization on out-of-distribution tasks. Furthermore, evaluations on general conversational alignment validate SAFT's broad adaptability across diverse data regimes. Our code is available at https://github.com/sjtu-scx/SAFT.

Coverage ≠ Exposure: Auditable Control of Same-Support Tail Failures under Multimodal Missingness

Ziteng Hong, Bingzhi Chen, Yishu Liu, Sudong Cai, Guangming Lu

Multimodal systems encounter partial observability from sensor dropout and degradation, yet adverse tails can remain unreliable even when average performance is preserved. Under a locked same-support contract, matched-average runs can exhibit same-support tail failure, diverging on worst-case and shift-reweighted metrics over the same observable support. The failure arises because conditional interaction separates environment coverage from parameter exposure. Gated routing sends information through different groups, so high-leverage groups may receive few updates despite complete coverage, and tail aggregation amplifies their errors. We audit this mismatch with TailPressure, an exposure-normalized statistic of tail-leveraged interaction from gating logs. We propose Heterogeneity-aware Closed-loop Exposure Stabilizer (H-CES), a lightweight controller that stabilizes per-group pressure via deterministic increment-branch gating and group-wise decoupled weight decay, without changing loss or inference. Across multimodal settings and backbones, H-CES improves same-support tail reliability while preserving cl

ean performance.

Divide-and-Denoise: A Game-Theoretic Method for Fairly Composing Diffusion Model
s
Abhi Gupta, Polina Barabanshchikova, Vikas K Garg, Samuel Kaski, Tommi Jaakkola
The abundance of pre-trained diffusion models provides an opportunity for compos
ition. Combining several models, however, runs the risk of one model dominating
or models disagreeing with each other. Here, we propose Divide-and-Denoise, a me
thod for coordinating multiple pre-trained diffusion models during sampling. Muc
h like managing a specialized workforce, our method creates a fair but efficient
division of labor across models. Central to our method is the notion of an allo
cation which defines the responsibility of each model to every region of the noi
sy sample. At every timestep, we then denoise by (i) updating the allocation by
solving a fair division game, where we divide the sample into regions that maxim
ize total utility under fairness constraints, and (ii) aligning the models with
this allocation, where we guide each model to denoise within its assigned region
. This leads to a new composite denoising process that evolves in tandem with a
division process. We evaluate Divide-and-Denoise on conditional image generation
. Across several quality metrics, including the GenEval benchmark, our method ou
tperforms baselines and resolves common failures including missing objects and m
ismatched attributes. Experiments show that Divide-and-Denoise utilizes each mod
el's expertise without neglecting any other model.
****
AD-MIR: Bridging the Gap from Perception to Persuasion in Advertising Video Unde
rstanding via Structured Reasoning
Binxiao Xu, Junyu Feng, Xiaopeng Lin, Haodong Li, ZhiYuan Feng, Bohan Zeng, Ruic
huan An, Ming Lu, Qi She, Wentao Zhang
Multimodal understanding of advertising videos is essential for interpreting the
intricate relationship between visual storytelling and abstract persuasion stra
tegies. However, despite excelling at general search, existing agents often stru
ggle to bridge the cognitive gap between pixel-level perception and high-level m
arketing logic. To address this challenge, we introduce **AD-MIR**, a framework
designed to decode advertising intent via a two-stage architecture. First, in th
e **Structure-Aware Memory Construction** phase, the system converts raw video i
nto a structured database by integrating semantic retrieval with exact keyword m
atching. This approach prioritizes fine-grained brand details, such as logos and
on-screen text, while dynamically filtering out irrelevant background noise to
isolate key protagonists. Second, the **Structured Reasoning Agent** mimics a ma
rketing expert through an iterative inquiry loop, decomposing the narrative to d
educe implicit persuasion tactics. Crucially, it employs an evidence-based self-
correction mechanism that rigorously validates these insights against specific v
ideo frames, automatically backtracking when visual support is lacking. Evaluati
on on the AdsQA benchmark demonstrates that AD-MIR achieves state-of-the-art per
formance, surpassing the strongest general-purpose agent, DVD, by 1.8 and 9.5 pe
rcentage points in strict and relaxed accuracy, respectively. These results unde
rscore that effective advertising understanding demands explicitly grounding abs
tract marketing strategies in pixel-level evidence. The code is available at [ht
tps://github.com/Little-Fridge/AD-MIR](https://github.com/Little-Fridge/AD-MIR).

Training-Free Guided Diffusion for Planning: A Unified Framework via Doob’s h-Tr
ansform with Safety Guarantees
Kenta Hoshino, Yashaswi Shashank Aluru, Xiyu Deng, Yorie Nakahira
This paper studies the theoretical foundations of guidance mechanisms in continu
ous-time score-based diffusion models.
We adopt Doob’s h-transform as a principled framework for characterizing ideal g
uided diffusion processes and analyze the discrepancy between ideal and approxim
ate guidance.
Our analysis provides explicit error bounds and yields probabilistic guarantees
on satisfying prescribed constraints, which are particularly important for safet
y-critical planning.

We further show that the Doob-based formulation induces a stochastic optimal control problem, enabling practical guidance design without additional model training.
We demonstrate the effectiveness of the proposed framework on robotic navigation tasks, including language-conditioned planning.
****
CAT-Q: Cost-efficient and Accurate Ternary Quantization for LLMs
Shigeng Wang, Chao Li, Yangyuxuan Kang, Jiawei Fan, Anbang Yao
In this paper, we present CAT-Q, **C**ost-efficient and **A**ccurate **T**ernary **Q**uantization, for compressing and accelerating LLMs. Unlike existing state-of-the-art ternary quantization methods that rely on data-intensive and costly quantization-aware training to mitigate severe performance degradation, CAT-Q is a simple yet effective post-training quantization scheme that is readily applicable to LLMs with diverse architectures and model sizes. It has two key components, learnable modulation (LM) and softened ternarization (ST), which are coupled from an optimization perspective. LM leverages a composition of learnable factors to modulate the distribution of pre-trained high-precision weights and the ternary threshold, making them less sensitive to ternarization. ST further introduces a differentiable transition function to guide the ternarization process toward stable convergence. We show that, for pre-trained LLMs with 1.7B to 8B parameters, CAT-Q can efficiently quantize them into ternary models using only 512 calibration samples, while achieving superior performance than the seminal BitNet 1.58-bit v1 and v2 families (with 1.3B to 7B parameters) trained with 100B tokens, yielding about a 100,000$\times$ reduction in training tokens. Moreover, we show for the first time that CAT-Q can quantize much larger pre-trained LLMs having 14B to 235B parameters into leading ternary models within just 8 to 60 hours on 8 A100-80GB GPUs. Code is available at https://github.com/IntelChina-AI/BitTern.
****
Understanding Behavior Cloning with Action Quantization
Haoqun Cao, Tengyang Xie
Behavior cloning is a fundamental paradigm in machine learning, enabling policy learning from expert demonstrations across robotics, autonomous driving, and generative models. Autoregressive models like transformer have proven remarkably effective, from large language models (LLMs) to vision-language-action systems (VLAs). However, applying autoregressive models to continuous control requires discretizing actions through quantization, a practice widely adopted yet poorly understood theoretically.

This paper provides theoretical foundations for this practice. We analyze how quantization error propagates along the horizon and interacts with statistical sample complexity. We show that behavior cloning with quantized actions and log-loss achieves optimal sample complexity—matching existing lower bounds—and incurs only polynomial horizon dependence on quantization error, provided the dynamics are stable and the policy satisfies a probabilistic smoothness condition. We further characterize when different quantization schemes satisfy or violate these requirements, and propose a model-based augmentation that provably improves the error bound without requiring policy smoothness. Finally, we establish fundamental limits that jointly capture the effects of quantization error and statistical complexity.
****
Detached Skip-Links and R-Probe: Decoupling Feature Aggregation from Gradient Propagation for MLLM OCR
Ziye Yuan, Ruchang Yao, Chengxin Zheng, Yusheng Zhao, Daxiang Dong, Ming Zhang
Multimodal large language models (MLLMs) excel at high-level reasoning yet fail on OCR tasks where fine-grained visual details are compromised or misaligned. We identify an overlooked optimization issue in multi-layer feature fusion. Skip pathways introduce direct back-propagation paths from high-level semantic objectives to early visual layers. This mechanism overwrites low-level signals and destabilizes training.

To mitigate this gradient interference, we propose Detached Skip-Links, a minimal modification that reuses shallow features in the forward pass while stopping gradients through the skip branch during joint training. This asymmetric design reduces gradient interference, improving stability and convergence without adding learnable parameters.
To diagnose whether fine-grained information is preserved and usable by an LLM, we introduce R-Probe, which measures pixel-level reconstructability of projected visual tokens using a shallow decoder initialized from the first quarter of the LLM layers.
Across multiple ViT backbones and multimodal benchmarks, and at scales up to 7M training samples, our approach consistently improves OCR-centric benchmarks and delivers clear gains on general multimodal tasks.

Towards Pareto-Optimal Tool-Integrated Agents with Pareto Ranking Policy Optimization
Junyi Li, Xiaowei Qian, Yingyi Zhang, Wenlin Zhang, Guojing Li, Sheng Zhang, Xiao Han, Yichao Wang, Xiangyu Zhao
Recent advances in tool-integrated language agents have significantly improved their ability to solve complex reasoning tasks. However, existing alignment methods predominantly focus on maximizing task accuracy, while overlooking auxiliary objectives such as tool-use efficiency, which are essential for practical deployment. To address this gap, we introduce \textbf{ParetoPO}, a two-stage multi-objective optimization framework for aligning tool-using large language models (LLMs) under competing objectives. In the first stage, ParetoPO leverages hypervolume-guided dynamic scalarization to adapt reward weights based on global Pareto frontier progress. In the second stage, it replaces scalarized learning signals with Pareto-ranking-based advantage computation, promoting nondominated trajectories through dominance-aware credit assignment. This design enables fine-grained, action-level optimization across multiple conflicting objectives. Experimental results on mathematic reasoning and multi-hop QA tasks show that ParetoPO consistently discovers policies with superior accuracy-efficiency trade-offs compared to static and heuristic baselines. Our code is publicly available at https://github.com/Applied-Machine-Learning-Lab/ICML2026_ParetoPO.

Performative Policy Gradient: Optimality in Performative Reinforcement Learning
Debabrota Basu, Udvas Das, Brahim Driss, Uddalak Mukherjee
Post-deployment machine learning algorithms often influence the environments they act in, and thus *shift* the underlying dynamics that the standard reinforcement learning (RL) methods ignore. While designing optimal algorithms in this *performative* setting has recently been studied in supervised learning, the RL counterpart remains under-explored. In this paper, we prove the performative counterparts of the performance difference lemma and the policy gradient theorem in RL, and introduce the **Performative Policy Gradient** algorithm **PePG**. **PePG** is the first policy gradient algorithm designed to account for performativity in RL. Under softmax parametrisation, and also with and without entropy regularisation, we prove that **PePG** converges to *performatively optimal policies*, i.e. policies that remain optimal under the distribution shifts induced by themselves. Thus, **PePG** significantly extends the prior works in Performative RL that achieves *performative stability* but not optimality. Our empirical analysis on standard performative RL environments validate that **PePG** outperforms the existing performative RL algorithms aiming for stability.

When Planning Fails Despite Correct Execution: On Epistemic Calibration for LLM-Based Multi-Agent Systems
Zehao Wang, Shilong Jin, Zhao Cao, Lanjun Wang
LLM-based multi-agent systems can fail even when planned actions are executed correctly because agents may misjudge their knowledge when evaluating plan feasibility, a phenomenon we term epistemic miscalibration in planning. Unlike execution errors, epistemic miscalibration is latent during planning, as generated plans can remain self-consistent and executable without observable errors; the miscal

ibration is also dynamic, as new information can alter feasibility assessments, potentially obscuring past miscalibration signals and causing them to recur over time. To address this, we propose the Epistemic Planning Calibration Agentic Workflow (EPC-AW), which assesses whether plans remain supported under varying information conditions rather than directly verifying feasibility.
EPC-AW employs Information-consistency-based Plan Selection, selecting plans whose evaluations are stable across agents, together with Consistency-guided Epistemic State Refinement to adapt calibration over time by leveraging past discrepancies to guide future planning. Experiments show that EPC-AW improves system-level success by an average of 9.75\%. Code is available in the public repository (https://github.com/wzhSteve/EPC-AW).

OSAQ: Outlier Self-Absorption for Accurate Low-bit LLM Quantization
Zhikai Li, Zhen Dong, Xuewen Liu, Jing Zhang, Qingyi Gu
Large Language Models (LLMs) have demonstrated remarkable capabilities in understanding and generation tasks. However, their massive parameter scale leads to significant resource consumption and latency during inference. Post-training weight-only quantization offers a promising solution by reducing model size and accelerating token generation through alleviating the memory-bound issue. Nevertheless, there are inherent systematic outliers in weights, and although some efforts have attempted to address them, such as scaling and rotation, the performance of low-bit quantization remains far from satisfactory. In this paper, we propose Outlier Self-Absorption Quantization (OSAQ), which performs second-order low-rank derived additive weight suppression for low-bit weight-only LLM quantization. Specifically, we observe that Hessian exhibits low-rank consistency across different inputs, with certain directions persistently lacking strength. Leveraging this property, we construct an additive weight transformation based on the Hessian ’s null space, thereby suppressing weight outliers without affecting the task loss. This additive transformation can be absorbed into the weights offline, requiring no inter-layer transformations and introducing no inference overhead. Moreover, the construction is efficiently achieved by a closed-form solution, without resource-intensive training or iterative procedures. Extensive experiments across models of varying scales and tasks are conducted, and the results show that OSAQ effectively suppresses outliers and improves low-bit quantization performance.

Beyond Accuracy and Complexity: The Effective Information Criterion for Structurally Stable Symbolic Regression
Zihan Yu, Guanren Wang, Jingtao Ding, Huandong Wang, Yong Li
Symbolic regression (SR) traditionally balances accuracy and complexity, implicitly assuming that simpler formulas are structurally more rational. We argue that this assumption is insufficient: existing algorithms often exploit this metric to discover accurate and compact but structurally irrational formulas that are numerically ill-conditioned and physically inexplicable. Inspired by the structural stability of real physical laws, we propose the Effective Information Criterion (EIC) to quantify formula rationality. EIC models formulas as information channels and measures the amplification of inherent rounding noise during recursive calculation, effectively distinguishing physically plausible structures from pathological ones without relying on ground truth. Our analysis reveals a stark structural stability gap between human-derived equations and SR-discovered results. By integrating EIC into SR workflows, we provide explicit structural guidance: for heuristic search, EIC steers algorithms toward stable regions to yield superior Pareto frontiers; for generative models, EIC-based filtering improves pre-training sample efficiency by 2–4 times and boosts generalization R^2 by 22.4\%. Finally, an extensive study with 108 human experts shows that EIC aligns with human preferences in 70\% of cases, validating structural stability as a critical prerequisite for human-perceived interpretability. We release our code at https://github.com/tsinghua-fib-lab/EIC

Learning Manifold Data with Flow Matching

Sophia Pi, Mingcheng Lu, Maojiang Su, Weimin Wu, Jerry Yao-Chieh Hu, Han Liu
We study flow-matching transformers when data lie on a low-dimensional manifold.

Our key insight is a flow decomposition that splits motion along the manifold fr
om motion off the manifold.
The scheme works for first and higher-order flow matching and ties model complex
ity to the intrinsic manifold dimension.
Building on these, we establish tighter sample-complexity bounds for velocity ap
proximation, velocity estimation, and distribution estimation.
Our results show how flow-matching transformers escape the curse of dimensionali
ty by utilizing intrinsic data structure.

Very Efficient Listwise Multimodal Reranking for Long Documents
Yiqun Sun, Pengfei Wei, Lawrence B. Hsieh
Listwise reranking is a critical yet costly component in vision-centric retrieva
l and multimodal retrieval-augmented generation (M-RAG) over long documents. Alt
hough recent VLM-based rerankers achieve strong accuracy, they are often impract
ical due to long visual-token inputs and autoregressive decoding, resulting in h
igh latency. We propose ZipRerank, a very efficient listwise multimodal reranker
 that directly addresses both bottlenecks: it shortens the input via query-image
 early interaction and eliminates multi-step generation by scoring all candidate
s in a single forward pass. ZipRerank is trained with a two-stage recipe: listwi
se pretraining on large-scale text reranking data rendered as images, followed b
y multimodal finetuning with VLM-teacher supervision and a soft-ranking objectiv
e to handle noisy rankings. Extensive experiments on the MMDocIR benchmark demon
strate that ZipRerank matches or surpasses state-of-the-art multimodal rerankers
 while reducing LLM inference latency by up to an order of magnitude, making it
well-suited for latency-sensitive real-world systems. Source code is available a
t https://anonymous.4open.science/r/ZipRerank.

View Space: Learning Representation across Arbitrary Graphs
Dooho Lee, Myeong Kong, Minho Jeong, Jaemin Yoo
Generalizing pretrained models to unseen datasets without retraining is a centra
l challenge toward foundation models. Achieving fully inductive inference on num
erical data is particularly difficult due to large variations in feature dimensi
onality and semantics across datasets. We observe that, in the presence of graph
 structure, numerical data admits a distinct structure-induced representational
axis beyond the feature space, which we formalize as the *view space*. This view
 space enables a unified representation of graphs with heterogeneous features an
d motivates *Graph View Transformation* (GVT), a class of parametric mappings th
at can be shared across arbitrary graphs. We instantiate this framework with Rec
urrent GVT, an architecture for fully inductive node representation learning in
node classification. Pretrained on OGBN-Arxiv and evaluated on 27 benchmarks, Re
current GVT outperforms GraphAny, the prior fully inductive graph model, by +8.9
3%, and surpasses 12 individually tuned GNNs by at least +3.30%. These results e
stablish the view space as a principled and practical foundation for learning ac
ross graphs with heterogeneous feature spaces. Code and checkpoints are availabl
e
in https://github.com/dooho00/graph-view-space.

Analytic Bijections for Smooth and Interpretable Normalizing Flows
Mathis Gerdes, Miranda C. N. Cheng
A key challenge in normalizing flows is finding expressive invertible scalar bij
ections. Existing approaches face trade-offs: affine transformations are smooth
and analytically invertible but lack expressivity; monotonic splines offer local
 control but are only piecewise smooth and act on bounded domains; residual flow
s achieve smoothness but need numerical inversion. We introduce three families o
f *analytic bijections* that are globally smooth (C^∞), defined on all of
 $\mathbb{R}$, and analytically invertible in closed form, combining the favorab
le properties of prior approaches. Beyond serving as drop-in replacements in cou

pling flows, where they match or exceed spline performance, we develop *radial flows*: a novel architecture using direct parametrization that transforms the radial coordinate while preserving angular direction. Radial flows exhibit exceptional training stability, produce geometrically interpretable transformations, and on targets with radial structure can achieve comparable quality to coupling flows with $1000\times$ fewer parameters. We provide comprehensive evaluation on 1D and 2D benchmarks, and demonstrate applicability to higher-dimensional physics problems through experiments on ϕ^4 lattice field theory, where our bijections outperform affine baselines and enable problem-specific designs that address mode collapse.

Rethinking Feature Alignment in Generalist Graph Anomaly Detection: A Relational Fingerprint-based Approach
Yujing Liu, Yixin Liu, Yu Zheng, Alan Wee-Chung Liew, Xiaofeng Cao, Shirui Pan
Extending traditional graph anomaly detection (GAD) from one-for-one to one-for-all paradigms, generalist GAD aims to learn a universal detector for identifying anomalies on unseen graphs without graph-specific retraining. Nevertheless, existing approaches primarily focus on aligning heterogeneous features across different data domains via PCA-based projection, which harmonizes feature dimensions but neglects semantic alignment. As a result, GAD models fail to acquire semantically transferable knowledge from source-domain pre-training, and even exhibit negative transfer on unseen graphs. To address this issue, we propose a Relational Fingerprint-based generalist GAD approach (REFI-GAD for short), aligning heterogeneous raw features with a universal and semantics-aware relational fingerprint (REFI) that encodes anomaly-indicative cues from both contextual and structural perspectives. Building on REFI, we design a fingerprint-grounded generalist GAD model, which combines a transformer-based encoder to capture domain-invariant knowledge with an SNR-guided refinement module for domain-specific adaptation. Extensive experiments on 14 datasets demonstrate that REFI-GAD significantly outperforms state-of-the-art methods.
****

Learning Treatment Allocations with Risk Control Under Partial Identifiability
Sofia Ek, Dave Zachariah
Learning beneficial treatment allocations for a patient population is an important problem in precision medicine. For such allocations, a certain proportion of treated patients may not receive any benefit. This proportion of unnecessary treated represents a `treatment risk' which is a waste of resources and may, in addition, expose patients to unnecessary adverse effects. Therefore, we aim to control the treatment risk when learning beneficial allocations. This learning problem is complicated by the fact that the treatment risk is generally not identifiable from either randomized trial or observational data. We propose a certifiable learning method that controls treatment risk, using finite samples in the partially identified setting. The method is illustrated using both simulated and real data.

Skill-Pro: Learning Reusable Skills from Experience via Non-Parametric PPO for LLM Agents
Qirui Mi, Zhijian Ma, Mengyue Yang, Haoxuan Li, Yisen Wang, Haifeng Zhang, Jun Wang
LLM-driven agents excel at sequential decision-making but often rely on on-the-fly reasoning, re-deriving solutions even in recurring scenarios. This insufficient experience reuse leads to computational redundancy and instability. To bridge this gap, we propose **Skill-Pro**, a framework enabling agents to autonomously learn reusable procedural skills from interaction experiences without parameter updates. By formalizing a **Skill-MDP**, Skill-Pro transforms passive episodic narratives into executable Skills defined by activation, execution, and termination conditions to ensure executability.
To achieve reliable reusability without capability degradation, we introduce **Non-Parametric PPO**, which leverages semantic gradients for high-quality candidate generation and a PPO Gate for robust Skill verification. Through score-based

maintenance, Skill-Pro sustains compact, high-quality procedural memory. Experimental results across in-domain, cross-task, and cross-agent scenarios demonstrate that Skill-Pro achieves superior reuse rates and significant gains with extreme memory compression. Visualized evolutionary trajectories and Skill distributions further reveal how Skill-Pro transparently accumulates, refines, and reuses procedural knowledge to facilitate long-term autonomy.

Monitorability as a Free Gift: How RLVR Spontaneously Aligns Reasoning

Zidi Xiong, Shan Chen, Himabindu Lakkaraju

As Large Reasoning Models (LRMs) are increasingly deployed, auditing their chain-of-thought (CoT) traces for safety becomes critical. Recent work has reported that monitorability—the degree to which CoT faithfully and informatively reflects internal computation—can appear as a "free gift" during the early stages of Reinforcement Learning with Verifiable Rewards (RLVR).

We make this observation concrete through a systematic evaluation across model families and training domains.

Our results show that this effect is not universal: monitorability improvements are strongly data-dependent. In particular, we demonstrate the critical role of data diversity and instruction-following data during RLVR training. We further show that monitorability is orthogonal to capability—improvements in reasoning performance do not imply increased transparency. Through mechanistic analysis, we attribute monitorability gains primarily to response distribution sharpening (entropy reduction) and increased attention to the prompt, rather than stronger causal reliance on reasoning traces. We also reveal how monitorability dynamics vary with controlled training and evaluation difficulty. Together, these findings provide a holistic view of how monitorability emerges under RLVR, clarifying when gains are likely to occur and when they are not.

Kalman Linear Attention: Parallel Bayesian Filtering For Efficient Language Modeling and State Tracking

Vaisakh Shaj, Cameron Barker, Aidan Scannell, Andras Szecsenyi, Elliot J. Crowley, Amos Storkey

State-space language models such as Mamba and gated linear attention (GLA) offer efficient alternatives to transformers due to their linear complexity and parallel training, but often lack the expressivity and robust state-tracking needed for complex reasoning. We address these limitations by reframing sequence modelling through a probabilistic lens, using Bayesian filters as a core primitive. While classical filters such as Kalman filters provide principled state estimation and uncertainty tracking, they are typically viewed as inherently sequential. We show that reparameterising the Kalman filter in information form enables its updates to be computed via an associative scan, allowing efficient parallel training. Building on this insight, we introduce the Kalman Linear Attention (KLA) layer, a neural sequence-modelling primitive that performs time-parallel probabilistic inference while maintaining explicit belief-state uncertainty. KLA offers strictly more expressive non-linear updates and gating than GLA variants while retaining their computational advantages. On language modelling tasks, KLA matches or outperforms modern SSMs and GLAs across representative benchmarks for discrete token manipulation and state tracking.

Quantifying the Uncertainty of Foundation Models with Singular Value Ensembles

Mehmet Ozgur Turkoglu, Dominik J. Mühlematter, Alexander Becker, Konrad Schindler, Helge Aasen

Foundation models have become a dominant paradigm in machine learning, achieving remarkable performance across diverse tasks through large-scale pretraining. However, they often yield overconfident, uncalibrated predictions. The standard approach to quantifying epistemic uncertainty are ensembles of multiple independently trained models. But their computational cost scales linearly with ensemble size, making them impractical for large foundation models. We propose Singular Value Ensemble (SVE), a parameter-efficient implicit ensembling method. SVE builds on a simple, but powerful core assumption: namely, that the singular vectors of

the weight matrices correspond to meaningful directions in the representation space. If the singular vectors are indeed meaningful (orthogonal) "knowledge directions", then a model ensemble can be obtained by modulating only how strongly each direction contributes to the output. Rather than learning new parameters for each ensemble member, we freeze the singular vectors and only train per-member singular values that rescale the contribution of each direction in that shared knowledge basis. Ensemble diversity emerges naturally during joint training as stochastic initialization and random batch sampling cause different members to converge to different combinations of the same underlying knowledge. SVE performs comparable to an explicit ensemble, while increasing the parameter count of the base model by <1%, making principled uncertainty estimation accessible in resource-constrained settings. We validate SVE on NLP and vision tasks with various different backbones and show that it improves calibration while maintaining predictive accuracy.

Left–Right Symmetry Breaking in CLIP-Style Vision-Language Models Trained on Synthetic Spatial-Relation Data

Takaki Yamamoto, Chihiro Noguchi, Toshihiro Tanizawa

Spatial understanding remains a key challenge in vision-language models. Yet it is still unclear whether such understanding is truly acquired, and if so, through what mechanisms. We present a controllable 1D image–text testbed to probe how left–right relational understanding emerges in Transformer-based vision and text encoders trained with a CLIP-style contrastive objective. We train lightweight Transformer-based vision and text encoders end-to-end on paired descriptions of one- and two-object scenes and evaluate generalization to unseen object pairs while systematically varying label and layout diversity. We find that contrastive training learns left–right relations and that label diversity, more than layout diversity, is the primary driver of generalization in this setting. To gain the mechanistic understanding, we perform an attention decomposition and show that interactions between positional and token embeddings induce a horizontal attention gradient that breaks left–right symmetry in the encoders; ablating this contribution substantially reduces left–right discrimination. Our results provide a mechanistic insight of when and how CLIP-style models acquire relational competence.

Riemannian Optimization for Fair Spectral Clustering

Minh Phu Vuong, Jinyoung Lee, Young-Ju Lee, Chul-Ho Lee

Fair graph clustering has emerged as a critical research area for addressing algorithmic bias in machine learning. The objective is to ensure that the proportion of each protected group within a cluster is consistent with its representation in the entire dataset. However, most existing spectral solutions rely on computationally expensive eigendecompositions of the graph Laplacian, limiting their scalability. In this paper, we propose Riemannian Fair Spectral Clustering (R-FairSC), a novel method that formulates fair spectral clustering as a constrained optimization problem on a Riemannian manifold. We develop a Riemannian alternating direction method of multipliers employing a variable-splitting strategy to efficiently solve the associated subproblems. Numerical experiments on large synthetic and real-world graphs demonstrate that R-FairSC significantly improves computational efficiency over state-of-the-art methods while maintaining high clustering quality and fairness.

****

SC-FAGC: Size Constrained Fast Anchor-based Graph Clustering

Liu Jiachen

Spectral clustering is hindered by its $O(n^{3})$ time complexity, and although anchor-based approximations reduce this to $O(nm^{2})$ ($m \ll n$), they often yield degenerate or unbalanced partitions in the absence of explicit cluster-size control. To address this limitation, we propose \textbf{SC-FAGC (Size-Constrained Fast Anchor Graph Clustering)}, a unified formulation that integrates entropy regularization and bilateral cardinality constraints within an anchor-based spectral clustering framework, enforcing user-specified lower and upper bounds on a

nchor-level cluster sizes to avoid trivial or highly unbalanced solutions. To so lve the resulting non-convex problem efficiently, we develop an \textbf{Iterativ ely Re-weighted (IRW)} optimization scheme that linearizes the objective and sol ves each subproblem via a \textbf{Double-Bounded Optimal Transport (DB-OT)} solv er based on the \textbf{Sinkhorn--Knopp} algorithm, guaranteeing convergence whi le maintaining scalability. Extensive experiments on benchmark datasets demonstr ate that SC-FAGC consistently achieves state-of-the-art performance across six s tandard clustering metrics while strictly enforcing the prescribed anchor-level constraints. Moreover, it induces effective data-level size control after label transmission, offering a principled and scalable solution for large-scale graph clustering with controllable partition structure.

SpanNorm: Reconciling Training Stability and Performance in Deep Transformers
Wang Chao, Bei Li, Jiaqi Zhang, Xinyu Liu, Yuchun Fan, Linkun Lyu, Xin Chen, Jin gang Wang, Tong Xiao, Peng Pei, Xunliang Cai
The success of Large Language Models (LLMs) hinges on the stable training of dee p Transformer architectures. A critical design choice is the placement of normal ization layers, leading to a fundamental trade-off: the ''PreNorm'' architecture ensures training stability at the cost of potential performance degradation in deep models, while the ''PostNorm'' architecture offers strong performance but s uffers from severe training instability. In this work, we propose SpanNorm, a no vel technique designed to resolve this dilemma by integrating the strengths of b oth paradigms. SpanNorm adopts the clean residual path of PreNorm to stabilize s ignal propagation while employing a PostNorm-style computation that normalizes t he output of the residual connection, thereby enhancing model performance. We pr ovide a theoretical analysis demonstrating that SpanNorm, combined with a princi pled scaling strategy, maintains bounded signal variance throughout the network, preventing the gradient issues that plague PostNorm models, and alleviating the representation collapse of PreNorm. Empirically, SpanNorm consistently outperfo rms standard normalization schemes in both dense and Mixture-of-Experts (MoE) sc enarios, paving the way for more powerful and stable Transformer architectures.

CoPE: A Framework for Optimizing Coordination between Planning and Execution in LLM-based Agents
Huanxi Liu, Kun Hu, Qiang Wang, Yuanzhao Zhai, Feng Dawei, Bo Ding, Huaimin Wang
Fine-tuning Large Language Models (LLMs) as autonomous agents on domain-specific data has emerged as a promising paradigm for tackling interactive, real-world t asks.
However, existing studies have overlooked the critical coordination between long -term planning and multi-step execution in optimizing agent capabilities.
This oversight leads to the propagation of impractical plans and plan-deviated t rajectories within the optimization process, resulting in suboptimal task perfor mance and hindering the further development of LLM-based agents in long-horizon tasks.

To bridge this gap, we propose $\textbf{CoPE}$, a novel framework that explicitl
y integrates planning–execution coordination into LLM-based agent optimization.
CoPE employs Self-Refining MCTS to generate task plans and multiple execution tr
ajectories through environment interactions.
By quantifying the coordination between planning and execution, CoPE assigns hig
her optimization weights to well-coordinated samples, enabling LLM-based agents
to learn better planning and execution policies.
Extensive experiments demonstrate that CoPE substantially improves agent coordin
ation, outperforming state-of-the-art baselines on benchmarks comprising two lon
g-horizon multi-step tasks. Codes and data are available at https://github.com/O
ctobrist/CoPE.

A Cartesian-3j Framework for Machine Learning Interatomic Potentials
Zemin Xu, Chenyu Wu, Wenbo Xie, Peijun Hu
Machine learning interatomic potentials (MLIPs) have brought substantial gains i
n the extrapolation capability in computational chemistry. However, most equivar
iant models are typically built with spherical tensors (STs), while Cartesian te
nsor formulations remain less developed despite their natural alignment with ato
mic coordinates and tensorial targets. In this work, we develop a Cartesian fram
ework for irreducible Cartesian tensors (ICTs) by introduce the Cartesian-3j sym
bol and Cartesian Generalized Clebsch-Gordan Coefficients, which serve as direct
 analogues of the Wigner-3j symbol and Generalized Clebsch-Gordan coefficients d
efined for ST coupling. We extend the e3nn library to support ICT product, and u
se this framework to build Cartesian counterparts of MACE, NequIP, and Allegro,
allowing the first controlled comparison where architectures are held fixed and
only the tensor basis is changed. Our experiments show that irreducible Cartesia
n models can achieve accuracy comparable to spherical counterparts, but direct C
artesianization incurs unfavorable compute and memory scaling, motivating dedica
ted Cartesian architectural choices. Leveraging ICTs and our framework, we intro
duce TACE-v1-OAM-M and demonstrate that it achieves competitive performance on M
atbench Discovery compared to state-of-the-art ST models.

Efficient Mismatch-Tolerant Coding for Model-Driven Compression
Aviv Adler, Jennifer Tang
A central insight in lossless data compression is
the close connection between probabilistic next-
symbol prediction and efficient sequence compression, whereby predictive models
can be combined with classical coding techniques to achieve
strong compression performance. Applying this
approach with powerful modern learned models, such as LLMs, has been shown to ac
hieve
markedly better compression than traditional
techniques across a wide range of domains.
However, significant practical challenges remain,
including model non-determinism, in which a
model produces different predictions on different machines despite identical par
ameters and inputs; such mismatches between the encoder and
decoder can lead to complete decoding failure.
Probability Matching Interval Coding (PMATIC)
was recently introduced as a drop-in framework
for mismatch-robust coding and shown to enable
reliable compression and decompression in the
presence of bounded prediction mismatch (Adler
& Tang, 2026). In this work, we present a generalization of PMATIC that allows t
he incorpo-
ration of tight theoretical results into the design
and more flexible parameter optimization, resulting in substantial improvements
in compression
efficiency and robustness.

Approximation Preserving Coresets
Milind Prabhu, Chris Schwiegelshohn, Sudarshan Shyam
Clustering in a big data setting is an intensively studied problem, with coresets emerging as one of the important paradigms in this line of work. Given a cost function $\text{cost}(P,S)$ mapping input points P and a solution S to an objective value, a coreset is a typically weighted sketch $\Omega\subseteq P$ such that $\text{cost}(\Omega,S)\approx \text{cost}(P,S)$. In practice, coreset sizes much smaller than those suggested by theoretical guarantees are often found to be sufficient.

In this paper, we offer an explanation for this phenomenon. Smaller coreset sizes suffice if we only wish to preserve the costs of \emph{good} solutions, i.e., solutions with low cost. We define and devise \emph{approximation-preserving coresets}, which provide a weaker guarantee than strong coresets, which apply to all solutions, while providing stronger guarantees than weak coresets, which apply only to the optimum solution. We complement this result by showing that even a very small distortion in the approximation factor cannot admit coresets of this size.
****
GAM-RAG: Gain-Adaptive Memory for Evolving Retrieval in Retrieval-Augmented Generation
Yifan Wang, Mingxuan Jiang, Zhihao Sun, Yixin Cao, Yicun Liu, Keyang Chen, Guangnan Ye, Hongfeng Chai
Retrieval-Augmented Generation (RAG) grounds large language models with external evidence, but many implementations rely on pre-built indices that remain static after construction. Related queries therefore repeat similar multi-hop traversal, increasing latency and compute. Motivated by schema-based learning in cognitive neuroscience, we propose GAM-RAG, a training-free framework that accumulates retrieval experience from recurring or related queries and updates retrieval memory over time. GAM-RAG builds a lightweight, relation-free hierarchical index whose links capture potential co-occurrence rather than fixed semantic relations. During inference, successful retrieval episodes provide sentence-level feedback, updating sentence memories so evidence useful for similar reasoning types becomes easier to activate later. To balance stability and adaptability under noisy feedback, we introduce an uncertainty-aware, Kalman-inspired gain rule that jointly updates memory states and uncertainty estimates. It applies fast updates for reliable novel signals and conservative refinement for stable or noisy memories. We provide a theoretical analysis of the update dynamics, and empirically show that GAM-RAG improves average performance by 3.95\% over the strongest baseline and by 8.19\% with 5-turn memory, while reducing inference cost by 61\%.
****
Shuffle the Context: RoPE-Perturbed Self-Distillation for Long-Context Adaptation
Zichong Li, Chen Liang, Liliang Ren, Tuo Zhao, yelong shen, Weizhu Chen
Large language models (LLMs) increasingly operate in settings that require reliable long-context understanding, such as retrieval-augmented generation and multi-document reasoning. A common strategy is to fine-tune pretrained short-context models at the target sequence length. However, we find that standard long-context adaptation can remain brittle: model accuracy depends strongly on the absolute placement of relevant evidence, exhibiting high positional variance even when controlling for task format and difficulty.
We propose *RoPE-Perturbed Self-Distillation*, a training regularizer that improves positional robustness. The core idea is to form alternative ``views'' of the same training sequence by perturbing its RoPE indices---effectively moving parts of the context to different positions---and to train the model to produce consistent predictions across views via self-distillation. This encourages reliance on semantic signals instead of brittle position dependencies.
Experiments on long-context adaptation of Llama-3-8B and Qwen-3-4B demonstrate consistent gains on long-context benchmarks, including up to 12.04 percent-point improvement on RULER-64K for Llama-3-8B and 2.71 percent-point gain on RULER-256K for Qwen-3-4B after SFT, alongside improved length extrapolation beyond the tr

aining context window.

From Memorization to Parameter Interference: How Overtraining Experts Harms Model Merging
Stefan Horoi, Guy Wolf, Eugene Belilovsky, Gintare Karolina Dziugaite
Modern deep learning is increasingly characterized by the use of open-weight foundation models that can be fine-tuned on specialized datasets. This has led to a proliferation of expert models and adapters, often shared via platforms like HuggingFace and AdapterHub. Model merging has recently emerged as an effective way to leverage these existing resources, enabling the composition of capabilities from different model checkpoints. A natural pipeline has thus formed to harness the benefits of transfer learning and amortize sunk training costs: models are pre-trained on general data, fine-tuned on specific tasks, and then multiple checkpoints are merged to obtain a more capable model. A prevailing assumption is that improvements at one stage of this pipeline propagate downstream, leading to gains at subsequent steps. In this work, we challenge that assumption by examining how expert fine-tuning affects model merging. We show that long fine-tuning of experts that optimizes for their individual performance leads to degraded merging performance across vision and language modalities, multiple model scales, and both fully fine-tuned and LoRA-adapted models. We trace this degradation to the memorization of a small set of difficult examples that dominate late fine-tuning steps. This causes negative parameter interference and encodes knowledge that is forgotten during merging. Finally, we demonstrate that task-dependent aggressive early stopping strategies can significantly improve model merging performance.
****
Search for Truth from Reasoning: A Dynamic Representation Editing Framework for Steering LLM Trajectories
Tianlong Wang, Yuhang Wang, Weibin Liao, Xin Gao, Xinyu Ma, Yang Lin, Yasha Wang, Liantao Ma
Current approaches to enhance Large Language Model (LLM) reasoning, such as Chain-of-Thought and "Wait" prompts, primarily encourage models to think more, yet often fail to guide them toward Truth. While Representation Editing (RepE) offers a intrinsic control, its application to dynamic reasoning trajectories remains underexplored. In this work, we bridge this gap by investigating the geometry of truth within unfolding reasoning chains. We uncover three critical insights: (1) Truth is encoded at the sentence level and is entangled with latent reasoning patterns; (2) Effective intervention follows an Uncertainty Principle and a Decay Effect, requiring localization to early, high-entropy forks; (3) Naive steering vectors suffer from noise, risking collateral damage to correct trajectories. Based on these findings, we propose DynaSteer, a dynamic RepE framework. DynaSteer employs pattern clustering to disentangle reasoning manifolds and utilizes Fisher-LDA to project purified truth. By dynamically monitoring lookahead entropy, it selectively steers and rolls back trajectories only when necessary. Comprehensive experimental results on several MATH benchmark verify the effectiveness of DynaSteer, and experiments on out-of-domain coding tasks further confirm its generalization ability. Our code is publicly available at https://github.com/tianlwang/DynaSteer.
****
Demystifying When Pruning Works via Representation Hierarchies
Shwai He, Guoheng Sun, Haichao Zhang, Yun Fu, Ang Li
Network pruning, which removes less important parameters or architectures, is often expected to improve efficiency while preserving performance. However, this expectation does not consistently hold across language tasks: pruned models can perform well on non-generative tasks but frequently fail in generative settings. To demystify how such discrepancies arise under pruning, we analyze network pruning from a representation-hierarchy perspective, decomposing the internal computation of language models into three sequential spaces: \textit{embedding} (hidden representations), \textit{logit} (pre-softmax outputs), and \textit{probability} (post-softmax distributions).

While representations in the embedding and logit spaces are largely robust to pruning-induced perturbations, the subsequent nonlinear transformation from logits to the probability space amplifies such deviations, whose persistence across time steps leads to substantial degradation during generation.
By contrast, the stability of the categorical-token probability subspace, together with the robustness of the embedding space, supports the effectiveness of pruning for non-generative tasks such as retrieval and multiple-choice classification. Our representation-level analysis disentangles the effects of pruning across tasks and offers practical guidance for applying pruning effectively.
The code is available in the \href{https://github.com/CASE-Lab-UMD/Pruning-on-Representations}{project repository}.

Intrinsic Gradient Suppression for Label-Noise Prompt Tuning in Vision–Language Models
Jia-yu Li, Jiaxin Qi, Sheng Zhou, Jianqiang Huang, Xian-Sheng Hua
Contrastive vision-language models like CLIP exhibit remarkable zero-shot generalization. However, prompt tuning remains highly sensitive to label noise, as mislabeled samples generate disproportionately large gradients that can overwhelm pre-trained priors.
We argue that because CLIP already provides a near-optimal initialization, adaptation should be inherently conservative, particularly against the extreme gradient updates common in noisy settings.
To this end, we propose Double-Softmax Prompt Tuning (DSPT), a hyperparameter-free method for intrinsic gradient suppression. By applying a sequential probabilistic normalization, DSPT induces a self-adaptive saturation zone that suppresses gradients from high-error noisy samples while maintaining informative updates.
We also provide both theoretical analysis and empirical evidence about how this mechanism achieves adaptive suppression.
This design transforms ``gradient vanishing'', traditionally a training bottleneck, into a principled noise-filtering shield for label-noise prompt tuning. Extensive experiments confirm that this simple, drop-in design achieves state-of-the-art robustness across various noisy benchmarks, outperforming methods with complex architectures and handcrafted hyperparameters.

Beyond Single Embedding: Modeling User Preferences as Distribution in Federated Recommendation
Chunxu Zhang, Weipeng Zhang, Guodong Long, Zhiheng Xue, Bo Yang
Most federated recommender systems represent each user with a single embedding learned from local interaction data, implicitly assuming that user preferences are fixed and precisely identifiable. In federated settings, however, each client observes only a limited and fragmentary view of user behavior, rendering such point estimates inherently brittle. To address this mismatch, we model user preferences as distributions rather than points, allowing multiple compatible preference representations to coexist. Rather than collapsing evidence into a single embedding, our approach preserves uncertainty and diversity in user representations, providing a richer basis for preference modeling. We instantiate this idea with a diffusion-based generative framework that produces diverse user embeddings and derives recommendation scores by aggregating predictions across them. This distributional formulation yields more stable ranking behavior and improved robustness under ambiguous feedback. Extensive experiments on federated recommendation benchmark datasets demonstrate consistent and significant improvements over baselines. Our code is available.

LittleBit-2: Maximizing the Spectral Energy Gain in Sub-1-Bit LLMs via Latent Geometry Alignment
Banseok Lee, Youngmin Kim
We identify the Spectral Energy Gain in extreme model compression, where low-rank binary approximations outperform tiny-rank floating-point baselines for heavy-tailed spectra. However, prior attempts fail to realize this potential, trailing state-of-the-art 1-bit methods. We attribute this degradation to Latent Geometr

y Misalignment: standard singular vectors exhibit high coherence (spiky distribu
tion), the worst-case geometry for binary quantization. To realize this gain, we
 propose LittleBit-2, a framework employing Internal Latent Rotation and Joint I
terative Quantization (Joint-ITQ). This approach acts as a geometric preconditio
ner, aligning coherent latent distributions with the binary hypercube with zero
 inference overhead. Empirically, LittleBit-2 establishes a new state-of-the-art
 in the sub-1-bit regime (1$\sim$0.1 bpp) on Llama-2 and Llama-3, matching the fi
delity of leading 1-bit baselines.

Differentiable Optimization Layers for Guaranteed Fairness in Deep Learning
David Troxell, Noah Roemer, Guido Montufar
Differentiable optimization layers are traditionally integrated in predict-then-
optimize frameworks where a neural model estimates parameters that subsequently
 serve as fixed inputs to downstream decision-making optimization problems. In th
is work, we introduce the concept of a "fairness layer": a differentiable optimi
zation layer appended to a model's output layer that guarantees a chosen notion
 of output parity is satisfied when integrated into a neural network. Additionall
y, we introduce an online primal-dual inference algorithm that provides provable
 aggregate fairness guarantees for streaming predictions with arbitrarily small
 batch sizes, where traditional per-batch constraints become overly restrictive.
 Numerical experiments demonstrate the effectiveness of the fairness layer and as
sociated algorithm, and theoretical analysis characterizes the layer's different
iability and stability properties during model training and backpropagation. Our
 code for these experiments is publicly available on GitHub: https://github.com/
dtroxell19/FairDL-ICML-2026.git and our public Python package documentation can
 be found online: https://dtroxell19.github.io/fairness_training/.

S^{3}GNN: Efficient Global Mixing and Local Message Passing for Long-Range Graph
 Learning
Dai Shi, Luke Thompson, Linhan Luo, Lequan Lin, Andi Han, Junbin Gao, José Migue
l Hernández-Lobato
Message-passing neural networks (MPNNs) often suffer from an information bottlen
eck when capturing long-range dependencies, leading to the oversquashing (OSQ) p
henomenon. Alongside spatial connectivity enrichment (e.g., rewiring), recent st
udies have shown that spectral filtering can yield strong long-range learning ou
tcomes, as spectral operators enable global information mixing that alleviates O
SQ. These approaches achieve this either by stabilizing the Jacobian energies in
 deep propagation or by guaranteeing OSQ mitigation under strong theoretical ass
umptions. We examine the practical attainability of these guarantees and show th
at the associated Jacobian sensitivity lower bound is generally difficult to ach
ieve in practice. We then propose S^{3}GNN, which mitigates OSQ without such res
trictive assumptions by lightweightly reintroducing omitted components with subs
tantially lower computational complexity, while standard stability constraints o
n feature transformations remain effective under our new dynamics. Extensive exp
eriments across diverse domains (e.g., long-range benchmarks, KGQA, and mesh-bas
ed fluid dynamics) demonstrate that S^{3}GNN achieves up to an order-of-magnitud
e error reduction with up to 50\% fewer parameters. Our code can be found in htt
ps://github.com/EEthanShi/S3-GNN.git.

SE-GA: Memory-Augmented Self-Evolution for GUI Agents
Shilong Jin, Lanjun Wang, Zhuosheng Zhang
Autonomous Graphical User Interface (GUI) agents often struggle with multi-step
 tasks due to constrained context windows and static policies that fail to adapt
 to dynamic environments. To address these limitations, this work proposes the Se
lf-Evolving GUI Agent (SE-GA), a novel framework that integrates hierarchical me
mory structures with an iterative self-improvement mechanism. At the core of ou
r approach is Test-Time Memory Extension (TTME), which facilitates long-term pla
nning by dynamically retrieving episodic, semantic, and experiential memories to
 provide salient contexts during inference. To ensure continuous learning, we in
troduce Memory-Augmented Self-Evolution (MASE), which is a training pipeline tha

t adopts the data collected by TTME to stabilize and enhance the agent's foundat ional policy. Extensive evaluations across both offline and online benchmarks de monstrate SE-GA achieves state-of-the-art performance, reaching success rates of 89.0\% on ScreenSpot and 75.8\% on the challenging AndroidControl-High dataset. Furthermore, significant improvements on the AndroidWorld benchmark highlight t he superior generalization to dynamic environments.

Correspondence Cognitive Learning for Multi-Modal Object Re-Identification

Chao Su, Shuying Li, Ruitao Pu, Dezhong Peng, Zhenwen Ren, Yuan Sun

Multi-modal object Re-Identification (ReID) aims to retrieve the same object acr oss different modalities by exploiting their complementary visual information. R ecent advances leverage Multi-modal Large Language Models (MLLMs) to generate de scriptive textual annotations as auxiliary supervision. However, existing approa ches usually adopt these generated texts directly, overlooking the varying corre spondence degrees between visual and textual modalities. Such neglect may lead t he model to treat strong- and weak-correspondence image–text pairs equally, limi ting its ability to learn discriminative associations and hindering effective op timization. To overcome this limitation, we propose a Correspondence Cognitive L earning (CCL) framework that explicitly models the correspondence degree and fac ilitates a progressive learning process from easy to hard pairs. CCL is composed of two synergistic modules. The Correspondence-Guided Semantic Refinement (CGSR) module dynamically refines visual representations using text semantics accordi ng to the correspondence difficulty estimated from the previous epoch, thereby e nhancing feature alignment under imperfect associations. The Cognitive-Driven Dy namic Optimization (CDDO) module presents a self-paced weighting mechanism that adaptively adjusts the optimization focus by emphasizing easy pairs at the early stage and gradually integrating harder ones as training evolves. Together, thes e modules enhance feature-level alignment and optimization adaptivity, yielding robust and discriminative multi-modal representations. Extensive experiments on three multi-modal object ReID benchmarks demonstrate the superior performance of our method.

Spherical Steering: Geometry-Aware Activation Rotation for Language Models

Zejia You, Chunyuan Deng, Hanjie Chen

Inference-time steering offers a promising way to control language models (LMs) without retraining. However, standard approaches typically rely on activation ad dition, which inevitably alters the hidden-state magnitudes raising concerns abo ut representation collapse and degraded open-ended generation. In this work, we explore *Spherical Steering*, a training-free primitive that resolves this trade -off through activation rotation. Rather than shifting activations with a fixed vector, our method rotates them along a geodesic toward a target direction, pres erving signal integrity while steering toward the target concept. To further enh ance adaptivity, we incorporate a confidence gate that dynamically modulates ste ering strength based on input uncertainty. Extensive experiments across multiple -choice benchmarks demonstrate that Spherical Steering significantly outperforms addition-based baselines (notably by +10\% on TruthfulQA, COPA, and Storycloze) , while simultaneously maintaining the model’s general open-ended generation qua lity. This work highlights the value of geometric consistency, suggesting that n orm-preserving rotation is a robust and effective primitive for precise inferenc e-time control. The code is available at: https://github.com/chili-lab/Spherical -Steering.

Reliable Thinking with Images

Haobin Li, Yutong Yang, Yijie Lin, Xiang Dai, Mouxing Yang, Xi Peng

As a multimodal extension of Chain-of-Thought (CoT), Thinking with Images (TWI) has emerged as a promising avenue to enhance the reasoning capability of Multi-m odal Large Language Models (MLLMs), which generates interleaved CoT by incorpora ting visual cues into the textual reasoning process. However, the success of exi sting TWI methods heavily relies on the assumption that interleaved CoTs are fau ltless, which is easily violated due to the complexity of multimodal understandi

ng. In this paper, we reveal and study a highly-practical yet under-explored pro blem in TWI, termed Noisy Thinking (NT). Specifically, NT refers to the imperfec t visual cues mining and answer reasoning process. As the saying goes, ``One mis take leads to another'', erroneous interleaved CoT would cause error accumulatio n, thus significantly degrading the performance. To solve NT, we propose a novel method dubbed Reliable Thinking with Images (RTWI). In brief, RTWI estimates th e reliability of visual cues and textual CoT in a unified text-centric manner an d then employs robust filtering and voting modules to prevent NT from contaminat ing final answer. Extensive experiments on seven benchmarks verify the effective ness of RTWI against NT.

GOCM: Single-Step Graph Outlier Synthesis via Origin Consistency Model
Yifan Li, Zhihui Wang, Changmiao Wang, Guangxiao Ma, Peng Zhang
Supervised Graph Outlier Detection has long been constrained by severe class imb alance, and although recent diffusion-based augmentation methods have improved s ample quality, their practical utility is hindered by the high computational cos ts of multi-step iterative sampling and the stochasticity of the generation proc ess. To overcome these bottlenecks, we propose Graph Outlier Synthesis via Origi n Consistency Model (GOCM), a single-step graph outlier synthesis framework base d on a consistency model. Theoretically, we pioneer the Origin Consistency (OC) mechanism by employing an ``Interval-based Origin Inference'' strategy, which ma thematically derives a direct mapping from the noise trajectory to the data orig in, achieving robust and efficient single-step sample generation. Architecturall y, to address the complexity of heterogeneous graphs containing multiple relatio ns, we design the Multi-input Variational Graph Auto-Encoder (MiVGAE), which dec ouples intricate structures via relation-level message passing and cross-relatio n fusion, mapping them into a unified latent space, from which GOCM synthesizes high-quality outlier nodes. Extensive experiments on multiple real-world dataset s demonstrate that GOCM achieves superior detection performance with significant ly improved generation efficiency. The source code is publicly available at: htt ps://anonymous.4open.science/r/RFS-2026-EB63/.

PhenoBrain: Phenotype-Conditioned Long-Range Communication for Multi-Modal Brain Network Analysis
Lingyuan Meng, KE LIANG, Hao Li, Meng Liu, Weijia Shi, Miaomiao Li, Yang Gao, Xi nwang Liu
Multi-modal brain network analysis aims to predict neuropsychiatric status from functional connectomes with heterogeneous phenotypes. However, most existing met hods treat phenotypes as auxiliary features and perform late fusion, implicitly assuming that the connectome representation should be learned in the same way re gardless of phenotype. However, in clinical neuroscience the same functional con nectivity pattern may support different conclusions under different phenotype co ntexts. To bridge this gap, we propose PhenoBrain, a novel framework for multi-m odal brain network analysis that injects phenotype information at the mechanism level rather than only at the classifier level. Specifically, we propose a pheno type-conditioned long-range routing mechanism, which learns a subject-specific m ulti-hop communication kernel to model long-range connectome interactions. Furth ermore, we propose a phenotypic-guided attention mechanism regulation method, wh ich uses phenotypic information as a conditional prior to regulate the learning process of attention in brain networks. To verify the effectiveness of our metho d, we constructed two multi-modal brain network analysis datasets based on open-source image data. Extensive experiments demonstrate that PhenoBrain achieves st ate-of-the-art performance.

Adversarial Attacks and Robust Training for Hypergraph Neural Networks
Naheed Anjum Arafat, Debabrota Basu, Yulia Gel, Danda B. Rawat
Recent studies show that Hypergraph Neural Networks (HGNNs) are vulnerable to ad versarial attacks, while adversarial learning in the context of hypergraphs rema ins substantially under-investigated. In particular, all existing attacks on HGN Ns are white-box and customized for either structural or feature perturbation. B

ut in reality, the attacker might not have access to the target model parameters . Motivated by this knowledge gap, we propose a generic meta-objective-based lea rning framework, MeLA, that leverages the hypergraph Laplacian to conduct gray-b ox, structural, and feature perturbations under explicit perturbation budgets. I n contrast to the attack literature, there is no adversarial training mechanism for HGNNs to defend against such attacks. Hence, we propose a novel adversarial training mechanism for HGNNs to obtain a robust classifier. We further prove the convergence of our robust training. Extensive experiments across various HGNN m odels and datasets show that (a) our proposed attack is effective in poisoning a nd evasion settings, and (b) our adversarial training enhances defense against a dversarial attacks.

New Bounds for Kernel Sums via Fast Spherical Embeddings
Tal Wagner
We study query time bounds for the fundamental problem of estimating the kernel mean $\frac1{|X|}\sum_{x\in X}\mathbf{\mathrm{k}}(x,y)$ of a query y in a fini te dataset $X\subset\mathbb{R}^d$ up to a prescribed additive error $\varepsilon $. The best known bounds for the Gaussian kernel are $O(d/\varepsilon^2)$, $\wid etilde O(d+1/\varepsilon^4)$, and $\widetilde O(d+\Delta^2/\varepsilon^2)$, wher e Δ is the diameter of a region containing the points. We prove the new b ound $\tilde O(d+\varepsilon\Delta^2+1/\varepsilon^3)$, which improves over the previous ones in regimes with small error ε and intermediate diamete r Δ.

At the center of our proof is a new fast spherical embedding theorem in the sens e introduced by Bartal, Recht and Schulman (2011), which limits the embedded dat a diameter while preserving local Euclidean distances and avoiding ``distance co llapse'' at larger scales. This fast embedding theorem may be of independent int erest.

Bounded Hyperbolic Tangent: A Stable and Efficient Alternative to Pre-Layer Norm alization in Large Language Models
Hoyoon Byun, Youngjun Choi, Taero Kim, Sungrae Park, Kyungwoo Song
Pre-Layer Normalization (Pre-LN) is the de facto choice for large language model s (LLMs) and is crucial for stable pretraining and effective transfer learning. However, Pre-LN incurs repeated statistical-computation overhead and remains vul nerable to the curse of depth, where hidden-state magnitudes and variances grow as the number of layers increases, destabilizing training. Efficiency-oriented n ormalization-free methods such as Dynamic Tanh (DyT) improve throughput but rema in fragile at depth. To jointly address stability and efficiency, we propose Bou nded Hyperbolic Tanh (BHyT), a drop-in replacement for Pre-LN. BHyT combines a t anh nonlinearity with explicit, data-driven input bounding to keep activations w ithin a non-saturating range. It prevents depth-wise growth in activation magnit ude and variance and provides a theoretical stability guarantee. For efficiency, BHyT computes exact statistics once per block and replaces a second normalizati on with a lightweight variance approximation. Empirically, BHyT demonstrates imp roved stability and efficiency during pretraining, achieving an average of 1.6\% faster training and an average of 1.77\% higher token generation throughput com pared to RMSNorm, while maintaining strong pretraining-only and post-SFT perform ance across language understanding and reasoning benchmarks\footnote{Code is ava ilable at: \url{https://github.com/MLAI-Yonsei/BHyT}}.

Less Is More: Elevating RAG via Performance-Driven Context Compression
Ziqiang Cui, Yunpeng Weng, Xing Tang, Peiyang Liu, Shiwei Li, Bowei He, Jiamin C hen, Yansen Zhang, Xiuqiang He, Rui Zhang, Chen Ma
Retrieval-Augmented Generation (RAG) has emerged as a promising paradigm for imp roving the timeliness of knowledge updates and the factual accuracy of large lan guage models. However, incorporating a large volume of retrieved documents signi ficantly increases input length, leading to prohibitive computational costs. Exi sting compression approaches often compromise task performance, primarily due to

their reliance on predefined heuristics. These heuristics fail to ensure that the compressed context is conducive to the generation tasks. To address these limitations, we propose CORE-RAG, a novel framework for context compression in RAG systems.
CORE eliminates reliance on proxy heuristics through a performance-driven learning framework, which directy utilizes task performance as a feedback signal to iteratively refine the compressor policy. Prior to this optimization process, we incorporate a knowledge distillation phase to initialize the compressor with a robust policy. Extensive experiments demonstrate the superiority of our approach. At a high compression ratio of 3\%, CORE not only avoids performance degradation but also improves the average Exact Match (EM) score by 3.3 points compared to using full documents. Our code is available at https://github.com/ziqiangcui/CORE-RAG-ICML26.

Data Reconstruction: Identifiability and Optimization with Sample Splitting
Yujie Shen, Zihan Wang, Jian Qian, Qi Lei
Training data reconstruction from KKT conditions has shown striking empirical success, yet it remains unclear when the resulting KKT equations have unique solutions and, even in identifiable regimes, how to reliably recover solutions by optimization. This work hereby focuses on these two complementary questions: identifiability and optimization. On the identifiability side, we discuss the sufficient conditions for KKT system of two-layer networks with polynomial activations to uniquely determine the training data, providing a theoretical explanation of when and why reconstruction is possible. On the optimization side, we introduce sample splitting, a curvature-aware refinement step applicable to general reconstruction objectives (not limited to KKT-based formulations): it creates additional descent directions to escape poor stationary points and refine solutions. Experiments demonstrate that augmenting several existing reconstruction methods with sample splitting consistently improves reconstruction performance. Code is available at https://github.com/mukerr/data_recon.

Correcting in Hindsight: Editing Past Key-Value States for Robust LLM Reasoning
Mengfei Zhang, Yu Mi, Leijing Zhou
Autoregressive Large Language Models (LLMs) often fail in complex reasoning because early-stage errors remain uncorrectable in subsequent steps—a limitation fundamentally rooted in the inherent irreversibility of the Transformer architecture. In this paper, we propose HEdit, a lightweight reasoning enhancement paradigm that equips models with a "hindsight-like" capability for dynamic error correction during generation. Our core insight involves deconstructing reasoning failures into two pivotal stages: latent representational biases emerging at logical anchors, and the subsequent eruption of explicit cognitive dissonance at trigger points. Based on these observations, the HEdit framework detects internal inconsistency signals at trigger points in real-time, actively backtracks to critical anchors, and utilizes a lightweight trainable editor to precisely refine their Key-Value (KV) caches. This mechanism effectively breaks the unidirectional constraints of autoregressive inference. Empirical results demonstrate that HEdit significantly enhances the performance of various models on mathematical reasoning tasks—with average accuracy improvements ranging from 2.2\% to 10.8\%—while maintaining extremely low overhead (add parameters $<0.5\%$). HEdit provides a dynamic, pluggable and lightweight solution, making it particularly beneficial for users in low-resource environments.

Maximin Relative Improvement: Fair Learning as a Bargaining Problem
Jiwoo Han, Moulinath Banerjee, Yuekai Sun
When deploying a single predictor across multiple subpopulations, we propose a fundamentally different approach: interpreting group fairness as a bargaining problem among subpopulations. This game-theoretic perspective reveals that existing robust optimization methods such as minimizing worst-group loss or regret correspond to classical bargaining solutions and embody different fairness principles

. We propose relative improvement, the ratio of actual risk reduction to potenti
al reduction from a baseline predictor, which recovers the Kalai–Smorodinsky sol
ution. Unlike absolute-scale methods that may not be comparable when groups have
 different potential predictability, relative improvement provides axiomatic jus
tification including scale invariance and individual monotonicity. We establish
 finite-sample convergence guarantees under mild conditions.

Thinking in Flow: A Dissipative Stabilization Operator for Robust Autoregressive
 Reasoning

Yujie Huang, Wenwu He, Zhuo-Xu Cui

Chain-of-Thought (CoT) prompting enables multi-step reasoning in large language
 models, yet long-horizon generation remains brittle under distribution shift and
 context interference: irrelevant cues persist, small deviations compound into i
nference drift, and late-stage corrections can destabilize the trajectory. We re
cast autoregressive decoding as a perturbed long-horizon dynamical system and in
troduce an *inference-time stabilization operator* that targets *trajectory-leve
l* reliability rather than token-level fluency. Specifically, we propose *ODE-gu
ided language models*, which augment a base Transformer with a persistent contin
uous-time *thought state* whose dynamics are explicitly designed to be dissipati
ve, enabling stable evidence accumulation with controlled forgetting. Instantiat
ing this framework, *Thinking in Flow* (TiF) equips the model with a lightweight
 Neural ODE controller and injects its output through post-norm residual updates
 to achieve numerically stable, low-intrusion steering. A demand--supply (uncert
ainty--capacity) gate determines *when* intervention is warranted, while a direc
tion gate determines *how* to steer in representation space, yielding selective,
 do-no-harm corrections instead of persistent bias. We establish well-posedness,
 dissipativity, and incremental stability of the controlled thought dynamics, im
plying bounded interventions over arbitrarily long contexts, and empirically dem
onstrate improved robustness to distractions and semantic perturbations, while m
atching or improving accuracy on mathematical reasoning benchmarks across both t
he Llama and Qwen model families; we further observe gains on non-mathematical B
BH reasoning tasks when training TiF on Llama.

Think in Cloud, Look at Edges: Semantic-Driven Query Decomposition for Efficient
 Video Reasoning

Wenhao Zou, Zhijie Cai, Minchen Yu, Zongshuai Zhang, Guangxu Zhu

Long video understanding faces a critical dilemma: cloud-based Large Multimodal
Models (LMMs) offer superior reasoning but suffer from prohibitive bandwidth cos
ts and latency, while edge-based solutions sacrifice perception accuracy for spe
ed. Current collaborative approaches attempt to bridge this gap via similarity-b
ased filtering, yet they treat complex queries as flat semantic vectors. We iden
tify this as a fundamental flaw leading to "Semantic Submergence," where dominan
t visual features drown out subtle but logically critical cues. To solve this, w
e introduce SCOPE (Semantic Cloud-Orchestrated Perception at Edge). Shifting the
 paradigm to "Think in Cloud, Look at Edges," SCOPE utilizes a cloud LMM to deco
mpose complex queries into a structured Directed Acyclic Graph (DAG). This "obse
rvation plan" guides the edge to retrieve evidence based on logical necessity ra
ther than mere statistical similarity. Experiments on Video-MME and LongVideoBen
ch demonstrate that SCOPE redefines the Pareto frontier, matching cloud-level ac
curacy with significantly lower transmission costs and outperforming state-of-th
e-art baselines on complex reasoning tasks.

Predictable Compression Failures: Order Sensitivity and Information Budgeting fo
r Evidence-Grounded Binary Adjudication

Leon Chlon, Ahmed Karim, MarcAntonio Awada

Transformers used for evidence-grounded binary adjudication (e.g., support/refut
e, yes/no, or verifier-backed pass/fail decisions) can be sensitive to the order
 in which exchangeable evidence is presented, producing dispersion across permut
ations and unreliable attempted answers under a verifier-relative Bernoulli pred
icate. We treat evidence order as a nuisance variable and formalize an expectati

on–realization gap: next-token training can minimize expected conditional descri ption length over orderings while a fixed ordering remains position-sensitive. O ur Quantified Martingale Violation (QMV) bound predicts the dispersion induced b y adjacent-rank positional sensitivity, with $O(\log n)$ growth in the harmonic regime; our Expectation-level Decompression Law (EDFL) specializes a KL convexit y/data-processing bound to Bernoulli predicates, yielding Bits-to-Trust (B2T), R isk-of-Hallucination (RoH), and an Information Sufficiency Ratio (ISR) gate for answer/abstain decisions. On 3,059 grounded items from FEVER, HotpotQA, NQ-Open, PopQA, and Controls, we observe logarithmic dispersion and positive Jensen gain s from uniform permutation mixtures. In one pre-specified held-out audit (528 it ems), the analytically fixed $ISR=1$ gate attains 0.0–0.7% hallucination with 20 .6–27.9% abstention (95% CIs), supporting the operating point without claiming u niversal calibration across all model families or unrestricted generation.

Contextualized Visual Personalization in Vision-Language Models
Yeongtak Oh, Sangwon Yu, Junsung Park, Han Cheol Moon, Jisoo Mok, Sungroh Yoon
Despite recent progress in vision-language models (VLMs), existing approaches of ten fail to generate personalized responses based on the user's specific experie nces, as they lack the ability to associate visual inputs with a user’s accumula ted visual-textual context. We newly formalize this challenge as contextualized visual personalization, which requires the visual recognition and textual retrie val of personalized visual experiences by VLMs when interpreting new images. To address this issue, we propose CoViP, a unified framework that treats personaliz ed image captioning as a core task for contextualized visual personalization and improves this capability through reinforcement-learning-based post-training and caption-augmented generation. We further introduce diagnostic evaluations that explicitly rule out textual shortcut solutions and verify whether VLMs truly lev erage visual context. Extensive experiments demonstrate that existing open-sourc e and proprietary VLMs exhibit substantial limitations, while CoViP not only imp roves personalized image captioning but also yields holistic gains across downst ream personalization tasks. These results highlight CoViP as a crucial stage for enabling robust and generalizable contextualized visual personalization.

On the Convergence Rate of LoRA Gradient Descent
Siqiao Mu, Diego Klabjan
The low-rank adaptation (LoRA) algorithm for fine-tuning large models has grown popular in recent years due to its remarkable performance and low computational requirements. LoRA trains two "adapter" matrices that form a low-rank representa tion of the model parameters, thereby massively reducing the number of parameter s that need to be updated at every step. Although LoRA is simple, its convergenc e is poorly understood due to the lack of Lipschitz smoothness, a key condition for classic convergence analyses. As a result, current theoretical results only consider asymptotic behavior or assume strong boundedness conditions which artif icially enforce Lipschitz smoothness. In this work, we provide for the first tim e a non-asymptotic convergence analysis of the *original LoRA gradient descent* algorithm, which reflects widespread practice, without such assumptions. Our wor k relies on three key steps: i) reformulating the problem in terms of the outer product of the stacked adapter matrices, ii) a modified descent lemma for the "L ipschitz-like" reparametrized function, and iii) controlling the step size. With this approach, we prove that LoRA gradient descent converges to a stationary po int at rate $O(\frac{1}{\log T})$, where T is the number of iterations.

Marrying Generative Model of Healthcare Events with Digital Twin of Social Deter minants of Health for Disease Reasoning
Ziquan Wei, Tingting Dan, Guorong Wu
Despite the central role of sensor-derived measurements such as imaging traits a nd plasma biomarkers in biomedical research and clinical practice, existing gene rative models for disease prediction largely depend on event-level representatio ns from hospital and registry data. Given the multi-factorial nature of human di sease, the absence of explicit modeling of social determinants of health (SDoH)

limits the capacity for personalized disease modeling and clinical decision support.
To address this limitation, we propose a generative model with ICD-coded proxies of SDoH for \textit{in silico} modeling of disease reasoning, a conditioned latent diffusion framework that establishes the connection between multi-organ sensor data with tokenized healthcare events. Specifically, we introduce a novel geometric diffusion model to characterize the temporal evolution of complex data representation such as brain networks (region-to-region connectivity encoded in a graph), in parallel with diffusion models for tabular data from other organ systems.
Together, we integrate the generative model with digitalized SDoH proxies (coined **DiffDT**) for simulated intervention and reasoning of future disease trajectories.
We conduct extensive experiments on the UK Biobank (UKB) dataset, which contains organ-specific imaging traits, including brain (44,834), heart (23,987), liver (28,722), and kidney (32,155), along with nearly 500k medical history sequences (age range: 25$\sim$89 years). Our **DiffDT** achieves significant improvements over state-of-the-art human disease autoregressive models and imaging trait generative baselines.
****

When and How Human Curation Backfires: Preference Alignment under Multi-Model Self-Consuming Loop
Yang Zhang, Xiukun Wei, Xueru Zhang
Foundation models are increasingly trained on synthetic data generated by prior model iterations rather than exclusively on real data. This *self-consuming* training paradigm can lead to model collapse, divergence, or bias amplification. Recent work (Ferbach et al., 2024) shows that incorporating human curation into the loop can steer a self-consuming model toward human-aligned behavior, but these analyses focus on a single, isolated model that solely consumes its own outputs. In practice, however, models often interact and train on input output pairs produced by other models. This paper studies self-consuming training in the *multi-model* regime. We first formalize a framework for interacting self-consuming models and characterize when the resulting dynamical system converges to a stable point. We then examine how human curation of one model affects its own alignment (self-influence) and how such effects propagate to other models (cross-influence). Unlike isolated settings where human curation always enhances model alignment, we show that cross-model interactions can dampen or even invert this effect, ultimately degrading long-term alignment.

BAT: Better Audio Transformer Guided by Convex Gated Probing
Houtan Ghaffari, Lukas Rauch, Christoph Scholz, Paul Devos
Probing is widely adopted in computer vision to faithfully evaluate self-supervised learning (SSL) embeddings, as finetuning may misrepresent their inherent quality. In contrast, audio SSL models still rely on finetuning because simple probing fails to unlock their full potential and alters their rankings when competing on AudioSet. Hence, a robust and efficient probing mechanism is required to guide the trajectory of audio SSL towards reliable and reproducible methods. We introduce *Convex Gated Probing* (CGP), a prototype-based method that significantly closes the gap between finetuning and probing in audio. CGP efficiently utilizes all frozen layers via a gating mechanism and exposes the location of latent task-relevant information. Guided by CGP as a reliable post-hoc evaluation probe, we rework the entire SSL pipeline of current best performing audio models that use legacy implementations of prior SSL methods. By refining data preprocessing, model architecture, and pretraining recipe, we introduce *Better Audio Transformer* (BAT), and establish new SOTA on audio benchmarks.

Beyond Drift: Stabilizing Subjective LLM Evaluation with Information-Theoretic Rubrics
Wang Xu, Shan Zhao, Haolan Chen, Tianwei Yan, Chengyu Wang, Shizhao Chen, Qian Wan

Despite the growing use of large language models (LLMs) in subjective tasks such as role-playing, humor, emotional intelligence, and dialogue quality, their evaluation faces a pressing reproducibility crisis: even the same evaluator may contradict itself when re-judging the exact same sample.
We attribute this instability to dimension drift, where free-form evaluation protocols (e.g., Chain-of-Thought reasoning) unpredictably shift their implicit criteria, undermining reliability.
To address this fundamental challenge, we reformulate subjective evaluation as an information-theoretic optimization problem. Specifically, we propose an **Expected Information Gain (EIG)-based framework** that constructs a stable yet adaptive personalized rubric to eliminate dimension drift.
Our two-stage “generate–then–score” design first produces a diverse pool of candidate evaluation questions and then selects the most informative subset via EIG, yielding explicit and repeatable criteria.
Experiments on six benchmarks, including CharacterEval, The rJokes, and MT_bench, demonstrate that our approach substantially improves both evaluation consistency and alignment with human judgments, outperforming CoT-based and fixed-questionnaire baselines.
These results highlight that information-theoretic questionnaire construction offers a principled and reliable path toward reproducible evaluation of subjective tasks.

Training-Free Multimodal Large Language Model Orchestration
Tianyu Xie, Yuexiao Ma, Yuhang Wu, Wang Chen, Jiayi Ji, Tat-Seng Chua, Xiawu Zheng, Rongrong Ji
Building interactive omni-modal assistants often relies on end-to-end multimodal alignment to fuse heterogeneous modalities, which incurs substantial data and compute costs and limits extensibility. We present Training-Free Large Language Model Orchestration (LLM Orchestration), a training-free orchestration framework that integrates off-the-shelf modality experts into a unified multimodal input--output system without additional gradient-based training for integration. LLM Orchestration comprises three components: (1) an LLM controller that infers user intent and emits explicit control tokens for expert selection and sequencing, enabling protocol-constrained and auditable routing; (2) a text-centric cross-modal memory that compresses multimodal evidence into structured records for lightweight retrieval and reuse, reducing redundant expert invocations across turns; and (3) a unified interaction layer that executes routing and memory decisions to support consistent modality transitions, full-duplex streaming, and interruption-aware dialogue. Across diverse multimodal benchmarks, LLM Orchestration achieves strong performance under standard evaluation constraints while maintaining low orchestration overhead and modular upgradeability, providing a practical alternative to costly joint training for omni-modal systems.

SelfJudge: Faster Speculative Decoding via Self-Supervised Judge Verification
Kanghoon Yoon, Minsub Kim, Sungjae Lee, Joonhyung Lee, Sunghyeon Woo, Yeonjun In, Se Jung Kwon, Chanyoung Park, Dongsoo Lee
Speculative decoding accelerates LLM inference by verifying candidate tokens from a draft model against a larger target model. Recent "judge'' decoding boosts this process by relaxing verification criteria by accepting draft tokens that may exhibit minor discrepancies from target model output, but existing methods are restricted by their reliance on human annotations or tasks with verifiable ground truths, limiting generalizability across diverse NLP tasks. We propose SelfJudge, which trains judge verifiers via self-supervision of the target model. Our method measures semantic preservation by assessing whether token-substituted responses preserve the meaning of original responses, enabling automatic verifier training across diverse NLP tasks. Our experiments show SelfJudge achieves superior inference-accuracy trade-offs than judge decoding baselines, offering a broadly applicable solution for faster LLM inference.

Certificate-Guided Pruning for Stochastic Lipschitz Optimization

Ibne Farabi Shihab, Sanjeda Akter, Anuj Sharma
We study black-box optimization of Lipschitz functions under noisy evaluations. Existing adaptive discretization methods implicitly avoid suboptimal regions but do not provide explicit certificates of optimality or measurable progress guarantees. We introduce **Certificate-Guided Pruning (CGP)**, which maintains an explicit *active set* A_t of potentially optimal points via confidence-adjusted Lipschitz envelopes. Any point outside A_t is certifiably suboptimal with high probability, and under a margin condition with near-optimality dimension α, we prove Vol(A_t) shrinks at a controlled rate yielding sample complexity $Õ(\varepsilon^{-(2+\alpha)})$. We develop three extensions: CGP-Adaptive learns L online with $O(\log T)$ overhead; CGP-TR scales to $d > 50$ via trust regions with local certificates; and CGP-Hybrid switches to GP refinement when local smoothness is detected. Experiments on 12 benchmarks ($d \in [2, 100]$) show CGP variants match or exceed strong baselines while providing principled stopping criteria via the computable gap proxy ε_t.
****
EduMirror: Modeling Educational Social Dynamics with Value-driven Multi-agent Simulation
Jingzhe Lin, Hengbin Yu, Yongdan Zeng, Fangwei Zhong
Understanding how educational social dynamics evolve is critical for informing effective educational policies and counterfactual interventions. However, traditional methods face a fundamental dilemma: observational studies often lack causal power, while controlled experiments are frequently constrained by ethical concerns. Although LLM-based multi-agent simulations offer a scalable **in silico** alternative, existing approaches remain limited by weak psychological grounding and insufficient measurement of latent psychological states. To address this, we introduce **EduMirror**, a multi-agent simulator for the scientific study of educational social dynamics. We provide configurable education-oriented agent forms, including value-driven agents grounded in psychological needs and social value orientation, together with a dual-track measurement protocol for quantifying observable behaviors and latent psychological states. We validate the realism and usability of EduMirror through case studies on school bullying and group cooperation, as well as broader evaluations across diverse educational scenarios. The results show that EduMirror generates educational social dynamics that are realistic, theory-consistent, and measurable by empirical criteria. These properties enable structured **in silico** educational research, providing a computational tool for hypothesis testing and counterfactual intervention analysis in educational science. Project page: *https://edumirror.net*.

Select to Think: Unlocking SLM Potential with Local Sufficiency
Wenxuan Ye, Yangyang Zhang, Xueli An, Georg Carle, Yunpu Ma
Small language models (SLMs) offer efficient deployment, yet they often lag behind their larger counterparts (LLMs) in reasoning.
Existing remedies either invoke an LLM at points of reasoning divergence, incurring substantial latency and cost, or rely on standard distillation, which is limited by the SLM's capacity to accurately mimic the LLM's complex generative distribution.
We address this dilemma by identifying local sufficiency: at divergence points, the LLM's preferred token often resides within the SLM's top-K next-token predictions, even when failing to emerge as the SLM top-1 choice.
We therefore propose Select to Think (S2T), which reframes the LLM’s role from open-ended generation to selection among the SLM's proposals, simplifying the supervision signal to discrete candidate rankings.
Leveraging this, we introduce S2T-Local, which distills the selection logic into the SLM, empowering it to perform autonomous re-ranking without inference-time LLM dependency.
Empirically, a 1.5B SLM's top-8 candidates contain the 32B LLM's choice with a 95\% hit rate, and S2T-Local improves the 1.5B SLM's Math Avg. over greedy decoding by 24.1\% relative gain, matching the efficacy of 8-path self-consistency with single-trajectory efficiency.

Code is available at https://github.com/YeRona/Select-to-Think.

MiVE: Multiscale Vision-language features for reference-guided video Editing
Tong Wang, Meng Zou, WU CHENGJING, Xiaochao Qu, Luoqi Liu, Xiaolin Hu, Ting Liu
Reference-guided video editing takes a source video, a text instruction, and a reference image as inputs, requiring the model to faithfully apply the instructed edits while preserving original motion and unedited content. Existing methods fall into two paradigms, each with inherent limitations: decoupled encoders suffer from modality gaps when processing instructions and visual content independently, while unified vision-language encoders lose fine-grained spatial details by relying solely on final-layer representations. We observe that VLM layers encode complementary information hierarchically—early layers capture localized spatial details essential for precise editing, while deeper layers encode global semantics for instruction comprehension. Building on this insight, we present \textbf{MiVE} (\textbf{M}ult\textbf{i}scale \textbf{V}ision-language features for reference-guided video \textbf{E}diting), a framework that repurposes VLMs as multiscale feature extractors. MiVE extracts hierarchical features from Qwen3-VL and integrates them into a unified self-attention Diffusion Transformer, eliminating the modality mismatch inherent in cross-attention designs. Experiments demonstrate that MiVE achieves state-of-the-art performance by ranking highest in human preference, outperforming both academic methods and commercial systems.

Statistically Calibrated Scaling for Token Merging in Transformers
Qing Zhou, Hongyuan Zhang, Tao Yang, Junyu Gao, Qi Wang
Token merging accelerates Transformer inference by clustering similar tokens to reduce sequence length (retention ratio r), but distorts attention outputs, inducing covariate shift in residual streams and performance collapse under high compression. Existing heuristics, such as proportional attention, mitigate mild compression effectively but degrade sharply at aggressive ratios due to unaddressed energy drift and biased attention distributions.

We reframe token merging as a statistical reconstruction problem in high dimensions and introduce an asymptotic radial-angular decomposition of the reconstruction error, an analytical framework decoupling magnitude and distributional distortions. Minimizing this decomposed risk under minimal assumptions of finite second moments and variance stationarity yields closed-form optimal corrections governed by a single scaling factor $\sqrt{r}$: scaling merged values and shrinking merged logits toward the cluster-size prior. This calibrates both energy balance and distributional fidelity. Extensive experiments on vision Transformers demonstrate superior accuracy and robustness across compression levels.
****
CACR: Reinforcing Temporal Answer Grounding in Instructional Video via Candidate-Aware Causal Reasoning
Muge Qi, Rong Fu, Pengbin Feng, Xianda Li, Yu Cai, Yifu Guo, Shizhe Zhang, Simon James Fong, Lei Ma, Bin Li
The task of temporal answer grounding in instructional videos (TAGV), which aims to locate precise video segments that respond to natural language queries, is increasingly important for direct video answer retrieval. This task remains challenging due to the need to comprehend semantically complex questions and to address the significant length mismatch between untrimmed videos and short target moments. Existing methods often suffer from sensitivity to irrelevant content or insufficient visual reasoning capabilities. To tackle these limitations, we propose a Candidate-Aware Causal Reasoning (CACR) framework. Our approach first employs a Visual-Language Pre-training based Candidate Selection (VBCS) algorithm to efficiently generate K candidate segments, then applies a temporal logic reasoning module enhanced by a rejection reward mechanism and optimized via Group Relative Policy Optimization (GRPO) for robust inference. Extensive experiments on six benchmarks demonstrate that our method achieves state-of-the-art performance in terms of mean Intersection-over-Union (mIoU), providing a new perspective for reasoning-based retrieval in long videos.

Autoregressive Language Models are Secretly Energy-Based Models: Insights into t
he Lookahead Capabilities of Next-Token Prediction
Mathieu Blondel, Michael Eli Sander, Germain Vivier-Ardisson, Tianlin Liu, Vince
nt Roulet
Autoregressive models (ARMs) currently constitute the dominant paradigm for
large language models (LLMs). Energy-based models (EBMs) represent another class
of models, which have historically been less prevalent in LLM development, yet
naturally characterize the optimal policy in post-training alignment. In this
paper, we present a unified view of these two model classes. Taking the chain
rule of probability as a starting point, we establish an explicit bijection
between ARMs and EBMs in function space, which we show to correspond to a
special case of the soft Bellman equation in maximum entropy reinforcement
learning.
Building upon this bijection, we derive the equivalence between
supervised learning of ARMs and EBMs. Furthermore, we analyze the
distillation of EBMs into ARMs by providing theoretical error bounds.
Our results provide insights into the ability of ARMs to plan ahead, despite
being based on the next-token prediction paradigm.

Unlearning in Diffusion Models: A Unified Framework with KL Divergence and Likel
ihood Constraints
Shervin Khalafi, Alejandro Ribeiro, Dongsheng Ding
Unlearning in diffusion models aims to remove undesirable data or concepts while
 preserving the utility of pretrained models---two fundamentally conflicting obj
ectives. We propose a principled constrained optimization framework that formula
tes unlearning as minimizing the deviation from a pretrained model, subject to e
xplicit separation constraints from the unlearning distributions. Specifically,
we formulate three constrained optimization problems based on reverse and forwar
d KL divergences, and likelihood constraints. The first two generalize existing
approaches for concept and data unlearning, while the third offers a novel and n
atural formulation for unlearning. Despite the nonconvexity of the KL constraint
s, we establish strong duality for all three problems, enabling us to explicitly
 characterize their optimal solutions as unlearning targets and develop primal–d
ual algorithms for each formulation. Experimental results demonstrate that our K
L-constrained approach achieves superior retention-unlearning tradeoffs compared
 to weight-based baselines for concept and data unlearning, and that our likelih
ood-based approach matches unlearning effectiveness while better preserving reta
ined concepts compared to baselines.

QUATRO: Query-Adaptive Trust Region Policy Optimization for LLM Fine-tuning
Doyeon Lee, Eunyi Lyou, Hyunsoo Cho, Soo Kyung Kim, Joonseok Lee, Jaemoo Choi
GRPO-style reinforcement learning (RL)-based LLM fine-tuning algorithms have rec
ently gained popularity. Relying on heuristic trust-region approximations, howev
er, they can lead to brittle optimization behavior, as global importance-ratio c
lipping and group-wise normalization fail to regulate samples whose importance r
atios fall outside the clipping range. We propose Query-Adaptive Trust-Region po
licy Optimization (QUATRO), which directly enforces trust-region constraints thr
ough a principled optimization. This yields a clear and interpretable objective
that enables explicit control over policy updates and stable, entropy-controlled
 optimization, with a stabilizer terms arising intrinsically from the exact trus
t-region formulation. Empirically verified on diverse mathematical reasoning ben
chmarks, QUATRO shows stable training under increased policy staleness and aggre
ssive learning rates, maintaining well-controlled entropy throughout training.

DR Tulu: Reinforcement Learning with Evolving Rubrics for Deep Research
Rulin Shao, Akari Asai, Shannon Zejiang Shen, Hamish Ivison, Varsha Kishore, Jin
gming Zhuo, Xinran Zhao, Molly Park, Samuel G. Finlayson, David Sontag, Tyler Mu
rray, Sewon Min, Pradeep Dasigi, Luca Soldaini, Faeze Brahman, Wen-tau Yih, Tong
shuang Wu, Luke Zettlemoyer, Yoon Kim, Hannaneh Hajishirzi, Pang Wei Koh
Deep research agents perform multi-step research to produce long-form, well-attr

ibuted answers. However, most open deep research agents are trained on easily ve rifiable short-form QA tasks via reinforcement learning with verifiable rewards, which does not extend to realistic long-form tasks. We address this with Reinfo rcement Learning with Evolving Rubrics (RLER), where rubrics are constructed and maintained to co-evolve with the policy model during training. This allows the rubrics to incorporate newly explored information from search and contrasting mo del responses, enabling better fact checking and more discriminative on-policy f eedback. Using RLER, we develop Deep Research Tulu (DR Tulu-8B), the first fully open model that is directly trained for open-ended, long-form deep research. Ac ross four long-form deep research benchmarks in science, healthcare, and general domains, DR Tulu-8B substantially outperforms existing open deep research agent s (by 15.6% over Tongyi DR on average) and matches or exceeds proprietary deep r esearch agents (by 0.7% over OpenAI DR on average), while being significantly sm aller and cheaper per query (1000x cheaper than OpenAI DR per query).

RADIO1D: Elastic Representations for Condensed Vision Modeling

Greg Heinrich, Mike Ranzinger, Collin McCarthy, Natan Bagrov, Eugene Khvedchenya , Bryan Catanzaro, Jan Kautz, Andrew Tao, Pavlo Molchanov

This paper challenges the assumption that vision-language models (VLMs) require fixed patch-based 2D vision features. Analyzing fine-tuned vision encoders, we f ind that representations become increasingly abstract and less spatially coheren t during VLM training. Notably, models trained with image-text alignment (such a s SigLIP2) develop a small number of specialized tokens that effectively summari ze global image content. Building on this, we introduce RADIO1D, which compresse s images into a compact, variable-length 1D token sequence using multi-teacher k nowledge distillation and an autoencoder design. The resulting representations e xhibit strong hierarchical summarization, enabling accurate scene understanding– even with a single token–and support improved composition-aware image retrieval. In VLMs, RADIO1D provides flexible accuracy-efficiency tradeoffs through adjust able token counts, delivering competitive performance on diverse multimodal benc hmarks with lower computational overhead and better accuracy. We release our mod els under a permissive license.

Learning to Discover at Test Time

Mert Yuksekgonul, Daniel Koceja, Xinhao Li, Federico Bianchi, Jed McCaleb, Xiaol ong Wang, Jan Kautz, Yejin Choi, James Zou, Carlos Guestrin, Yu Sun

How can we use AI to discover a new state of the art for a scientific problem? P rior work in test-time scaling, such as AlphaEvolve, performs search by promptin g a frozen LLM. We perform reinforcement learning at test time, so the LLM can c ontinue to train, but now with experience specific to the test problem. This for m of continual learning is quite special, because its goal is to produce one gre at solution rather than many good ones on average, and to solve this very proble m rather than generalize to other problems. Therefore, our learning objective an d search subroutine are designed to prioritize the most promising solutions. We call this method Test-Time Training to Discover (TTT-Discover). Following prior work, we focus on problems with continuous rewards. We report results for every problem we attempted, across mathematics, GPU kernel engineering, algorithm desi gn, and biology. TTT-Discover sets the new state of the art in almost all of the m: (i) Erd■s' minimum overlap problem and an autocorrelation inequality; (ii) a GPUMode kernel competition (up to 2× faster than prior art); (iii) past AtCoder algorithm competitions; and (iv) denoising problem in single-cell analysis. Our solutions are reviewed by experts or the organizers. All our results are achieve d with an open model, OpenAI gpt-oss-120b, and can be reproduced with our public ly available code, in contrast to previous best results that required closed fro ntier models. Our test-time training runs are performed using Tinker, an API by Thinking Machines, with a cost of only a few hundred dollars per problem.

Efficient Continuous-Depth Modeling with GRU Equivalents

Ayan Banerjee, BIN XU, Sandeep Gupta

Continuous-Depth Neural Networks (CDNNs), including Neural Ordinary Differential

Equations (ODEs) and Liquid-Time-Constant Neural Networks (LTC-NN), suffer from high computational costs due to solving numerous nonlinear ODEs during training and inference. We introduce Continuous Depth Acceleration (CoDA), a framework that leverages Mori–Zwanzig/Koopman operator theory to replace continuous-depth layers requiring multiple nonlinear ODEs with a compact GRU module, a single low-dimensional linear ODE, and a dense layer. We prove PAC learnability of CoDA, establishing that this transformation preserves accuracy and can be applied repeatedly across multiple layers with unified backpropagation. Experiments on the Liquid Foundation Model (LFM-1.2B) demonstrate $6.7\times$ training speedup and $1.8\times$ inference speedup without loss of accuracy. Across six real-world LTC-NN applications, CoDA consistently outperforms state-of-the-art acceleration techniques—including neural flows, model order reduction, and variational formulations—in both training and inference time while maintaining competitive or superior accuracy. The implementation and datasets are publicly available at \url{https://github.com/ImpactLabASU/CoDA-ICML2026}.

****

Geometric Rate–Distortion Invariance for Domain Generalization

Tong Liu, Sen Liang, Shuo Bai

Domain generalization (DG) aims to learn representations that remain predictive under distribution shifts. A key challenge is that the target domain is unobserved during training, which complicates the search for invariant representations: alignment objectives that ignore discriminative structure can become ill-conditioned under finite samples. This calls for shaping the geometry of class-conditional representations across domains, not merely matching their distributions. We propose Geometric **R**ate–**D**istortion **I**nvariance (**RDI**), a DG framework that realizes this principle by generalizing classical rate–distortion theory to Grassmann manifolds. **RDI** models class-conditional representations as low-dimensional subspaces and formulates DG as a joint optimization of (i) cross-domain subspace alignment (geometric distortion) and (ii) spectral–volumetric complexity (a capacity-regularized rate term), promoting stable alignment while preventing the collapse of discriminative geometry. We provide finite-sample stability guarantees under bounded shifts and show on DomainBed that **RDI** is competitive with strong DG baselines, with ablations confirming that both alignment and complexity control are necessary for reliable generalization.

Beyond Model Base Retrieval: Weaving Knowledge to Master Fine-grained Neural Network Design

Jialiang Wang, Hanmo Liu, Shimin Di, Zhili Wang, Jiachuan Wang, Lei Chen, Xiaofang Zhou

Designing high-performance neural networks for new tasks requires balancing optimization quality with search efficiency. Current methods fail to achieve this balance: neural architectural search is computationally expensive, while model retrieval often yields suboptimal static checkpoints. To resolve this dilemma, we model the performance gains induced by fine-grained architectural modifications as edit-effect evidence and build evidence graphs from prior tasks. By constructing a retrieval-augmented model refinement framework, our proposed M-DESIGN dynamically weaves historical evidence to discover near-optimal modification paths. M-DESIGN features an adaptive retrieval mechanism that quickly calibrates the evolving transferability of edit-effect evidence from different sources. To handle out-of-distribution shifts, we introduce predictive task planners that extrapolate gains from multi-hop evidence, thereby reducing reliance on an exhaustive repository. Based on our model knowledge base of 67,760 graph neural networks across 22 datasets, extensive experiments demonstrate that M-DESIGN consistently outperforms baselines, achieving the search-space best performance in 26 out of 33 cases under a strict budget.

RVAS: Referring Video Active Exploration and Segmentation

Hengrui Hu, Weiwei Gao, Zipei Zhang, Henghui Ding

Existing referring video object segmentation (RVOS) is largely built on passive perception and assumes the target is already visible in the observed video, whic

h limits real-world use when queries refer to objects beyond the current view. T
o address this gap, we introduce Referring Video Active Exploration and Segmenta
tion (RVAS), a new task that focuses on reasoning about exploration policy and t
hen locating and segmenting the object according to an input referring expressio
n. To support RVAS, we build a large-scale dataset with manually annotated explo
ration actions and reference reasoning traces, enabling supervised training and
evaluation. We benchmark representative RVOS and related video understanding bas
elines and find that they struggle to perform active target search and incur sub
stantial overhead when coupled with online decision making. Motivated by these c
hallenges, we propose LESA, a baseline framework that introduces a state control
ler and hierarchical memory for efficient streaming processing and sparse MLLM r
easoning. LESA substantially reduces inference cost while maintaining competitiv
e planning quality, and consistently improves segmentation accuracy on the RVAS
dataset. Code is available at [https://github.com/FudanCVL/RVAS](https://github.
com/FudanCVL/RVAS).

SafeSearch: Automated Red-Teaming of LLM-Based Search Agents
Jianshuo Dong, Sheng Guo, Hao Wang, Xun Chen, Zhuotao Liu, Tianwei Zhang, Ke Xu,
 Minlie Huang, Han Qiu
Search agents connect LLMs to the Internet, enabling them to access broader and
more up-to-date information.
However, this also introduces a new threat surface: unreliable search results ca
n mislead agents into producing unsafe outputs.
Real-world incidents and our two in-the-wild observations show that such failure
s can occur in practice.
To study this threat systematically, we propose SafeSearch, an automated red-tea
ming framework that is scalable, cost-efficient, and lightweight, enabling sandb
oxed safety evaluation of search agents.
Using this, we generate 300 test cases spanning five risk categories (e.g., misi
nformation and prompt injection) and evaluate three search agent scaffolds acros
s 17 representative LLMs.
Our results reveal substantial vulnerabilities in LLM-based search agents, with
the highest ASR reaching 90.5\% for GPT-4.1-mini in a search-workflow setting.
Moreover, we find that common defenses, such as reminder prompting, offer limite
d protection.
Overall, SafeSearch provides a practical way to measure and improve the safety o
f LLM-based search agents.

Alignment Pretraining: AI Discourse Causes Self-Fulfilling (Mis)alignment
Cameron Tice, Puria Radmard, Samuel Ratnam, Andy Kim, David Demitri Africa, Kyle
 O'Brien
Pretraining corpora contain extensive discourse about AI systems, yet the causal
 influence of this discourse on downstream alignment remains poorly understood.
If prevailing descriptions of AI behaviour are predominantly negative, LLMs may
internalise corresponding behavioural priors, giving rise to self-fulfilling mis
alignment. This paper provides the first controlled study of this hypothesis by
pretraining 6.9B-parameter LLMs with varying amounts of (mis)alignment discourse
. We find that discussion of AI contributes to misalignment. Upsampling syntheti
c training documents about AI misalignment leads to a notable increase in misali
gned behaviour. Conversely, upsampling documents about aligned behaviour reduces
 misalignment scores from 45% to 9%. We consider this evidence of self-fulfillin
g alignment. These effects are dampened, but persist through post-training. Our
findings establish the study of how pretraining data shapes alignment priors, or
 alignment pretraining, as a complement to post-training. We recommend practitio
ners pretrain for alignment as well as capabilities.

Calibrating Conservatism for Scalable Oversight
William Overman, Mohsen Bayati
Agentic AI systems capable of autonomous planning and extended environmental int
eraction pose a fundamental control problem: how can humans maintain meaningful

oversight of systems that may exceed human capabilities? While scalable oversigh t is widely studied, existing approaches often rely on complex assumptions, rema in largely heuristic, or lack practical methods for sequential settings with sta tistical guarantees. We introduce Calibrated Collective Oversight (CCO), which a ggregates diverse auxiliary scoring functions into a penalty that measures devia tion from a conservative baseline. Inspired by Attainable Utility Preservation, CCO enables collective conservatism: when multiple oversight signals register co ncern, the agent defers. CCO calibrates this conservatism online using Conformal Decision Theory, ensuring that undesirable outcomes remain below a user-specifi ed target α with finite-time bounds and no distributional assumptions. Ex periments on SWE-bench demonstrate that weaker overseers successfully constrain an adversarially misaligned stronger agent. Similarly, on MACHIAVELLI, CCO achie ves substantial reductions in ethical violations while preserving reward. In bot h settings, empirical violation rates closely match the specified targets. Our w ork demonstrates that combining penalty-based conservatism with online calibrati on yields practical oversight with statistical guarantees suited for agentic dep loyment.

How Out-of-Distribution Detection Learning Theory Enhances Transformer: Learnabi lity and Reliability

Yijin Zhou, Yutang Ge, Wenyuan XIE, Linqian Zeng, Xiaowen Dong, Yu Guang Wang

Transformers excel in natural language processing and computer vision tasks. How ever, they still face challenges in generalizing to Out-of-Distribution (OOD) da tasets, i.e. data whose distribution differs from that seen during training. OOD detection aims to distinguish outliers while preserving in-distribution (ID) da ta performance. This paper introduces the OOD detection Probably Approximately C orrect (PAC) Theory for transformers, which establishes the conditions for data distribution and model configurations for the OOD detection learnability of tran sformers. It shows that outliers can be accurately represented and distinguished with sufficient data under conditions. The theoretical implications highlight t he trade-off between theoretical principles and practical training paradigms. By examining this trade-off, we naturally derived the rationale for leveraging aux iliary outliers to enhance OOD detection. Our theory suggests that by penalizing the misclassification of outliers within the loss function and strategically ge nerating soft synthetic outliers, one can robustly bolster the reliability of tr ansformer networks. This approach yields a novel algorithm that ensures learnabi lity and refines the decision boundaries between inliers and outliers. In practi ce, the algorithm consistently achieves state-of-the-art (SOTA) performance acro ss various data formats.

Variational Inference for Uncertain Optimal Transport via Sinkhorn Parametrizati on

Ananyapam De, Linus Bleistein, Anton Frederik Thielmann, Benjamin Säfken

Optimal Transport (OT) traditionally relies on a fixed ground cost to produce a single deterministic transport plan—a practice that overlooks the inherent varia bility and noise in real-world data. While recent sampling based approaches of O T offer a principled way to quantify this uncertainty, these are computationally prohibitive and struggle to scale. In this paper, we introduce Sinkhorn-paramet erized Variational Inference, a first scalable variational framework for perform ing posterior inference over transport plans. Our key insight is that the Sinkho rn map can be treated as a differentiable reparameterization of the set of entro pic plans. This enables the use of flexible generative models like normalizing f lows to approximate distributions over transport plans while enforcing marginal constraints. We experimentally demonstrate that our method matches the quality o f intensive sampling techniques at a fraction of the computational cost, scaling effectively to large-scale problems.

Scaling Real-World Robot Policy Evaluation via Discrete Diffusion World Model

Yaxuan Li, Junjie Wen, Zhongyi Zhou, Yefei Chen, Chaomin Shen, Yaxin Peng, Yiche n Zhu

Evaluating generalist robot manipulation policies is costly and difficult to sca
le in the real world. While emerging world models (e.g., WorldEval, Ctrl-World)
offer a promising alternative, the reliability of such evaluation remains a crit
ical bottleneck.
Specifically, their visual predictions can undermine policy assessment by "self-
correcting" failures into false positives or yielding artifacts under out-of-dis
tribution controls.
Even with failure-enriched data, current architectures struggle to capture actio
n-causal dynamics, as they typically treat actions as passive conditions rather
than causal drivers.
To address this, we propose dWorldEval, an action-centric discrete-diffusion wor
ld model that maps visual observations, language instructions, and action chunks
into a shared unified token space and denoises them with a single self-attentio
n backbone where actions function as first-class tokens.
To realize reliable policy-world interaction, dWorldEval introduces a sparse key
frame memory that anchors global scene state while preserving fine-grained multi
-view interaction cues, and leverages Progress-as-text to jointly generate futur
e observations and success indicators.
Extensive experiments on LIBERO, RoboTwin, and real-robot tasks demonstrate that
dWorldEval significantly outperforms video diffusion baselines in action contro
llability, stabilizes long-horizon multi-view rollouts, enabling accurate policy
ranking via automatic success estimation.

AG-REPA: Causal Layer Selection for Representation Alignment in Audio Flow Match
ing

Pengfei ZHANG, Tianxin Xie, Minghao Yang, Li Liu

REPresentation Alignment (REPA) improves the training of generative flow models
by aligning intermediate hidden states with pretrained teacher features, but its
effectiveness in token-conditioned audio Flow Matching critically depends on th
e choice of supervised layers, which is typically made heuristically based on th
e depth. In this work, we introduce **A**ttribution-**G**uided **REP**resentatio
n **A**lignment **(AG-REPA)**, a novel causal layer selection strategy for repre
sentation alignment in audio Flow Matching. Firstly, we find that layers that be
st store semantic/acoustic information (high teacher-space similarity) are not n
ecessarily the layers that contribute most to the velocity field that drives gen
eration, and we call it **S**tore-**C**ontribute **D**issociation **(SCD)**.
To turn this insight into an actionable training guidance, we propose a forward-
only gate ablation (FoG-A) that quantifies each layer's causal contribution via
the induced change in the predicted velocity field, enabling sparse layer select
ion and adaptive weighting for alignment. Across unified speech and general-audi
o training (LibriSpeech + AudioSet) under different token-conditioning topologie
s, AG-REPA consistently outperforms REPA baselines. Overall, our results show th
at alignment is most effective when applied to the causally dominant layers that
drive the velocity field, rather than to layers that are representationally ric
h but functionally passive.

REVIS: Sparse Latent Steering to Mitigate Object Hallucination in Large Vision-L
anguage Models

Jialin Wu, Wei Shi, Han Shen, Peigui Qi, Kunsheng Tang, Zhicong Huang, Binghao W
ang, Zhou Yang

Despite the advanced capabilities of Large Vision-Language Models (LVLMs), they
frequently suffer from object hallucination. One reason is that visual features
and pretrained textual representations often become intertwined in the deeper ne
twork layers. To address this, we propose REVIS, a training-free framework desig
ned to explicitly re-activate this suppressed visual information. Rooted in late
nt space geometry, REVIS extracts the pure visual information vector via orthogo
nal projection and employs a calibrated strategy to perform sparse intervention
only at the precise depth where suppression occurs. This surgical approach effec
tively restores visual information with minimal computational cost. Empirical ev
aluations on standard benchmarks demonstrate that REVIS reduces object hallucina

tion rates by approximately 19% compared to state-of-the-art baselines, while preserving general reasoning capabilities.
****
Neural Thickets: Diverse Task Experts Are Dense Around Pretrained Weights
Yulu Gan, Phillip Isola
Pretraining produces a learned parameter vector that is typically treated as a starting point for further iterative adaptation. In this work, we instead view the outcome of pretraining as a distribution over parameter vectors, whose support already contains task-specific experts. We show that in smaller or insufficiently trained models such expert solutions occupy a negligible fraction of the volume of this distribution, making their discovery reliant on structured optimization methods such as gradient descent. In contrast, in large, well-pretrained models the density of task-experts increases dramatically, so that diverse specialists populate a substantial fraction of the neighborhood around the pretrained weights. Motivated by this perspective, we explore a simple, fully parallel post-training method that samples N parameter vectors at random, selects the top K, and ensembles them via majority vote to combine complementary expertise. Despite its simplicity, this approach is competitive with standard post-training methods such as PPO, GRPO, and ES for contemporary large-scale models.
****
Anti-Backdoor Coreset Selection via Cumulative Entropy
Qi Zhao, Christian Wressnegger
Recent training-time defenses against neural backdoors isolate a benign subset from poisoned training data, to learn a backdoor-free model from it. In this paper, we formulate this defense strategy as a coreset selection problem, giving rise to so-called “Anti-Backdoor Coreset Selection.” Since poisonous samples have a) lower prediction uncertainty and are b) less frequent than benign samples, coreset selection naturally focuses more on samples associated with benign functionality than the backdoor functionality. We use the Cumulative Entropy as selection criterion to further facilitate this effect. The metric tracks the learning dynamics of training samples and allowing us to select benign samples with high informativeness for the coreset. Additionally, we unlearn the chosen samples in each epoch to facilitate the separability between benign and poisonous samples. Together, this yields an exceptionally effective training-time defense that constructs a benign coreset to train a backdoor-free model. Unlike prior defenses that compromise natural accuracy and fail against certain attacks, our method mitigates backdooring attacks consistently with a negligible impact on natural performance. The implementation of our method is publicly available at: https://intellisec.de/research/abcs

Mixture Prototype Flow Matching for Open-Set Supervised Anomaly Detection
Fuyun Wang, Yuanzhi Wang, Xu Guo, Sujia Huang, Tong Zhang, Dan Wang, Hui Yan, Xin Liu, Zhen Cui
Open-set supervised anomaly detection (OSAD) aims to identify unseen anomalies using limited anomalous supervision. However, existing prototype-based methods typically model normal data via a unimodal Gaussian prior, failing to capture inherent multi-modality and resulting in blurred decision boundaries. To address this, we propose Mixture Prototype Flow Matching (MPFM), a framework that learns a continuous transformation from normal feature distributions to a structured Gaussian mixture prototype space. Departing from traditional flow-based approaches that rely on a single velocity vector, MPFM explicitly models the velocity field as a Gaussian mixture prior where each component corresponds to a distinct normal class. This design facilitates mode-aware and semantically coherent distribution transport. Furthermore, we introduce a Mutual Information Maximization Regularizer (MIMR) to prevent prototype collapse and maximize normal-anomaly separability. Extensive experiments demonstrate that MPFM achieves state-of-the-art performance across diverse benchmarks under both single- and multi-anomaly settings.

Adversarial Reinforcement Learning for Robust Diffusion Large Language Model Unlearning

Zhiwei Zhang, Yudi Lin, Linlin Wu, Fali Wang, Yi Xin, Xiaomin Li, Minhua Lin, Xianfeng Tang, Qi He, Suhang Wang

Diffusion language models (DLMs) have recently emerged as an alternative to autoregressive approaches, enabling parallel sequence generation and flexible token generation orders. Machine unlearning plays a critical role in mitigating legal and ethical risks by removing the influence of specific training examples from trained models. While unlearning has been extensively studied for autoregressive language models, its applicability to DLMs remains unexplored. The architectural differences of DLMs raise new challenges for effective and robust unlearning that are not addressed by existing methods. In this paper, we present the first comprehensive study of unlearning for DLMs. Through systematic empirical analysis, we show that unlearning performance in DLMs is highly sensitive to generation hyperparameters, highlighting the need for evaluation across diverse generation settings. We further observe that DLMs tend to reproduce unlearned information when target inputs are embedded within informative contexts, due to their ability to incorporate both prefix and suffix conditioning, which increases vulnerability to elicitation attacks and weakens the robustness of existing unlearning methods. To design a robust unlearning method, we propose an adversarial reinforcement learning framework, where a context generator adversarially produces informative contexts to elicit unlearned knowledge, while the DLM is optimized to suppress undesired recall. We further introduce novel components to address credit assignment and stability issues in this adversarial learning setup. Extensive experiments demonstrate that our method significantly improves unlearning effectiveness while preserving model utility.

Capacitated Fair-Range Clustering: Hardness and Approximation Algorithms

Ameet Gadekar, Suhas Thejaswi

Capacitated fair-range k-clustering generalizes classical k-clustering by incorporating both capacity constraints and demographic fairness. In this setting, data points are categorized as clients and facilities; each facility has a capacity and may belong to one or more possibly intersecting demographic groups. The task is to select k facilities as centers and assign each client to a center so that: (a) no center exceeds its capacity, (b) the number of centers selected from each group lies within specified lower and upper bounds (fair-range constraints), and (c) the clustering cost (e.g., k-median or k-means) is minimized.

In a prior work, Thejaswi et al. (2022) showed that even satisfying fair-range constraints is NP-hard, thereby making the problem inapproximable to any polynomial factor. Our first main result strengthens this by showing that inapproximability persists even when the fair-range constraints are trivially satisfiable, highlighting the intrinsic computational complexity of the clustering task itself. These inapproximability results hold even on tree metrics and when the number of groups is logarithmic in the size of the facility set.

In light of strong inapproximability results, we focus on a practical setting where the number of groups is constant. Our second main result is a polynomial-time $O(\log k)$- and $O(\log^2 k)$-approximation algorithm for k-median and k-means objectives, respectively, in this regime. Next, we design constant factor approximation algorithms for these problems that run in fixed parameterized tractable time in k. All our approximation guarantees match the best bounds for capacitated clustering without fair-range constraints. Finally, as our third main contribution, we show that our polynomial-time algorithms are, to our knowledge, the first to have provable approximation guarantees that can practically solve problem instances of modest size.

RepetitionCurse: Measuring and Understanding Router Imbalance in Mixture-of-Experts LLMs under DoS Stress

Ruixuan Huang, Qingyue Wang, Hantao Huang, Yudong Gao, Dong CHEN, Shuai Wang, Wei Wang

Mixture-of-Experts architectures have become the standard for efficient LLM scaling, typically employing expert parallelism to distribute experts across devices. However, the absence of explicit load balancing constraints during inference allows adversarial inputs to trigger severe routing concentration. We demonstrate that out-of-distribution prompts can manipulate the routing mechanism such that all tokens are routed to the same set of top-k experts, which creates computational bottlenecks on certain devices while forcing others to idle. This converts an efficiency mechanism into a denial-of-service attack vector, leading to violations of service-level agreements for time-to-first-token (TTFT). We propose RepetitionCurse, a black-box strategy to exploit this vulnerability. By identifying a universal flaw in MoE router behavior, RepetitionCurse constructs attack prompts using simple repetitive token patterns in a model-agnostic manner. On widely deployed MoE models hosted on 8-GPU clusters, our method increases TTFT by 20% to 148%, significantly degrading service quality.

Sparse Topology-Aware Pairwise Scoring for Large-Scale Multi-Agent Reinforcement Learning

Zhibo Deng, Feng Liang, Yong Zhang, Xiaoxi Zhang, Xiping Hu

In multi-agent reinforcement learning (MARL), communication enables agents to mitigate partial observability and stochasticity through information sharing, but large-scale systems inherently lead to a rapidly growing number of pairwise interactions. Previous studies often struggle to simultaneously achieve scalability and task adaptivity in large-scale multi-agent communication. To address this challenge, we propose a scalable communication scheme for large-scale MARL, termed $\textit{Sparse tOpology-aware Pairwise Scoring}$ (SOPS). We argue that scalable MARL communication requires decoupling scalability from task-adaptive link allocation. To ensure scalability, we constrain communication to an exponential-graph backbone with a small diameter, which preserves rapid potential information mixing while keeping per-agent candidates logarithmic. On top of this constraint, we learn a task-conditioned probabilistic subgraph distribution via a pairwise scoring network over agent states and edge-type embeddings to allocate sparse links for maximizing return, optimized end-to-end through differentiable Gumbel-Sigmoid reparameterization. Evaluation results show that SOPS significantly outperforms existing state-of-the-art methods across cooperative benchmarks of diverse scales and exhibits robust zero-shot transfer capabilities.

CATArena: Evaluating Evolutionary Capabilities of Code Agents via Iterative Tournaments

Lingyue Fu, Xin Ding, Linyue Pan, Yaoming Zhu, Shao Zhang, Lin Qiu, Xuezhi Cao, Xunliang Cai, Jiaxin Ding, Weiwen Liu, Weinan Zhang, Yong Yu

Current evaluation for Large Language Model (LLM) code agents predominantly focus on generating functional code in single-turn scenarios, which fails to evaluate the agent's capability for continuous code optimization and multi-turn iterative development. To bridge this gap, we introduce CATArena, a framework designed to evaluate the evolutionary capabilities of code agents via iterative tournaments. Agents engage in multi-turn tournaments and continuously refine their code through self-reflection and peer-learning based on comprehensive execution feedback. For evaluation, we propose a dual-metric system to decouple static generation proficiency from evolutionary potential. Extensive experiments reveal that an agent's evolutionary potential is not strictly correlated with its initial proficiency. Our analysis further reveals that current agents struggle to concurrently leverage both peer-learning and self-reflection for effective performance gains. Furthermore, the results validate CATArena's high extensibility and resistance to variance tasks, establishing it as a continuous and reliable standard for assessing the evolutionary capability of LLM code agents.

ARLArena: A Unified Framework for Stable Agentic Reinforcement Learning

Xiaoxuan Wang, Han Zhang, Haixin Wang, Yidan Shi, Ruoyan Li, Kaiqiao Han, Chenyi Tong, Haoran Deng, Alexander K Taylor, Renliang Sun, Yanqiao Zhu, Jason Cong, Yizhou Sun, Wei Wang

Agentic reinforcement learning (ARL) has rapidly gained attention as a promising paradigm for training agents to solve complex, multi-step interactive tasks. Despite encouraging early results, ARL remains highly unstable, often leading to training collapse. This instability limits scalability to larger environments and longer interaction horizons, and constrains systematic exploration of algorithmic design choices.

In this paper, we first propose **ARLArena**, a stable training recipe and systematic analysis framework that examines training stability in a controlled and reproducible setting. ARLArena first constructs a clean and standardized testbed. Then, we decompose policy gradient into four core design dimensions and assess the performance and stability of each dimension. Through this fine-grained analysis, we propose **SAMPO**, a stable agentic policy optimization method designed to mitigate the dominant sources of instability in ARL.

Empirically, SAMPO achieves consistently stable training and strong performance across diverse agentic tasks. Our code is open-sourced at: https://github.com/WillDreamer/ARL-Arena.git

An Empirical Study on the Resilience of Partial Merging to Model Clone Attacks

Tiantong Wu, Yurong Hao, Wei Yang Bryan Lim

Model merging is a promising technique to enhance the capabilities of neural networks (NNs) by integrating multiple downstream fine-tuned models without requiring access to clients' raw data or substantial computation resources. However, conventional model merging typically requires collecting the full set of fine-tuned model parameters from multiple clients, which may expose them to model-privacy risks. An emerging approach, known as partial model merging (PMM), mitigates this risk by splitting each model into private and shared parts, where only the shared part is merged while the private part remains local to each client. Despite its stricter parameter fusion, PMM can still achieve competitive performance compared to full-parameter sharing. However, the privacy properties of PMM remain underexplored. In this paper, we propose a novel model clone attack and assess the risk of reconstructing the unshared private part of a partially merged model under eight attack scenarios with varying prior knowledge (i.e., partial training data, model parameters and/or model structure). Our comprehensive experiments reveal that merging NNs without adequate protection is highly vulnerable. Even when only a small fraction of training data, model parameters, or model structure is exposed, adversaries can still recover significant portions of the private model's performance.

****

Beyond External Monitors: Enhancing Transparency of Large Language Models for Easier Monitoring

Guanxu Chen, Jing Shao, Tao Luo, Lijie Hu, Qihao Lin, Dongrui Liu

Large language models (LLMs) are becoming increasingly capable, but the mechanisms of their thinking and decision-making processes remain unclear. Chain-of-thoughts (CoTs) have been commonly utilized to externalize LLMs' thinking, but this strategy fails to accurately reflect LLMs' thinking process. Techniques based on LLMs' hidden representations provide an inner perspective to improve the monitorability of their latent thinking. However, previous methods only try to develop external modules instead of making LLMs themselves easier to monitor. In this paper, we propose a novel method, TELLME, improving the transparency of LLMs and helping monitors identify unsuitable and sensitive behaviors. Furthermore, we showcase the effectiveness of TELLME on detoxification tasks, where LLMs achieve consistent improvement among multimodal test sets, distinct architectures, and varying parameter scales. We further analyze TELLME's improvement on LLMs' generalization ability from both optimal transport theory and empirical perspectives.

DuRP: Dual-Stage Physics-Embedded Learning for Joint Radiance and Polarization Restoration

Zhenshuo Yang, Qian He, Zhiyuan Liu, Baojie Fan, Jiandong Tian

Polarization information is valuable for many computer vision applications. However, in hazy environments, polarization information is severely attenuated due t

o the degradation of captured polarized images. Existing dehazing methods strugg
le to effectively restore polarization information, as single-image methods are
unaware of polarization, and polarization-based methods are constrained by the t
raditional polarization models. These deficiencies lead to inaccurate polarimetr
ic signatures and physical inconsistencies in scattering environments. To overco
me these limitations, we propose DuRP, a dual-stage physics-embedded learning fr
amework for joint restoration of scene radiance and polarization information. Sp
ecifically, we derive generalized polarization physics models that relax the ide
al assumptions of traditional theory to provide a more precise foundation for th
e joint restoration of polarimetric and amplitude information. We then design a
dual-stage neural network to estimate latent physical parameters through differe
ntiable operators, ensuring that both the polarimetric state and radiance are ac
curately recovered. Experimental results show that DuRP achieves state-of-the-ar
t performance in joint restoration and significantly enhances polarization-based
 vision tasks. Project website: [https://DuRP.github.io/](https://yangzhenshuo.g
ithub.io/DuRP.github.io/)

Gradient-Aware Scheduling: Coupling Curriculum and Staleness for Async Reinforce
ment Learning

Xinyu Zhang

Asynchronous reinforcement learning (RL) accelerates LLM training through parall
el data collection, but introduces *policy lag*: experiences are collected under
 stale policy weights, which destabilizes learning—especially on hard tasks. We
identify why: **gradient variance scales exponentially with task difficulty unde
r staleness**, because hard tasks have narrow solution spaces corresponding to s
harp loss-landscape curvature (high Hessian eigenvalues). We formalize this as a
 staleness budget optimization problem and prove that the optimal allocation f
ollows an exponential decay: $\eta^*(d) = \eta_{\text{base}} \cdot e^{-\lambda d
}$ where $\lambda = \alpha/2$ is half the Hessian growth rate. Building on this
principle, we propose **GAS (Gradient-Aware Scheduling)**, a drop-in recipe for
fast and stable asynchronous RL with three components: (i) a bandit-based curric
ulum that selects task difficulty by learning signal (ACB); (ii) execution-aware
 staleness budgets that keep slow tasks from bottlenecking rollout (EAAS); and (
iii) curriculum–staleness coupling that tightens the staleness budget as difficu
lty rises (CSC). Our mechanistic analysis validates the theoretical predictions:
 the "safe zone" of gradient coherence follows the derived exponential boundary.
 On code generation benchmarks, GAS improves Pass@1 from 39.7% to 60.1% while tr
aining at $2.3\times$ the throughput of synchronous GRPO, showing that matching
each task's staleness budget to its difficulty (and thus to its loss-landscape c
urvature) makes asynchronous RL both fast and stable.

Class-Prior Perturbation-Robust Regularization for Imbalanced Unreliable Partial
 Label Learning

Congyu Qiao, Haohao Dong, Xin Geng, Ning Xu

Imbalanced Unreliable Partial Label Learning (I-UPLL) is a challenging weakly su
pervised learning setting in which severe class imbalance and unreliable candida
te labels jointly degrade model performance. By revisiting existing approaches f
or imbalanced learning, we observe that most of them fundamentally rely on estim
ating the class prior to guide balancing operations, such as re-sampling, pseudo
-label generation, or logit adjustment. However, under I-UPLL, obtaining stable
and accurate prior estimates at the early stage of training is often unrealistic
 due to the ambiguity and unreliability of partial labels, thereby leading the m
odel to rapidly converge to a suboptimal solution. To address this issue, we pro
pose CLAPOR, a novel CLAss-PriOr perturbation-Robust regularization framework th
at fundamentally avoids dependence on accurate prior estimation. Specifically, t
he proposed regularization trains the model under deliberately perturbed class p
riors, sampled from a Dirichlet distribution that deviates from the current esti
mated prior. This design encourages consistent performance under prior uncertain
ty and naturally preserves attention to minority classes. Extensive experiments
on benchmark datasets demonstrate the effectiveness of CLAPOR across various set

tings of I-UPLL.

LLMs Lean on Priors, Not Programming Language Semantics
Aditya Thimmaiah, Jiyang Zhang, Jayanth Srinivasa, Junyi Jessy Li, Milos Gligoric
Recent work asks whether large language models (LLMs) condition their reasoning on explicit rules rather than statistical regularities from pretraining. Program execution provides a canonical instance: formal semantics define behavior through symbolic transition rules that can be systematically altered under distribution shift. We investigate whether LLMs can condition their reasoning on formal semantics through program execution and introduce PLSemanticsBench, pairing featherweight C programs with two semantic systems—small-step operational semantics and K semantics—and probing four capabilities: composing rules for final states, selecting rules when state is unmutated, sustaining such conditioning over long traces, and following supplied rules under novel semantics. To decouple semantic reasoning from syntactic familiarity, we redefine familiar operators to induce symbol-meaning conflict and introduce novel symbols defined only through the supplied rules, and stress-test models on Human-Written, LLM-Translated, and Fuzzer-Generated splits with increasing structural complexity. Across 11 frontier LLMs, strong final-state accuracy under standard semantics (up to 90%) drops sharply—by as much as 40–60% points—under semantic mutations and increasing structural complexity. Only a handful of models achieve non-zero long-horizon conditioning accuracy, and even the best systems reach just 35%. Together, these results suggest that contemporary LLMs often rely on pretrained lexical associations rather than systematically conditioning on supplied formal rules. PLSemanticsBench is publicly available at https://EngineeringSoftware.github.io/PLSemanticsBench.
****
STARCaster: Spatio-Temporal AutoRegressive Video Diffusion for Identity- and View-Aware Talking Portraits
Foivos Paraperas Papantoniou, Stathis Galanakis, Rolandos Alexandros Potamias, Bernhard Kainz, Stefanos Zafeiriou
This paper presents STARCaster, an identity-aware spatio-temporal video diffusion model that addresses both speech-driven portrait animation and dynamic viewpoint control, given an identity embedding or reference image, within a unified framework. Existing 2D speech-to-video diffusion models depend heavily on reference guidance, leading to limited motion diversity. At the same time, 3D-aware animation typically relies on inversion through pretrained tri-plane generators, which often leads to imperfect reconstructions and identity drift. We rethink reference- and geometry-based paradigms in two ways. First, we deviate from strict reference conditioning at pretraining by introducing softer identity constraints. Second, we address 3D awareness implicitly within the 2D video domain by leveraging the inherent multi-view nature of video data. STARCaster adopts a compositional approach progressing from ID-aware motion modeling, to audio-visual synchronization via lip reading-based supervision, and finally to novel view animation through temporal-to-spatial adaptation. To overcome the scarcity of 4D audio-visual data, we propose a decoupled learning approach in which view consistency and temporal coherence are trained independently. Comprehensive evaluations demonstrate that STARCaster generalizes effectively across tasks and identities, consistently surpassing prior approaches in different benchmarks.
****
Information-Theoretic Generalization Bounds for VAEs: A Role of Encoder and Latent Variable
Futoshi Futami, Masahiro Fujisawa
Despite their remarkable success, a rigorous theoretical understanding of how latent variables (LVs) govern the generalization performance of Variational Autoencoders (VAEs) remains largely elusive. Existing theoretical analyses are confined to supervised learning or models with discrete latent spaces, leaving their role in standard VAEs with continuous LVs poorly understood. This paper establishes the first information-theoretic analysis for VAEs by adapting a theoretical fr

amework from supervised learning---the leave-one-out conditional mutual information framework---to the unsupervised, continuous latent space of these models. Our analysis reveals that their generalization error is bounded solely by the information complexity of the encoder and LVs, independent of the decoder. The versatility of our framework is demonstrated through its extension to both hierarchical VAEs, for which we provide layer-wise bounds, and data generation, where we link our information-theoretic principles to a novel bound on the 2-Wasserstein distance between true and generated distributions.
****
The Geometry of Updates: Fisher Alignment at Vocabulary Scale
John Sweeney
Training-free source selection for LLM families with shared vocabularies arises in scientific string domains such as SMILES, protein, and genomic sequences, where candidate corpora share a tokenizer but differ in prediction targets. This creates an activation-dark regime: representation-similarity metrics can be uninformative without assumptions about label-conditioned error geometry, while classical update-geometry metrics are computationally prohibitive at vocabulary scale. We show that, in a shared-output head setting, representation metrics (e.g., CKA) are non-identifiable for transfer; models can share identical representations yet have orthogonal head updates. The key identity is that head Fisher alignment is exactly a cosine between kernel mean embeddings in the joint activation-error space, exposing activation, error, and coupling factors rather than requiring a materialized Fisher matrix. FisherSketch estimates this cosine directly in a single streaming pass, making K=128,256 head Fisher alignment practical with a 16 KB task signature (m=4096) and a 192 KB per-task streaming state–small enough to store next to a model hash, but encoding transfer-relevant update structure. Beyond source selection, the same signatures and marginals provide a diagnostic instrument for studying whether LLM task similarity is driven by activations, errors, or their coupling; shared-parameter and internal-layer validations, together with Llama-3.1-8B verbalizer-shift experiments, show that FisherSketch remains informative when activation similarity cannot distinguish tasks.
****
Bayes-inspired Integration of Pretrained Priors and Few-Shot Evidence for Few-Shot Classification
Mingyang Zhou, Xiaoxuan Zhang, Gang Liu, Yuhong Feng, Xiaoqun Wu, Hao Liao, Rui Mao
Few-shot classification aims to adapt a pretrained model to novel classes with limited examples. While current methods often heuristically combine pretrained knowledge and few-shot evidence, we seek a more principled understanding of their relationship.
In this paper, we propose a Bayesian-inspired optimal integration framework(BOIF) that interprets pretrained models as priors and few-shot evidence as likelihoods. Under conditional independence approximation, we show that the optimal log-posterior decomposes into the sum of prior logits and likelihood logits. This leads to a simple yet effective design principle: decouple the prior and likelihood pathways and combine their logits additively.
Guided by this principle, we implement BOIF using CLIP with two novel enhancements: (1) a multi-level feature adapter to enrich visual representations, and (2) a simplified cache module for likelihood estimation. Extensive experiments on 11 benchmarks show BOIF achieves state-of-the-art performance (e.g., 80.61\% average accuracy at 16-shot) and strong out-of-distribution robustness. Our work provides both a principled perspective and an effective instantiation for few-shot adaptation.
****
Auto-regressive In-context Demonstration Selection
Yunzhe Qi, Sirui Chen, Jiaru Zou, Jingrui He
Effective demonstration selection is crucial for maximizing large language model (LLM) performance in few-shot in-context learning.
Because of effects such as recency bias, the effectiveness of demonstrations depends heavily on their contextual relationship to the specific query and on t

he ordering in which they are presented, making demonstration selection a comple
x combinatorial problem.

To address these two challenges, we introduce AutoSelect, a novel framework
that formulates demonstration selection as an auto-regressive sequential decisio
n process. At each step, AutoSelect embeds the query and previously selected dem
onstrations into matrix representations to preserve structural information, and
a trainable policy model sequentially selects the next best exemplar. To navigat
e the factorial space of demonstration permutations, our framework formulates a
Kullback-Leibler (KL)-regularized optimization problem, from which an optimal po
licy induces an optimal Plackett-Luce (PL) ranking over all possible demonstrati
on sequences. We prove that minimizing a tractable policy-level cross-entropy (C
E) loss provably bounds the worst-case discrepancy between our policy's induced
PL ranking and the optimal one, enabling tractable prioritization of high-qualit
y sequences. Empirically, AutoSelect outperforms existing heuristic and learning
-based methods across nine diverse datasets, achieving up to an 11\% improvement
over the strongest baseline.

Analytical studies and a case study further highlight AutoSelect's key prope
rties, as well as its transferability and generalizability.

What If We Let Forecasting Forget? A Sparse Bottleneck for Cross-Variable Depend
encies

Fan Zhang, Shiming Fan, Hua Wang

Multivariate time series forecasting is critical in many real-world systems, and
thus modeling cross-channel dependencies is essential. Although existing method
s improve overall accuracy by enhancing representations and cross-channel intera
ctions, it remains challenging to reliably capture inter-variable dependencies u
nder specific conditions. We observe that dependencies in real data are often st
ate-dependent and noisy; in such cases, dense interactions can amplify spurious
correlations and lead to representation over-smoothing, which may yield unreliab
le predictions in certain scenarios. Motivated by this, we propose MS-FLOW, a sp
arse-bottleneck framework that explicitly models inter-variable interaction as c
apacity-limited information flow. Specifically, MS-FLOW replaces fully connected
communication with selective sparse routing, retaining only a few critical depe
ndency paths and injecting cross-variable signals under a strict communication b
udget, thereby suppressing redundant connections and spurious-correlation propag
ation. Extensive experiments demonstrate that MS-FLOW learns more reliable multi
variate correlations, achieving state-of-the-art forecasting accuracy on 12 real
-world benchmarks while producing fewer yet more reliable dependencies, shifting
multivariate forecasting from “more interaction” to “more effective interaction
”.

Forward-Chaining Temporal Point Process

Chao Yang, Wendi Ren, Shuang Li

Event sequences from complex systems, such as clinical workflows, are often spar
se and incomplete. As a result, downstream models are trained on data that only
partially captures the underlying dynamics. Synthetic sequence generation can au
gment real data by filling in missing structure and improving coverage of rare p
atterns, but generated trajectories must remain realistic, satisfy domain constr
aints, and allow control. We propose the Forward-Chaining Temporal Point Process
(FC-TPP), a framework for constraint-aware and controllable sequence generation
in continuous time. FC-TPP maintains an explicit latent symbolic state encoding
high-level predicates, which evolves through a differentiable multi-hop forward
-chaining operator. Logical rules update the latent state based on recent events
, while a temporal point process decoder generates future event times and types
conditioned on this evolving state. By tying the generative dynamics to multi-ho
p reasoning in latent space, FC-TPP incorporates symbolic structure throughout g
eneration rather than relying directly on raw event histories. Experiments on sy
nthetic data and four semi-synthetic/real-world benchmarks—LogiCity, MIMIC-IV, E
PIC-100, and IKEA ASM—show that FC-TPP achieves higher generation quality under
limited and incomplete data, with stronger constraint adherence and greater cont

rollability than purely neural and prior neuro-symbolic baselines.

LearniBridge: Learnable Calibration of Feature Caching for Diffusion Models Acce leration
Xuyue Huang, Zhe Chen, Wang Shen, Xiao-Ping Zhang
Diffusion Transformers (DiTs) have driven substantial progress in image and vide o generation but suffer from prohibitive computational costs.
Feature caching accelerates inference by reusing intermediate representations.
Existing methods rely on historical features for implementation simplicity,
yet suffer from severe error accumulation at high acceleration ratios.
To address this limitation, we investigate the nature of the requisite feature c orrection.
We demonstrate that the optimal calibration update is characterized by a shared low-rank subspace across diverse prompts.
Guided by this structural insight, we propose LearniBridge, a learnable calibrat ion mechanism for feature caching that bridges multiple timesteps through lightw eight LoRA updates.
This mechanism enables effective calibration requiring only $3-5$ training sampl es.
Extensive experiments on image and video generation show that LearniBridge achie ves up to $5.87\times$, $5.75\times$, and $4.10\times$ acceleration
on FLUX, HunyuanVideo, and WAN 2.1, respectively. On WAN 2.1, it improves VBench by 1.28\% over the previous SOTA at $4.10\times$ acceleration.

Olmix: A Framework for Data Mixing Throughout LM Development
Mayee F Chen, Tyler Murray, David Heineman, Matt Jordan, Hannaneh Hajishirzi, Christopher Re, Luca Soldaini, Kyle Lo
Data mixing---determining the ratios of data from different domains---is a first-order concern for training language models (LMs), but existing mixing methods have poorly understood design choices and assume that the set of domains remain fixed throughout development. We present Olmix, a framework that addresses two challenges encountered during LM development. First, the configuration space for developing a mixing method is not well understood---design choices across existing methods lack justification or consensus and overlook practical issues like data constraints. We conduct a comprehensive empirical study of this space, identifying which design choices lead to a strong mixing method. Second, the domain set evolves throughout LM development as datasets are revised and expanded---a problem setting largely unaddressed by existing works. We study how to efficiently recompute the mixture after the domain set is updated, given an existing mix from before the update. We introduce mixture reuse, a mechanism that reuses existing relative ratios and recomputes ratios only for domains affected by an update. Over a sequence of five domain-set updates mirroring real-world LM development, mixture reuse matches the performance of fully recomputing the mix after each update with 74% less compute and improves over training without mixing by 11.6% on downstream tasks.

Strategy Executability in Mathematical Reasoning: Leveraging Human–Model Differences for Effective Guidance
Weida Liang, Yiyou Sun, Shuyuan Nan, Chuang Li, Dawn Song, Kenji Kawaguchi
Example-based guidance is widely used to improve mathematical reasoning at inference
time, yet its effectiveness is highly unstable across problems and models—even when the
guidance is correct and problem-relevant.
We show that this instability arises from a previously underexplored gap between
strategy usage—whether a reasoning strategy appears in successful solutions—and
strategy executability—whether the strategy remains effective when instantiated
as guidance for a target model.
Through a controlled analysis of paired human-written and model-generated solutions, we
identify a systematic dissociation between usage and executability: human- and
model-derived strategies differ in structured, domain-dependent ways, leading to
complementary strengths and consistent source-dependent reversals under guidance.
Building on this diagnosis, we propose *Selective Strategy Retrieval* (SSR), a
test-time framework that explicitly models executability by selectively retrieving and
combining strategies using empirical, multi-route, source-aware signals.
Across multiple mathematical reasoning benchmarks, SSR yields reliable and consistent
improvements over direct solving, in-context learning, and single-source guidance,
improving accuracy by up to $+13$ points on AIME25 and $+5$ points on Apex for compact
reasoning models. Code and benchmark are publicly available at: https://github.com/lwd17/strategy-execute-pipeline.

TD-VAD: Breaking Visual Dependence in Video Anomaly Detection with Text-Driven L
earning
Shuangqing Zhang, Lei-Lei Ma, Zhao Wang, Wen Dong, Xinyi Xu, Guo-Sen Xie, Caifen
g Shan, Fang Zhao
Visual data is typically a prerequisite for training existing video anomaly dete
ction (VAD) methods. However, obtaining sufficient annotated anomaly data for tr
aining is challenging and not scalable due to the rarity of anomaly data and the
 wide variety of abnormal events. In this work, we advocate that the effectivene
ss of treating texts as video sequences for the VAD model and propose a novel Te
xt-Driven Video Anomaly Detection (TD-VAD) approach to break visual dependence.
In contrast to the anomaly video data, text descriptions of abnormal events are
easy to collect, and their class labels can be directly derived. Specifically, o
ur method utilizes video-like text descriptions with temporal characteristics ge
nerated by LLM to train a VAD model, without any reliance on target-domain anoma
ly data. To capture the
long and short-range temporal logic of events, we design the event evolution cau
sal attention module to model contextual dependencies across time. During infere
nce, considering the domain gap between the texts and video sequences, we use th
e frozen CLIP encoder to extract embeddings of video frames to align the text mo
dality while retaining crucial visual information. Comprehensive experiments on
two large-scale VAD datasets, XD-Violence and UCF-Crime, demonstrate that our me
thod outperforms prior one-class and unsupervised VAD methods by a large margin.

EGG: An Expert-Guided Agent Framework for Kernel Generation
Yaochen Han, Ke Fan, Hongxu Jiang, Wanqi Xu, Weiyu Xie, Runhua Zhang, Chenhui Zh
u, Yixiang Zhang
High-performance GPU kernels are critical for reducing the exponentially growing
 computational costs of large language models (LLMs), but their development heav
ily relies on manual tuning by domain experts. While recent advances in LLM-base
d approaches show promise for automating kernel generation, they still struggle
to achieve both correctness and high performance. This limitation primarily aris
es from the lack of domain-specific optimization guidance, hindering effective e
xploration of the optimization space. We propose $\textbf{EGG}$, an $\underline{
E}$xpert-$\underline{G}$uided Agent Framework for Kernel $\underline{G}$eneratio
n, which incorporates expert optimization principles to guide LLMs' decisions. I
nspired by expert workflows, we decompose kernel generation into two hierarchica
l stages: 1) algorithmic structure design, which establishes a high-quality comp
utational structure foundation; 2) hardware-specific tuning, which performs targ
eted adjustments through parallel mapping, tensor tiling, and memory optimizatio
n. This staged decomposition defines explicit optimization objectives, structuri
ng the design space to achieve progressive refinements. To this end, a stage-awa
re multi-agent collaboration mechanism is designed for inter and intra-stage con
text management, ensuring stable optimization trajectories. Experiments on Kerne
lBench and real-world workloads show that EGG achieves a $2.13\times$ average sp
eedup over PyTorch, outperforming existing agent-based and RL-based approaches.

AOrchestra: Automating Sub-Agent Creation for Agentic Orchestration
Jianhao Ruan, Zhihao Xu, Yiran Peng, Fashen Ren, Zhaoyang Yu, Xinbing Liang, Jin
yu Xiang, Yongru Chen, Bang Liu, Chenglin Wu, Yuyu Luo, Jiayi Zhang
Language agents have shown strong promise for task automation. Realizing this pr
omise for increasingly complex, long-horizon tasks has driven the rise of a suba
gent-as-tools paradigm for multi-turn task solving. However, existing designs st
ill lack a dynamic abstraction view of sub-agents, thereby hurting adaptability:
 sub-agents are either context-isolated threads that lack specialization, or sta
tic roles that require human-engineering.
We address this challenge with a unified, framework-agnostic agent abstraction t
hat models any agent as a tuple (Model, Task, Tools, Context). This tuple acts a
s a compositional recipe for capabilities, enabling the system to spawn speciali
zed executors for each task on demand.
Building on this abstraction, we introduce an agentic system AOrchestra, where t

he central orchestrator concretizes the tuple at each step: it curates task-rele vant context, selects tools and models, and delegates execution via on-the-fly a utomatic agent creation.
Such designs enable reducing human engineering efforts, and remain framework-agn ostic with plug-and-play support for diverse agents as task executors. It also e nables a controllable performance–cost trade-off, allowing the system to approac h Pareto-efficient.
Across three challenging benchmarks and environments (GAIA, SWE-Bench, Terminal-Bench), AOrchestra achieves 16.28% relative improvement against the strongest ba seline when paired with Gemini-3-Flash.

Executable Agentic Memory for GUI Agent
Zerui Qin, Sheng Yue, Xingyuan Hua, Yongjian Fu, Ju Ren
Modern GUI agents typically rely on a model-centric and step-wise interaction pa radigm, where LLMs must re-interpret the UI and re-decide actions at every scree n, which is fragile in long-horizon tasks. In this paper, we propose Executable Agentic Memory (EAM), a structured Knowledge Graph (KG) that shifts GUI planning from free-form generation to a robust retrieval-and-execution process. Our appr oach includes a sample-efficient memory construction pipeline using state-aware DFS and action-group mining to compress multi-step routines. To ensure efficient planning, we introduce a value-guided graph search where a lightweight Q-functi on model steers Monte Carlo Tree Search (MCTS) over the KG. We theoretically est ablish bias-consistency for the Q-model and derive sample complexity bounds for path recovery. Empirically, EAM outperforms state-of-the-art baselines like UI-T ARS-7B by up to 19.6% on AndroidWorld, while reducing token costs $6\times$ r elative to GPT-4o. With a 2.8s average latency, EAM enables reliable, quick, a nd long-horizon GUI automation.
****

Conditional KRR: Injecting Unpenalized Features into Kernel Methods with Applica tions to Kernel Thresholding
Rustem Takhanov, Zhenisbek Assylbekov
Conditionally positive definite (CPD) kernels are defined with respect to a func tion class $\mathcal{F}$.
It is well known that such a kernel K is associated with its native space (def ined analogously to an RKHS), which in turn gives rise to a learning method --- called conditional kernel ridge regression (conditional KRR) due to its analogy with KRR --- where the estimated regression function is penalized by the square of its native space norm. This method is of interest because it can be viewed as classical linear regression, with features specified by $\mathcal{F}$, followed by the application of standard KRR to the residual (unexplained) component of t he target variable. Methods of this type have recently attracted increasing atte ntion.

We study the statistical properties of this method by reducing its behavior to t hat of KRR with another fixed kernel, called the residual kernel. Our main theor etical result shows that such a reduction is indeed possible, at the cost of an additional term in the expected test risk, bounded by $\mathcal{O}(1/\sqrt{N})$, where N is the sample size and the hidden constant depends on the class $\mat hcal{F}$ and the input distribution.

This reduction enables us to analyze conditional KRR in the case where K is po sitive definite and $\mathcal{F}$ is given by the first k principal eigenfunct ions in the Mercer decomposition of K. We also consider the setting where $\ma thcal{F}$ consists of k random features from a random feature representation o f K. It turns out that these two settings are closely related. Both our theore tical analysis and experiments confirm that conditional KRR outperforms standard KRR in these cases whenever the $\mathcal{F}$-component of the regression funct ion is more pronounced than the residual part.

RoboMME: Benchmarking and Understanding Memory for Robotic Generalist Policies

Yinpei Dai, Hongze Fu, Jayjun Lee, Yuejiang Liu, Haoran Zhang, Jianing Yang, Chelsea Finn, Nima Fazeli, Joyce Chai
Memory is critical for long-horizon and history-dependent robotic manipulation. Such tasks often involve counting repeated actions or manipulating objects that become temporarily occluded. Recent vision-language-action (VLA) models have begun to incorporate memory mechanisms; however, their evaluations remain confined to narrow, non-standardized settings. This limits systematic understanding, comparison, and progress measurement. To address these challenges, we introduce **RoboMME**: a large-scale standardized benchmark for evaluating and advancing VLA models in long-horizon, history-dependent scenarios. Our benchmark comprises 16 manipulation tasks constructed under a carefully designed taxonomy that evaluates *temporal*, *spatial*, *object*, and *procedural* memory. We further develop a suite of 14 memory-augmented VLA variants built on the $\pi_{0.5}$ backbone to systematically explore different memory representations across multiple integration strategies. We show that the effectiveness of memory representations is highly task-dependent, with each design offering distinct advantages and limitations across different tasks. Videos and code can be found at https://robomme.github.io

SAW-Bench: Learning Situated Awareness in the Real World
Chuhan Li, Rilyn R. Han, Joy Hsu, Yongyuan Liang, Rajiv Dhawan, Jiajun Wu, Ming-Hsuan Yang, Xin Eric Wang
A core aspect of human perception is *situated awareness*, the ability to relate ourselves to the surrounding physical environment and reason over possible actions in context. However, most existing benchmarks for multimodal foundation models (MFMs) emphasize **environment-centric** spatial relations (relations among objects in a scene), while largely overlooking **observer-centric** relationships that require reasoning relative to agent's viewpoint, pose, and motion. To bridge this gap, we introduce SAW-Bench (**S**ituated **A**wareness in the Real **W**orld), a novel benchmark for evaluating egocentric situated awareness using real-world videos. SAW-Bench comprises 786 self-recorded videos captured with Ray-Ban Meta (Gen 2) smart glasses spanning diverse indoor and outdoor environments, and over 2071 *human-annotated* question-answer pairs. It probes a model’s observer–environment understanding with *six* different awareness tasks. Our comprehensive evaluation reveals a human-model performance gap of 37.66%, even with the best-performing MFM, Gemini 3 Flash. Beyond this gap, our in-depth analysis uncovers several notable findings; for example, while models can exploit partial geometric cues in egocentric videos, they often fail to infer a coherent camera geometry, leading to systematic spatial reasoning errors. We position SAW-Bench as a benchmark for situated spatial intelligence, moving beyond passive observation to understanding physically grounded, observer-centric dynamics.

SlerpFlow: Spherical Trajectory Correction for Rectified Flow Inversion
Wenbin Duan, Yan Shu, Zhuoyuan Fu, Fangmin Zhao, Yan Li, Yaru Zhao, Binyang Li
Rectified-flow-based diffusion transformers, particularly FLUX, have demonstrated outstanding performance in high-quality image generation. However, achieving fast and accurate inversion—transforming images back to latent noise for faithful reconstruction and editing—remains a challenging bottleneck due to the discretization errors of linear solvers. This paper introduces SlerpFlow, a straightforward yet highly effective zero-shot approach that unlocks the full potential of FLUX for high-fidelity inversion and editing. Unlike existing approaches (e.g., RF-Solver) that rely on complex numerical approximations such as high-order Taylor expansions to correct trajectory errors, we present a geometric view based on the Manifold Hypothesis: the empirically observed trajectory curvature is not a numerical artifact, but rather serves as a necessary “centripetal force” that constrains the flow to remain on the data manifold. Guided by this insight, SlerpFlow integrates Spherical Linear Interpolation (Slerp) to rectify flow velocity directions on the hypersphere, strictly adhering to the intrinsic curvature of the latent space. Crucially, by caching the corrected velocity for subsequent steps, SlerpFlow achieves high-precision inversion while maintaining the computation

al efficiency of a first-order Euler solver. Extensive experiments on FLUX-based reconstruction and editing tasks demonstrate that SlerpFlow improves reconstruction fidelity and achieves stronger semantic alignment in editing without requiring additional training. Code is available at https://github.com/0answer0/SlerpFlow.

Riemannian Networks over Full-Rank Correlation Matrices

Ziheng Chen, Xiaojun Wu, Bernhard Schölkopf, Nicu Sebe

Representations on the Symmetric Positive Definite (SPD) manifold have garnered significant attention across different applications. In contrast, the manifold of full-rank correlation matrices, a normalized alternative to SPD matrices, remains largely underexplored. This paper introduces Riemannian networks over the correlation manifold, leveraging five recently developed correlation geometries. We systematically extend basic layers, including Multinomial Logistic Regression (MLR), Fully Connected (FC), and convolutional layers, to these geometries. Besides, we present methods for accurate backpropagation for two correlation geometries. Experiments comparing our approach against existing SPD and Grassmannian networks demonstrate its effectiveness.

****

A Strictly Proper Scoring Rule and a Calibration Metric for Interval-Censored Data Analysis

Hiroki Yanagisawa, Shunta Akiyama

Interval-censored data present unique challenges in statistical analysis due to the partial observability of event times within known intervals, requiring assumptions about the censoring mechanism. This paper explores the theoretical relationship between two foundational assumptions: independent monitoring and non-informative censoring. We demonstrate that these assumptions are equivalent for Case-1 interval-censored data, but not for Case-K interval-censored data, where $K \geq 2$, through a synthetic dataset example. Additionally, we propose the first strictly proper scoring rule and calibration metric specifically designed for interval-censored data under the constant-sum assumption and the non-informative censoring assumption, respectively. Our empirical evaluations on real-world datasets show that a neural network model trained with our scoring rule is competitive with established statistical baselines, offering enhanced flexibility. These contributions provide significant advancements in the theoretical understanding and practical analysis of interval-censored data.

****

Retrieval-Aware Distillation for Transformer-SSM Hybrids

Aviv Bick, Eric P. Xing, Albert Gu

State-space models (SSMs) offer efficient sequence modeling but lag behind Transformers on benchmarks that require in-context retrieval. Prior work links this gap to a small set of attention heads, termed Gather-and-Aggregate (G&A), which SSMs struggle to reproduce. We propose *retrieval-aware distillation*, which converts a pretrained Transformer into a hybrid student by preserving only these retrieval-critical heads and distilling the rest into recurrent heads. We identify the essential heads via ablation on a synthetic retrieval task, producing a hybrid with sparse, non-uniform attention placement. We show that preserving **just 2% of attention heads recovers over 95% of teacher performance on retrieval-heavy tasks** (10 heads in a 1B model), requiring far fewer heads than hybrids that retain at least 25%. We further find that large recurrent states often compensate for missing retrieval: once retrieval is handled by these heads, the SSM backbone can be simplified with limited loss, even with an 8× reduction in state dimension. By reducing both the attention cache and the SSM state, the resulting hybrid is 5–6× more memory-efficient than comparable hybrids, closing the Transformer–SSM gap at a fraction of the memory cost.

LiveNewsBench: Evaluating Web Search Agents with Freshly Curated News

Yunfan Zhang, Kathleen McKeown, Smaranda Muresan

Large Language Models (LLMs) with agentic web search capabilities show strong potential for tasks requiring real-time information access and complex fact retrie

val, yet evaluating such systems remains challenging. We introduce LiveNewsBench , a rigorous and regularly updated benchmark designed to assess the agentic web search abilities of LLMs. LiveNewsBench automatically generates fresh question-a nswer pairs from recent news articles, ensuring that questions require informati on beyond an LLM's training data and enabling clear separation between internal knowledge and search capability. The benchmark features intentionally difficult questions requiring multi-hop search queries, page visits, and reasoning, making it well-suited for evaluating agentic search behavior. Our automated data curat ion and question generation pipeline enables frequent benchmark updates and supp orts construction of a large-scale training dataset for agentic web search model s, addressing the scarcity of such data in the research community. To ensure rel iable evaluation, we include a subset of human-verified samples in the test set. We evaluate a broad range of systems using LiveNewsBench, including commercial and open-weight LLMs as well as LLM-based web search APIs. The leaderboard, data sets, and code are publicly available at \url{livenewsbench.com}.

Directly Optimizing Natural Language Explanations for Behavioral Faithfulness: S imulatability and Recoverability

Advaith Malladi, Shashank Srivastava

Natural-language explanations are widely used to interpret machine learning mode ls, yet many prioritize human plausibility over accurately reflecting or predict ing model behavior. Prior approaches often rely on human-written rationales, pro ducing post-hoc explanations that neither align with the model’s decision functi on nor generalize. We introduce $\textbf{OPeX}$, a natural-language explanation model that directly optimizes for behavioral faithfulness: the ability of an exp lanation to reflect and predict a model’s observable input–output behavior. $\te xtbf{OPeX}$ is trained using reinforcement learning with Group Relative Policy O ptimization (GRPO), optimizing two complementary metrics: recoverability, which measures whether explanations recover model predictions on seen examples, and si mulatability, which measures prediction of model behavior on unseen inputs. Acro ss structured and text-based tasks, $\textbf{OPeX}$ achieves high simulatability (~0.85) and recoverability (~0.99), outperforming GPT-4o, LLaMA-3.3-70B, MaNtLE , Chain-of-Thought (CoT)-based models, and human-written explanations, despite u sing an 8B-parameter backbone. Human user studies show a 15% improvement in clas sification accuracy over competent baselines.

WaveSSM: Multiscale State-Space Models for Non-stationary Signal Attention

Ruben Solozabal, Velibor Bojkovic, Hilal AlQuabeh, Klea Ziu, Kentaro Inui, Marti n Taká■

State-space models (SSMs) have emerged as a powerful foundation for long-range s equence modeling, with the HiPPO framework showing that continuous-time projecti on operators can be used to derive stable, memory-efficient dynamical systems th at encode the past history of the input signal. However, existing projection-bas ed SSMs often rely on polynomial bases with global temporal support, whose induc tive biases are poorly matched to signals exhibiting localized or transient stru cture. In this work, we introduce \emph{WaveSSM}, a collection of SSMs construct ed over wavelet frames. Our key observation is that wavelet frames yield a local ized support on the temporal dimension, useful for tasks requiring precise local ization. Empirically, we show that on equal conditions, \textit{WaveSSM} outperf orms orthogonal counterparts as S4 on real-world datasets with transient dynamic s, including physiological signals on the PTB-XL dataset and raw audio on Speech Commands.

Causal Effect Identifiability in the Presence of Latent Confounders Without Auxi liary Variables

Xiu-Chuan Li, James Kwok, Jiaxian Guo, Tongliang Liu

It is a fundamental challenge to ascertain whether the causal effect of a treatm ent on an outcome is identifiable in the presence of latent confounders, which s erves as the logical prerequisite for recovering the causal effect in a partiall y observed system. While prior literature demonstrates that the causal effect is

identifiable when there exist auxiliary variables subject to stringent structural constraints, this paper investigates identifiability of the causal effect without such variables. This means that we ground identifiability solely in the joint distribution of the treatment-outcome pair, which constitutes the irreducible statistical basis for causal effect identification. Focusing on linear structural causal models (SCMs), we provide a nuanced and complete characterization of identifiability of the causal effect contingent on the distributional properties of exogenous noises. Specifically, we formulate a set of mutually exclusive and collectively exhaustive conditions regarding the Gaussianity of exogenous noises, ascertain under which conditions the causal effect is identifiable and under which it is not, while also quantifying the cardinality of the feasible solution set for the unidentifiable cases. Finally, we empirically validate our theoretical findings.

****

A Bayesian Approach to Quantify the Uncertainty of Human Ratings in a Single-Instance Multimodal Framework

Zijian Chen, Archana Venkataraman

Human ratings are central to learning and inference across several application domains, but they are also subject to inter-rater biases and judgment errors. Quantifying the uncertainty of these human ratings would require repeated measurements, which are expensive and rarely available at scale. We propose a Bayesian graphical model to estimate the instance-level and item-level uncertainty of (subjective) human ratings by leveraging auxiliary (objective) data. Our model learns a shared latent content representation that explains factors common to both the human rating and auxiliary data and a latent uncertainty variable that captures fluctuations in the human assessments via a data-conditioned prior. We develop a scalable amortized variational inference procedure that uses modality-appropriate neural encoders and decoders to represent the posterior factors. Experiments on synthetic data demonstrate that our framework can accurately recover the latent uncertainty under targeted ablations and stress tests. We further demonstrate our approach on a real-world dataset of paired functional MRI scans and behavioral testing for autism, thus highlighting the need for uncertainty quantification.

Bootstrapped Exploration with Causal Reasoning: A Training Paradigm for Adaptive Forecasting Agent

Qingwen Zeng, Dajun Guo, Zhaoge Bi, lining chen, Jushang Qiu, Yitian Yang, Carl Yang, Huaming Chen, Ling Chen

Time series forecasting is critical in domains such as finance, energy, and healthcare, yet real-world datasets often exhibit non-stationarity, noise, missing values, and distribution shifts, posing severe challenges for generalization. In practice, industry solutions typically rely on customized forecasting frameworks that combine imputation, decomposition, and specialized models. However, such frameworks are costly to engineer and maintain. Moreover, we observe that many frameworks suffer from the impacts of distribution shifts, which degrade their respective performance. It motivates a paradigm that transfers reliably across heterogeneous datasets while accumulating reusable strategy knowledge for large-scale, dynamic environments. Although large language model-based agents have recently shown strong reasoning and tool-use capabilities, existing approaches do not consistently adapt forecasting workflows across diverse time series. We identify two primary factors, including limited strategy-level supervision and the inherent complexity of mapping dataset-specific meta-features to effective forecasting strategies. To address these challenges, we propose BECRA, a novel agent training paradigm that learns forecasting intelligence through contrast-aware exploration and agent-level causal lesson extraction, without human-annotated supervision. BECRA distills symbolic strategy lessons that support in-context planning on unseen datasets, enabling zero-shot training adaptation.

Rethinking Attention in Spiking Transformers: Overcoming Density Bias with Set Similarity

JinGyo Lim, Seung Gyu Jeong, Seong-Eun Kim
Recent Spiking Transformer models have explored a variety of attention mechanism
s beyond standard dot-product formulations. However, many existing similarity-ba
sed spiking attention formulations remain inherently sensitive to firing density
, causing neurons with high spike rates to dominate attention scores regardless
of semantic relevance. This density bias is particularly problematic in event-dr
iven spiking representations, where sparse spike patterns often carry critical i
nformation. To address this limitation, we rethink spiking attention from a set-
theoretic perspective. We propose DiceFormer, a novel Spiking Transformer archit
ecture driven by Spike Dice Attention (SDA). Unlike traditional approaches, SDA
replaces density-sensitive measures with a set similarity function derived from
the Dice coefficient. By explicitly normalizing for firing density, SDA focuses
on spike co-occurrence rather than high firing rates. We primarily evaluate Dice
Former on the challenging audio domain, where spike sparsity varies substantiall
y across inputs. On AudioSet-20k, DiceFormer achieves a SOTA mAP of 0.161 with 5
4.3M parameters, outperforming prior SNN-based approaches and substantially narr
owing the performance gap with ANN-based models. We also introduce Lin-SDA, a li
nearized version for computation efficiency, while achieving performance compara
ble to SDA. Beyond audio, we evaluate the effectiveness of SDA on CIFAR-100 to v
erify its applicability to the vision domain.

BizFinBench.v2: Towards Reliable LLMs in Finance via Real-User Data and Offline/
Online Bilingual Evaluation
Xin Guo, Rongjunchen Zhang, Guilong Lu, Xuntao Guo, Jia Shuai, Zhi Yang, Liwen Z
hang
Large language models are becoming increasingly significant in financial applica
tions. Nevertheless, prevailing benchmarks are largely dependent on simulated or
 generic data, which leads to a significant gap between reported performance and
 actual efficacy in real-world scenarios. To tackle this challenge, we present B
izFinBench.v2, the first integrated offline and online benchmark built upon auth
entic user query-response data from both Chinese and U.S. equity markets. It com
prises 28,860 questions across eight offline and two online tasks. Experimental
results show that GPT-5 achieves a mere 61.5\% accuracy, still failing to meet t
he practical business requirement (84.8\%). Among the evaluated commercial model
s, DeepSeek-R1 exhibits superior investment efficacy. Error analysis grounded in
 real financial practice reveals persistent limitations in existing models. By o
vercoming the constraints of prior benchmarks, BizFinBench.v2 provides a substan
tiated foundation for advancing LLM deployment in the financial sector. Our data
 and code are available at https://github.com/HiThink-Research/BizFinBench.v2.
****
Controlling the Risk of Corrupted Contexts for Language Models via Early-Exiting
Andrea Wynn, Metod Jazbec, Charith Peris, Rinat Khaziev, Anqi Liu, Daniel Khasha
bi, Eric Nalisnick
Large language models (LLMs) can be influenced by harmful or irrelevant context,
 which can significantly harm model performance on downstream tasks. This motiva
tes principled designs in which LLM systems include built-in mechanisms to guard
 against such "garbage in, garbage out" scenarios. We propose a novel approach t
o limit the degree to which harmful context can degrade model performance. First
, we define a baseline "safe" behavior for the model -- the model's performance
given no context at all (zero-shot). Next, we apply distribution-free risk contr
ol (DFRC) to control the extent to which the user-provided context can decay per
formance below this safe zero-shot baseline. We achieve this by leveraging dynam
ic early exit prediction, ignoring later attention heads that attend the most to
 the unsafe inputs. Finally, we propose modifications to DFRC that allow it to b
oth control risk for harmful inputs *and* leverage performance and efficiency ga
ins on helpful inputs. We present both theoretical and empirical results across
 9 tasks spanning in-context learning and open-ended question answering, showing
 that our approach can effectively control risk for harmful context and simultan
eously achieve substantial computational efficiency gains with helpful context.
****

Scaling Agentic Verifier for Competitive Coding
Zeyao Ma, Jing Zhang, Xiaokang Zhang, Jiaxi Yang, Zongmeng Zhang, Jiajun Zhang, Yuheng Jing, Lei Zhang, Hao Zheng, Wenting Zhao, Junyang Lin, Binyuan Hui
Large language models (LLMs) have demonstrated strong coding capabilities but still struggle to solve competitive programming problems correctly in a single attempt.
Execution-based re-ranking offers a promising test-time scaling strategy, yet existing methods are constrained by either difficult test case generation or inefficient random input sampling.
To address this limitation, we propose **Agentic Verifier**, an execution-based agent that actively reasons about program behaviors and searches for highly discriminative test inputs that expose behavioral discrepancies among candidate solutions.
Through multi-turn interaction with code execution environments, the verifier iteratively refines the candidate input generator and produces targeted counterexamples rather than blindly sampling inputs.
We train the verifier to acquire this discriminative input generation capability via a scalable pipeline combining large-scale data synthesis, rejection fine-tuning, and agentic reinforcement learning.
Extensive experiments across five competitive programming benchmarks demonstrate consistent improvements over strong execution-based baselines, achieving up to **+10-15\%** absolute gains in Best@k accuracy.
Further analysis reveals clear test-time scaling behavior and highlights the verifier’s broader potential beyond reranking.
****

Scaling Multi-Agent Environment Co-Design with Diffusion Models
Hao Xiang Li, Michael Amir, Amanda Prorok
The agent-environment co-design paradigm jointly optimises agent policies and environment configurations in search of improved system performance, promising to fundamentally reshape how we deploy multi-agent systems in domains such as warehouse logistics and windfarm management. However, current co-design methods collapse under high dimensional environment design spaces and suffer from sample inefficiency when addressing moving targets inherent to joint optimisation. We address this by developing **Diffusion Co-Design** (DiCoDe), a scalable and sample-efficient co-design framework incorporating two core innovations. We introduce Projected Universal Guidance (PUG), enabling exploration of constraint-satisfying reward-maximising environments, and devise a critic distillation mechanism to transfer knowledge from the reinforcement learning loop to a guided diffuision model. Together, these improvements lead to superior environment-policy pairs when validated on challenging multi-agent co-design benchmarks, for example, exceeding state-of-the art in a warehouse setting with 39% higher rewards and 66% fewer simulation steps.
****

TMS: Trajectory-Mixed Supervision for On-Policy Self Distillation
Rana Shahroz, Zijie Liu, Zhen Tan, Charles Fleming, Tianlong Chen
Reinforcement Learning (RL) and Supervised Fine-Tuning (SFT) are the two dominant paradigms for enhancing Large Language Model (LLM) performance on downstream tasks. While RL generally preserves broader model capabilities (retention) better than SFT, it comes with significant costs: complex reward engineering, instability, and expensive on-policy sampling. In contrast, SFT is efficient but brittle, often suffering from catastrophic forgetting due to $\textbf{Supervision Mismatch}$: the divergence between the model's evolving policy and static training labels. We address this trade-off with $\textbf{Trajectory-Mixed Supervision (TMS)}$, a reward-free framework that approximates the on-policy benefits of RL by creating a dynamic curriculum from the model's own historical checkpoints. TMS minimizes $\textit{Policy-Label Divergence (PLD)}$, preventing the mode collapse that drives forgetting in standard SFT. Experiments across reasoning (MATH, GSM8K) and instruction-following benchmarks demonstrate that TMS effectively shifts the accuracy-retention Pareto frontier. While RL remains the gold standard for retention, TMS significantly outperforms standard and iterative SFT, bridging the g

ap to RL without requiring reward models or verifiers. Mechanistic analysis conf
irms that PLD drift accurately predicts forgetting, and that TMS successfully mi
tigates this drift.

LIMMT: Less Is More for Motion Tracking

Yu Guan, Zekun Qi, Chenghuai Lin, Xuchuan Chen, Wenyao Zhang, Jilong Wang, XinQi
ang Yu, He Wang, Li Yi

We argue that high-quality motion data can steer tracking policies toward better
 optimization trajectories early in training. In this work, we introduce LIMMT (
Less Is More for Motion Tracking). To our knowledge, this is the first data-cent
ric study for physics-based humanoid motion tracking. We go beyond simply removi
ng erroneous clips. We define motion data quality through three dimensions: phys
ics feasibility, diversity, and complexity. We show that training with under 3%
of AMASS yields better tracking performance than training with the full dataset.
 Extensive experiments and analyses validate the effectiveness of our framework.
****

Judgment Operators: A Composition-Invariant Substrate for Multi-Agent Action Spa
ces

Jun Li

As large language models (LLMs) are increasingly composed into heterogeneous mul
ti-agent systems, a fundamental reliability challenge emerges: knowledge and gov
ernance **fragment** across agents, leading to composition-dependent behaviors a
nd linear scaling of violations. Two empirical observations motivate our approac
h: internal correction methods (Reflexion, CRITIC, Self-Refine) fail to enforce
execution-time constraints deterministically, and filter-based methods (LlamaGua
rd) sacrifice task utility without repair. We introduce **Judgment Operators (JO
)**, a decision-time framework implementing four-way intervention semantics (*Al
low, Edit, Escalate, Deny*) via a portable artifact $J=(\mathcal{C},\mathcal{P})
$, enabling minimal repair without modifying agent internals. We establish: (1)
composition-invariant enforcement with constant violation probability, motiv
ated by a necessity lower bound showing no decentralized scheme achieves $O(1)$
violation probability; (2) **sublinear** mistake accumulation via JO-A; and (3)
semantic preservation for code transformation. Programmatically verifiable c
onstraints provide the formal foundation; empirically, robustness extends beyond
 this scope (partial mediation 3--5$\times$ better than theoretical worst-case).
 JO achieves 0\% observed violation rate (vs. 48--68\% baselines), 13.5--20.5\%
zero-shot cross-model transfer where few-shot prompting fails, and provides a **
portable, auditable, and composable** interface for governance and capability in
jection in multi-agent LLM systems.

ArcVQ-VAE: A Spherical Vector Quantization Framework with ArcCosine Additive Mar
gin

Jaeyung Kim, YoungJoon Yoo

Vector Quantized Variational Autoencoder (VQ-VAE) has become a fundamental frame
work for learning discrete representations in image modeling.
However, VQ-VAE models must tokenize entire images using a finite set of codeboo
k vectors, and this capacity limitation restricts their ability to capture rich
and diverse representations.
In this paper, we propose ArcCosine Additive Margin VQ-VAE (ArcVQ-VAE), a novel
vector quantization framework that introduces a spherical angular-margin prior (
SAMP) for the codebook of a conventional VQ-VAE.
The proposed SAMP consists of Ball-Bounded Norm Regularization, which constrains
 all codebook vectors within a time-dependent Euclidean ball, and ArcCosine Addi
tive Margin Loss, which encourages greater angular separability among latent vec
tors.
This formulation promotes more discriminative and uniformly dispersed latent rep
resentations within the constrained space, thereby enabling codebook vectors to
capture richer information and leading to improved codebook utilization.
Experimental results on standard image reconstruction and generation tasks show
that ArcVQ-VAE outperforms baseline models in terms of reconstruction accuracy,

representation diversity, and sample quality.

Multimodal Nested Learning for Decoupled and Coordinated Optimization
Yanglin Feng, Yang Qin, Dezhong Peng, Rui Wang, Xiaomin Song, Peng Hu
Multimodal learning aims to integrate multi-sensor data to exploit their complementary information, embracing a more comprehensive real-world perception and understanding. However, heterogeneous discrepancies across modalities consistently trigger imbalanced multimodal optimization, restricting the joint learning performance. Although existing methods mitigate this issue through optimization modulation and conflict alleviation, they still suffer from entangled optimization and uniform learning pace in conventional monolithic frameworks, limiting the effectiveness of multimodal learning. To address this issue, we propose a novel Multimodal Nested Learning Framework (MoNet), which reformulates the monolithic framework into nested sub-processes, decoupling and coordinating multimodal learning. To achieve this, we present a Decoupled Multimodal Stable Memory block (DMSM) as the outermost nested level, which decouples multimodal learning into independent optimization streams for semantic exploitation across modalities. Additionally, we develop an Adaptive Multimodal Coordinated Fusion block (AMCF), which constitutes the inner nested level. It attempts to coordinate multimodal information integration across multi-timescale nested memories, balancing multimodal fusion. Extensive experimental results on eight datasets across three tasks demonstrate the superiority of MoNet. Code is available at https://github.com/Yangl1nFeng/MoNet.

RTInfer: Real-Time Inference of Multiple DNNs on Edge GPUs
Renjie Li, Tong Sun, Yi Gao, Wei Dong
While edge GPUs are increasingly used for latency-critical DNN tasks, limited resources often fail to meet strict real-time (RT) requirements under concurrent workloads.
Existing preemption and early-exit mechanisms often underutilize GPU resources through single-task queuing and sacrifice excessive accuracy during task bursts.
To address this, we propose RTInfer, a novel system that enables concurrent RT task execution while balancing throughput and accuracy.
RTInfer integrates an accuracy-calibrated lightweight variant co-optimization to generate efficient models, a memory-layout-aware scheduler to mitigate fragmentation during preemption, and an on-demand loading strategy to minimize host-to-GPU latency.
Extensive evaluations demonstrate that RTInfer outperforms state-of-the-art methods by reducing average deadline miss rate (DMR) from 32.8\% to 0\% and improving accuracy by up to 56.5\%.

Rethinking Depth Pruning for Vision Transformers: A Heterogeneity-Aware Perspective
Zhenfeng Su, Kang Zhao, Han Bao, Tao Yuan, Zhongzhe Hu, Xianzhi Yu, Wenxuan Wang
While prior studies have successfully compressed vision Transformers (ViTs) through various pruning techniques, most have concentrated on width pruning to achieve significant reductions in model size. Depth pruning, which removes entire layers from a ViT, is notoriously difficult for accuracy recovery despite its potential to deliver higher speedups, limiting the acceleration achieved by existing joint width-and-depth pruning methods. In this work, we reveal that the failure of existing depth pruning methods lies in their neglect of heterogeneity between different layers, and we introduce HetDPT, a heterogeneity-aware depth pruning method that avoids dimension mismatch. Comprehensive experiments on ImageNet-1K, CIFAR-100, COCO, and ADE20K validate our method: HetDPT achieves a 1.58$\times$ speedup for DeiT-B while maintaining accuracy and a 1.39$\times$ speedup for DeiT-S with nearly no accuracy degradation. Furthermore, when combined with width pruning, HetDPT+ sets a new state-of-the-art record in extreme ViT pruning, enhancing the acceleration ratio from 4.24$\times$ to 5.19$\times$ for the Isomorphic-Pruning-2.6G configuration while maintaining near-lossless accuracy; our code is available at \url{https://github.com/Efficient-AI-for-All/HetDPT}.

Stem: Rethinking Causal Information Flow in Sparse Attention
Lin Niu, Xin Luo, Linchuan Xie, Yifu Sun, Guanghua Yu, Jianchen Zhu, S Kevin Zhou
The quadratic computational complexity of self-attention remains a fundamental bottleneck for scaling Large Language Models (LLMs) to long contexts, particularly during the pre-filling phase. In this paper, we rethink the causal attention mechanism from the perspective of information flow. Due to causal constraints, tokens at initial positions participate in the aggregation of every subsequent token. However, existing sparse methods typically apply a uniform top-k selection across all token positions within a layer, ignoring the cumulative dependency of token information inherent in causal architectures. To address this, we propose Stem, a novel, plug-and-play sparsity module aligned with information flow. First, Stem employs the Token Position-Decay strategy, applying position-dependent top-k within each layer to retain initial tokens for recursive dependencies. Second, to preserve information-rich tokens, Stem utilizes the Output-Aware Metric. It prioritizes high-impact tokens based on approximate output magnitude. Extensive evaluations demonstrate that Stem achieves superior accuracy with reduced computation and pre-filling latency. Code is available at https://anonymous.4open.science/r/stem-254ENLXL.

CVSearch: Empowering Multimodal LLMs with Cognitive Visual Search for High-Resolution Image Perception
Liupeng Li, Haoqian Kang, Zhenyu Lu, Jinpeng Wang, Bin Chen, Ke Chen, Yaowei Wang
High-resolution (HR) image perception presents a key bottleneck for multimodal large language models (MLLMs).
While visual search offers a promising solution, existing methods struggle with the trade-off between coverage and efficiency. Visual expert-assisted search is efficient but prone to blind spots when proposals fail, whereas scan-based search guarantees coverage at the cost of computational redundancy and semantic fragmentation.
To address this dilemma, we introduce CVSearch, a training-free adaptive framework that dynamically schedules search strategies via an Assess-then-Search workflow.
Specifically, CVSearch first invokes expert-assisted search when global information is insufficient, and only triggers a novel semantic-aware scanning mechanism upon failure. Distinct from rigid grid partitioning, this efficient scanning paradigm incorporates Semantic Guided Adaptive Patching to decompose images into semantically consistent regions, effectively mitigating object fragmentation.
Furthermore, we devise a Dynamic Bottom-Up Search strategy driven by a Visual Complexity prior to enable efficient and precise iterative exploration of local details.
Extensive experiments on HR benchmarks demonstrate that CVSearch achieves state-of-the-art accuracy while substantially improving search efficiency.
Code is released at https://github.com/liliupeng28/ICML26-CVSearch.

UniPercept: Towards Unified Perceptual-Level Image Understanding across Aesthetics, Quality, Structure, and Texture
Shuo Cao, Jiayang Li, Xiaohui Li, Yuandong Pu, Kaiwen Zhu, Yuanting Gao, Siqi Luo, Yi Xin, Qi Qin, Yu Zhou, Xiangyu Chen, Wenlong Zhang, Bin Fu, Yu Qiao, Yihao Liu
Multimodal large language models (MLLMs) have achieved remarkable progress in visual understanding tasks such as visual grounding, segmentation, and captioning. However, their ability to perceive perceptual-level image features remains limited. In this work, we present UniPercept-Bench, a unified framework for perceptual-level image understanding across three key domains: Aesthetics, Quality, Structure and Texture. We establish a hierarchical definition system and construct large-scale datasets to evaluate perceptual-level image understanding. Based on this foundation, we develop a strong baseline UniPercept trained via Domain-Adapt

ive Pre-Training and Task-Aligned RL, enabling robust generalization across both Visual Rating (VR) and Visual Question Answering (VQA) tasks. UniPercept outperforms existing MLLMs on perceptual-level image understanding and can serve as a plug-and-play reward model for text-to-image generation. This work defines perceptual-level image understanding in the era of MLLMs and, through the introduction of a comprehensive benchmark together with a strong baseline, provides a solid foundation for advancing perceptual-level multimodal image understanding.

T2AV-Compass: Towards Unified Evaluation for Text-to-Audio-Video Generation

Zhe Cao, Tao Wang, Jiaming Wang, Yanghai Wang, Yuanxing Zhang, Jiahao Wang, Jialu Chen, Miao Deng, Chenxi Liao, Yize Zhang, Yubin Guo, Zhaoxiang Zhang, Jiaheng Liu

Text-to-Audio-Video (T2AV) generation aims to synthesize temporally coherent video and semantically synchronized audio from natural language, yet its evaluation remains fragmented, often
relying on unimodal metrics or narrowly scoped benchmarks that fail to capture cross-modal
alignment, instruction following, and perceptual realism under complex prompts. To address this
limitation, we present T2AV-Compass, a unified benchmark for comprehensive evaluation of
T2AV systems, consisting of 500 diverse and complex prompts constructed via a taxonomy-driven
pipeline to ensure semantic richness and physical plausibility. Besides, T2AV-Compass introduces
a dual-level evaluation framework that integrates objective signal-level metrics for video quality, audio quality, and cross-modal alignment with a subjective MLLM-as-a-Judge protocol for
instruction following and realism assessment. Extensive evaluation of 15 representative T2AV
systems reveals that even the strongest models fall substantially short of human-level realism and
cross-modal consistency, with persistent failures in audio realism, fine-grained synchronization,
instruction following, etc. These results indicate significant improvement room for future models
and highlight the value of T2AV-Compass as a challenging and diagnostic testbed for advancing
text-to-audio-video generation.

Asymptotically Fast Clebsch-Gordan Tensor Products with Vector Spherical Harmonics

YuQing Xie, Ameya Daigavane, Mit Kotak, Tess Smidt

$E(3)$-equivariant neural networks have proven to be extremely effective in a wide range of 3D modeling tasks. A fundamental operation of such networks is the tensor product, which allows interaction between different feature types. Because this operation scales poorly, there has been considerable work towards accelerating this interaction. However, recently [Xie et al. 2025](https://openreview.net/forum?id=EvIwwGYTLc) have pointed out that most speedups come from a reduction in expressivity rather than true algorithmic improvements on computing Clebsch-Gordan tensor products. A modification of Gaunt tensor product ([Luo et al.](https://openreview.net/forum?id=mhyQXJ6JsK)) can give a true asymptotic speedup but is incomplete and misses many interactions. In this work, we provide the first complete algorithm which truly provides asymptotic benefits Clebsch-Gordan tensor products. For full CGTP, our algorithm brings runtime complexity from the naive $O(L^6)$ to $O(L^4\log^2 L)$, close to the lower bound of $O(L^4)$. We first show how generalizing fast Fourier based convolution naturally leads to the previously proposed Gaunt tensor product ([Luo et al.](https://openreview.net/forum?id=mhyQXJ6JsK)). To remedy antisymmetry issues, we generalize from scalar signals to irrep valued signals, giving us tensor spherical harmonics. We prove a gener

alized Gaunt formula for the tensor harmonics. Finally, we show that we only nee d up to vector valued signals to recover the missing interactions of Gaunt tenso r product.

OmniFit: Bridging Modalities via Layer-Adaptive Token Compression for Omnimodal Large Language Models
Zining Wang, Zhihang Yuan, Yingjie Zhai, Wenshuo Li, Han Shu, Ruihao Gong, Jinya ng Guo, Xianglong Liu
Emerging Omni-modal Large Language Models (OmniLLMs) enable real-time interactio n across video, audio, and text but suffer from prohibitive computational costs due to the quadratic complexity of processing continuous streaming inputs. Exist ing token compression strategies remain suboptimal as they typically rely on bia sed modality-centric priors or enforce uniform retention policies, neglecting th e heterogeneity across layers and the critical role of cross-modality alignment. To address these challenges, we propose OmniFit, a training-free framework that decouples interaction profiling from inference execution. OmniFit incorporates Layer-Adaptive Heterogeneity Profiling (LAHP) to dynamically allocate computatio nal budgets based on layer-wise redundancy and modality preferences, preserving tokens according to the characteristics of each layer. Furthermore, we introduce Alignment-Rectified Token Selection (ARTS), a lightweight mechanism that effici ently identifies tokens semantically aligned with cross-modal cues. Extensive ex periments on 3 model series across 10 benchmarks demonstrate that OmniFit establ ishes a new Pareto frontier, retaining 98\% of model performance with only 20\% token usage and achieves up to 2.31$\times$ end-to-end inference speedup and 2.5 $\times$ VRAM saving, significantly outperforming state-of-the-art methods.

PAMD: Structured Adaptive Distances for Bisimulation Representations in Visual R einforcement Learning
Daegyeong Roh, Juho Bae, Han-Lim Choi
Many visual reinforcement learning (RL) algorithms learn representations by matc hing latent distances to a behavioral distance induced by reward and transition similarity. In practice, the choice of the latent distance can strongly affect p erformance: using a fixed, pre-specified global norms (e.g., ℓ_p norms or o ther hand-designed metrics) may be overly restrictive to capture the behavioral distance. In contrast, unconstrained pairwise distances may admit degenerate sol utions that drive the metric loss down without improving the representation. To address this gap, we introduce **PAMD: Pairwise Adaptive Mahalanobis Distance**, which parameterizes a positive-definite, pair-conditioned metric for measuring latent state similarity.

PAMD is a simple plug-in for existing bisimulation-based methods, offering a m ore expressive yet structured alternative to fixed, pre-specified latent distanc es. We empirically validate our method on visual MuJoCo continuous-control tasks , where final performance of several recent bisimulation-based RL algorithms is substantially improved when equipped with the distance we propose.

Modeling Temporal scRNA-seq Data with Latent Gaussian Process and Optimal Transp ort
Mehmet Yigit Balik, Harri Lähdesmäki
Single-cell RNA sequencing provides insights into gene expression at single-cell resolution, yet inferring temporal processes from these static snapshot measure ments remains a fundamental challenge. Current approaches utilizing neural diffe rential equations and flows are sensitive to overfitting and lack careful consid erations of biological variability. In this work, we propose a generative framew ork that models population trends using a latent heteroscedastic Gaussian proces s (GP) approximated by Hilbert space methods. To address the absence of genuine cell trajectories, we leverage an optimal transport (OT) objective that aligns g enerated and observed population distributions. Our method explicitly captures b iological heterogeneity by incorporating cell-specific latent time and cell type conditioning to disentangle temporal asynchrony and trajectories to different c ell types. We demonstrate state-of-the-art performance on complex interpolation

and extrapolation benchmarks and introduce a novel gradient-based strategy for i
nferring perturbation trajectories.
****

BLOCK-EM: Preventing Emergent Misalignment via Latent Blocking
Muhammed Ustaomeroglu, Guannan Qu
Emergent misalignment can arise when a language model is fine-tuned on a narrowl
y scoped supervised objective: the model learns the target behavior, yet also de
velops undesirable out-of-domain behaviors. We investigate a mechanistic approac
h to preventing emergent misalignment by identifying a small set of internal fea
tures that reliably control the misaligned behavior and then discouraging the mo
del from strengthening these features during fine-tuning. Across six fine-tuning
 domains, blocking (i.e., constraining) a fixed set of features achieves up to 9
5\% relative reduction in emergent misalignment with no degradation in model qua
lity or target-task performance. We strengthen validity with disjoint selection/
evaluation splits, multiple independent judges, multiple random seeds for key se
ttings, quality metrics, and extensive ablations demonstrating that the reductio
n in misalignment is specific to the identified mechanism. We also characterize
a limiting regime in which misalignment re-emerges under prolonged fine-tuning,
present evidence consistent with rerouting through alternative features or layer
s, and evaluate modifications that partially restore the misalignment-blocking e
ffect. Overall, our results show that targeted training-time constraints on inte
rnal mechanisms can mitigate emergent misalignment without degrading target-task
 performance.

SOTAlign: Semi-Supervised Alignment of Unimodal Vision and Language Models via O
ptimal Transport
Simon Roschmann, Paul Krzakala, Sonia Mazelet, Quentin Bouniot, Zeynep Akata
The Platonic Representation Hypothesis posits that neural networks trained on di
fferent modalities converge toward a shared statistical model of the world. Rece
nt work exploits this convergence by aligning frozen pretrained vision and langu
age models with lightweight alignment layers, but typically relies on contrastiv
e losses and millions of paired samples.
In this work, we ask whether meaningful alignment can be achieved with substanti
ally less supervision. We introduce a semi-supervised setting in which pretraine
d unimodal encoders are aligned using a small number of image-text pairs togethe
r with large amounts of unpaired data. To address this challenge, we propose SOT
Align, a two-stage framework that first recovers a coarse shared geometry from l
imited paired data using a linear teacher, and then refines the alignment on unp
aired samples via an optimal-transport-based divergence that transfers relationa
l structure without overconstraining the target space. Unlike existing semi-supe
rvised methods, SOTAlign effectively leverages unpaired images and text, learnin
g robust joint embeddings across datasets and encoder pairs, and significantly o
utperforming supervised and semi-supervised baselines.

Demystifying Action Space Design for Robotic Manipulation Policies
Yuchun Feng, Jinliang Zheng, Zhihao Wang, Dongxiu Liu, Jianxiong Li, Jiangmiao P
ang, Tai Wang, Xianyuan Zhan
The specification of the action space plays a pivotal role in imitation-based ro
botic manipulation policy learning, fundamentally shaping the optimization lands
cape of policy learning. While recent advances have focused heavily on scaling t
raining data and model capacity, the choice of action space remains guided by ad
-hoc heuristics or legacy designs, leading to an ambiguous understanding of robo
tic policy design philosophies. To address this ambiguity, we conducted a large-
scale and systematic empirical study, confirming that the action space does have
 significant and complex impacts on robotic policy learning. We dissect the acti
on design space along temporal and spatial axes, facilitating a structured analy
sis of how these choices govern both policy learnability and control stability.
Based on 13,000+ real-world rollouts on a bimanual robot and evaluation on 500+
trained models over four scenarios, we examine the trade-offs between absolute v
s. delta representations, and joint-space vs. task-space parameterizations. Our

large-scale results suggest that properly designing the policy to predict delta actions consistently improves performance, while joint-space and task-space representations offer complementary strengths, favoring control stability and generalization, respectively.

Batched Contextual Reinforcement
Bangji Yang, Hongbo Ma, Jiajun Fan, Ge Liu
Large Language Models (LLMs) employing Chain-of-Thought reasoning achieve strong performance but suffer from excessive token consumption that inflates inference costs. Existing efficiency methods—such as explicit length penalties, difficulty estimators, or multi-stage curricula—either degrade reasoning quality or require complex training pipelines. We introduce **Batched Contextual Reinforcement (BCR)**, a minimalist, single-stage training paradigm that unlocks efficient reasoning through a simple structural modification: training the model to solve N problems simultaneously within a shared context window, rewarded purely by per-instance accuracy. This formulation creates an implicit token budget that yields several key findings: (1) We identify a novel _task-scaling law_: as the number of concurrent problems N increases at inference time, per-problem token usage decreases monotonically---a phenomenon that arises purely at inference, holds for models both before and after training, and is unrelated to accuracy or the training procedure. BCR makes this regime practical by degrading accuracy far more gracefully than baselines as N grows, establishing N as a controllable throughput dimension. (2) BCR challenges the traditional accuracy-efficiency trade-off by demonstrating a "free lunch" phenomenon at standard single-problem (N=1) inference. Across both 1.5B and 4B model families, BCR reduces token usage by 15.8\% to 62.6\% while consistently maintaining or improving accuracy across five major mathematical benchmarks (e.g., +13.3\% on AIME25 for the 4B model). (3) Qualitative analyses reveal emergent self-regulated efficiency, where models autonomously eliminate redundant metacognitive loops without explicit length supervision. (4) Crucially, we empirically demonstrate that implicit budget constraints successfully circumvent the adversarial gradients and catastrophic optimization collapse inherent to explicit length penalties, offering a highly stable, constraint-based alternative for length control. These results establish BCR as a highly practical framework, demonstrating how simple structural training incentives can unlock latent high-density reasoning modes in LLMs.

Re-FORC: Adaptive Reward Prediction for Efficient Chain-of-Thought Reasoning
Renos Zabounidis, Aditya Golatkar, Michael Kleinman, Alessandro Achille, Wei Xia, Stefano Soatto
We propose Re-FORC, an adaptive reward prediction method that, given a query, enables prediction of the expected future rewards as a function of the number of future thinking tokens. Re-FORC trains a lightweight adapter on reasoning models, demonstrating improved prediction with longer reasoning and larger models. Re-FORC enables: 1) early stopping of unpromising reasoning chains, reducing compute by up to 24\% compared to fixed-budget cutoffs, while maintaining accuracy, 2) optimized model and thinking length selection that outperforms the largest model alone---reaching 1.7 percentage points higher peak accuracy while needing up to 12\% less compute to match the largest model's accuracy, 3) adaptive test-time scaling, which increases accuracy by 8.8 percentage points (on average at maximum compute) over confidence-based baselines. Re-FORC allows dynamic reasoning with length control via cost-per-token thresholds while estimating computation time upfront.
****

Training-Free Coverless Multi-Image Steganography with Access Control
Minyeol Bae, Si-Hyeon Lee
Coverless Image Steganography (CIS) hides information without explicitly modifying a cover image, providing strong imperceptibility and inherent robustness to steganalysis. However, existing CIS methods largely lack robust access control, making it difficult to selectively reveal different hidden contents to different authorized users. Such access control is critical for scalable and privacy-sensi

tive information hiding in multi-user settings. We propose MIDAS (Multi-Image Diffusion-based Access-controlled Steganography), a training-free diffusion-based CIS framework that enables multi-image hiding with user-specific access control via latent-level fusion. MIDAS introduces a Random Basis mechanism to suppress residual structural information, together with a theoretical analysis of information leakage, and a Latent Vector Fusion module that reshapes aggregated latents to better align with the diffusion process. Experimental results demonstrate that MIDAS consistently outperforms existing training-free CIS baselines in access control functionality, stego image quality and diversity, robustness to noise, and resistance to steganalysis, establishing a practical and scalable approach to access-controlled coverless steganography.

Mitigating Label Shift in Tabular In-Context Learning via Test-Time Posterior Adjustment

Seunghan Lee

TabPFN has recently gained attention as a foundation model for tabular datasets, achieving strong performance by leveraging in-context learning on synthetic data. However, we find that TabPFN is vulnerable to label shift, often overfitting to the majority class in the training dataset. To address this limitation, we propose DistPFN, the first test-time posterior adjustment method designed for tabular foundation models. DistPFN rescales predicted class probabilities by downweighting the influence of the training prior (i.e., the class distribution of the context) and emphasizing the contribution of the model's predicted posterior, without architectural modification or additional training. We further introduce DistPFN-T, which incorporates temperature scaling to adaptively control the adjustment strength based on the discrepancy between prior and posterior. We evaluate our methods on over 250 OpenML datasets, demonstrating substantial improvements for various TabPFN-based models in classification tasks under label shift, while maintaining strong performance in standard settings without label shift. Code is available at this repository: https://github.com/seunghan96/DistPFN.

Required Spine Optional Limbs: Heterogeneous Federated Learning via Backbone-sharing and Activation-guided Selection

Mingsheng Cao, Hongliang Chen, Ming Hu, Fei Gao, Qiaolong Ding, Wenke Huang, Xiaofei Xie, Junlong Zhou

Although Federated Learning (FL) offers advantages in privacy-preserving for cross-device collaborative learning, its practical deployment remains severely constrained by heterogeneous hardware resources and non-IID (non-independent and identically distributed) data across devices. Sub-model extraction has emerged as a widely adopted strategy for enabling collaborative training among devices with heterogeneous models. However, existing sub-model extraction methods in FL typically rely on coarse-grained stochastic selection or rigid rule-based neuron selection, which severely limits training performance. Specifically, stochastic strategies lead to severe parameter conflicts under non-IID data distributions, while rule-based approaches lack diversity in neuron selection per device, preventing comprehensive parameter optimization. To address this problem, this paper presents a novel sub-model extraction-based FL framework, named SpineFL, which adopts a backbone-sharing mechanism and an activation-guided pruning strategy for sub-model extraction. Specifically, SpineFL decomposes each global model layer into two portions: i) a mandatory backbone shared by all the sub-models to maintain model generalization, and ii) a dynamic portion for sub-model extraction. SpineFL adopts the activation-guided selection strategy to probabilistically select neurons according to their activation frequency from the dynamic portion to generate sub-model, where neurons exhibiting higher historical activation are more likely to be included, thereby simultaneously addressing parameter conflicts while preserving selection diversity. Experimental results demonstrate that compared with state-of-the-art heterogeneous FL methods, SpineFL can achieve up to 3.28% accuracy improvement.

Reward Redistribution for CVaR MDPs using a Bellman Operator on L-infinity

Aneri Muni, Vincent Taboga, Esther Derman, Pierre-Luc Bacon, Erick Delage
Tail-end risk measures such as static conditional value-at-risk (CVaR) are used in safety-critical applications to prevent rare, yet catastrophic events. Unlike risk-neutral objectives, the static CVaR of the return depends on entire trajectories without admitting a recursive Bellman decomposition in the underlying Markov decision process. A classical resolution relies on state augmentation with a continuous variable. However, unless restricted to a specialized class of admissible value functions, this formulation induces sparse rewards and degenerate fixed points. In this work, we propose a novel formulation of the static CVaR objective based on augmentation. Our alternative approach leads to a Bellman operator with: (1) dense per-step rewards; (2) contracting properties on the full space of bounded value functions. Building on this theoretical foundation, we develop risk-averse value iteration and model-free Q-learning algorithms that rely on discretized augmented states. We further provide convergence guarantees and approximation error bounds due to discretization. Empirical results demonstrate that our algorithms successfully learn CVaR-sensitive policies and achieve effective performance-safety trade-offs.
****
On Minimum Depth and Width of Floating-Point Neural Networks for Representing Floating-Point Functions
Sejun Park, Yeachan Park, Geonho Hwang
Research on the expressive power of neural networks has identified the minimum depth and width of neural networks that enable universal approximation and memorization. However, existing results are derived under exact arithmetic and cannot be directly applied to real implementations on computers, which can only use a finite set of numbers and inexact machine operations with round-off errors.
In this work, we study floating-point ReLU networks that have floating-point parameters and use floating-point operations. Specifically, we investigate their minimum depth and width to represent all functions from the set of floating-point vectors $\mathbb F^d$ to the set of floating-point numbers $\mathbb F$. We first show that the minimum depth for representing all functions from $\mathbb F^d$ to $\mathbb F$ is exactly three, where two layers can be sufficient if we consider a smaller domain and/or codomain. We further show that the minimum width for representing all functions from $\mathbb F^d$ to $\mathbb F$ lies between $2d$ and $2d+4$. In addition, if we restrict the domain to non-negative floats, it lies between d and $d+4$, where it can be smaller for a smaller domain, even beyond d. Our results show that the existing results analyzed under exact arithmetic do not extend to the floating-point setup.

HSGG: Training-Free Hierarchical Scene Graph Generation with Geometry-Guided Relation Reasoning
yunzhe Liu, Wenbiao Liu, Lihui Cen, Zhe Qu, Yigang Cen, Yixiong Liang, Yongfang Xie, Shichao Kan
Scene Graph Generation (SGG) connects visual perception with structured reasoning, but is limited by scarce annotations and the long-tailed distribution of relational predicates. Training-free methods based on vision-language models (VLMs) reduce supervision requirements, yet often rely on flat graph structures and produce hallucinated relations. We present HSGG, a training-free framework for open-world Hierarchical Scene Graph Generation, whose inference proceeds in two steps. First, bidirectional hierarchical entity perception combines top-down object expansion with bottom-up attribute reasoning to construct multi-level scene hierarchies capturing part–whole semantics. Second, geometry-guided relation reasoning infers valid relations from these structured entities: geometry-aware relation filtering first prunes spatially implausible object pairs using 2D proximity, depth cues, and object scale, and geometry-grounded contrastive relation decoding then suppresses hallucinated predicates by contrasting predictions from a visually grounded expert against a hallucination-prone geometric prior, ensuring relations are both geometrically consistent and semantically coherent. Experiments show that HSGG generalizes effectively to unseen objects and predicates without training, substantially reduces relational hallucinations, and consistently impr

oves downstream reasoning performance.
****
VisionPulse: Dynamic Visual Sparsity for Efficient Multimodal Reasoning
Hengbo Xu, Shengjie Jin, Yanbiao Ma, Zhiwu Lu
With the rapid advancement of large multimodal models (LMMs), inference-time overhead has become a key bottleneck for real-world deployment.
Existing methods typically prune visual tokens at prefill, assuming the required visual evidence remains static during reasoning.
However, we empirically show that visual evidence is strongly step-dependent: only a sparse subset of visual tokens is critical at each decoding step, and the critical set evolves across reasoning.
Furthermore, we identify a coupled bottleneck where redundant visual context can steer the model toward query-irrelevant regions, lengthening the reasoning trace.
Guided by these insights, we propose **VisionPulse**, a step-wise visual token pruning framework during reasoning.
VisionPulse computes a lightweight visual attention mass to estimate the step-wise retention budget by exploiting its strong positive correlation with LMMs' effective visual token usage and retain only the most critical tokens under this budget.
By enforcing visual sparsity during reasoning, VisionPulse filters redundant visual context while preserving relevant visual evidence, shortening reasoning traces naturally.
Extensive experiments show that VisionPulse only retains 5\% of visual tokens per step with reasoning traces shortened by 11.2\%, while keeping accuracy almost unchanged.
****
Large-Scale Notification Dispatch with Bundle Treatments and Multi-Outcome Uplift Optimization
Jiajing Xu, Yanyun Li, Yongbao Song, Minqin Zhu, Huxiao Ji, Linchuan Li, Cunyi Zhang, Xuanping Li, Kaiqiao Zhan, Yanan Niu
Notification dispatch plays a critical role in large-scale user engagement, involving complex trade-offs across notification timing, presentation style, multiple outcomes, and constraints.
In this paper, we formulate it as a constrained optimization over bundle treatments that jointly specify timing and presentation style, aiming to maximize incremental Daily Active Users (DAU) subject to platform-level budget and device vendor-specific quota constraints.
The problem is challenging due to multi-dimensional, small-effect uplift estimation and large-scale constrained optimization.
To address these challenges, we propose $\textbf{B}$undle $\textbf{U}$plift $\textbf{O}$ptimization with $\textbf{P}$runed $\textbf{L}$agrangian-based $\textbf{R}$elaxation (BUOPLR), a two-stage notification dispatch method that decouples uplift estimation from constrained decision-making.
BUOPLR first learns bundle-level, multi-outcome small uplift through an architecture that captures cross-treatment and cross-outcome relationships, and then performs scalable assignment by restricting the decision space and applying Lagrangian relaxation to a small set of global constraints.
Offline experiments show BUOPLR outperforms state-of-the-art methods, and online A/B tests increase DAU by 0.5\%. BUOPLR is now deployed on Kuaishou, a large-scale short video platform serving over 100 million users daily.

Temporal Self-Rewarding Language Models: Decoupling Chosen-Rejected via Past-Future
Yidong Wang, Xin Wang, Cunxiang Wang, Junfeng Fang, Qiufeng Wang, Jianing Chu, Xuran Meng, Shu-Xun Yang, Andrew Zhuoer Feng, Libo Qin, Wei Ye, Shikun Zhang
Self-Rewarding Language Models propose an architecture in which the Large Language Models(LLMs) both generates responses and evaluates its own outputs via LLM-as-a-Judge prompting, dynamically improving its generative capabilities through iterative Direct Preference Optimization (DPO). However, our analysis reveals a c

ritical limitation in existing self-rewarding paradigms: the synchronized improv
ement of chosen and rejected responses progressively narrows the representationa
l difference between contrasting samples, undermining effective preference learn
ing. We propose Temporal Self-Rewarding Language Models that strategically coord
inate past, present, and future model generations to sustain learning signals. O
ur dual-phase framework introduces: (1) Anchored Rejection - fixing rejected res
ponses using the past initial model's outputs and (2) Future-Guided Chosen - dyn
amically curating chosen samples using next-generation model predictions. Extens
ive experiments across three model families (Llama, Qwen, Mistral) and different
 model sizes (Llama3B/8B/70B) demonstrate significant improvements when trained
with our method compared to self-rewarding using same computation resources. For
 example, Llama3.1-8B reaches a 29.44 win rate on AlpacaEval 2.0 with our method
, outperforming the self-rewarding baseline (19.69) by 9.75. Notably, our method
 also demonstrates superior out-of-distribution generalization across mathematic
al reasoning (GSM8K), knowledge-based QA (ARC, TruthfulQA), and code generation
(HumanEval) tasks, even though we do not specifically collect such training data
. The generality of our temporal strategy is further validated by its benefits w
hen extended to online reinforcement learning settings on mathematical reasoning
 tasks.
****

Post-Training Language Models for Crosslingual Consistency
Tianyu Liu, Jirui Qi, Mrinmaya Sachan, Ryan Cotterell, Raquel Fernández, Arianna
 Bisazza
Language models often respond inconsistently to translation-equivalent prompts a
cross languages, undermining the reliability of multilingual systems. To quantif
y this, we give an information-theoretic definition of crosslingual consistency
as a divergence bound between a model’s response distribution and its round-trip
 pushforward across languages. We then introduce penalized consistency optimizat
ion (PCO), a post-training procedure that couples this divergence with a Kullbac
k–Leibler penalty to a fixed reference language model. Because direct optimizati
on of PCO requires expensive on-policy roll-outs, we propose a tractable surroga
te, direct consistency optimization (DCO), which can be optimized off-policy. Ac
ross diverse language models and 26 languages, DCO significantly improves crossl
ingual consistency, outperforms existing methods, and enables targeted alignment
 of low-resource languages.

WF-Bench: A Benchmark for Neural-Network WaveFunction Expressivity and Scaling L
aws
Lixing Zhang, Guijing Duan, Di Luo
We present a comprehensive benchmarking dataset and empirical scaling law
analysis for neural network wavefunctions by matching them to a wide spectrum of
famous many body target wavefunctions. The dataset, WF-Bench, spans multiple dis
tinct regimes of strongly correlated quantum matter, including topological state
s, Wigner
crystals, and superconducting wavefunctions, providing a diverse and challenging
 test
bed for neural network wavefunction expressivity. We introduce a systematic and
reproducible benchmarking protocol for target wavefunction matching, enabling co
nsistent
performance evaluation across different neural network wavefunction architecture
s.
By using wavefunction fidelity as the uniform metric, we discover empirical scal
ing laws that characterize how
representability depends on system size and key model parameters, including numb
er of determinant and model depth. By applying our benchmark protocol on Psiform
er and Ferminet, we show that WF-Bench establishes a unified dataset driven fram
ework for evaluating and
comparing neural network wavefunctions and for guiding the design of future arch
itectures.

BioProBench: A Corpus and Benchmark for Biological Protocol Reasoning in Autonomous Science
Yuyang Liu, Liuzhenghao Lv, Xiancheng Zhang, Jingya Wang, Li Yuan, Yonghong Tian
The realization of autonomous scientific experimentation is currently limited by LLMs' struggle to grasp the strict procedural logic and accuracy required by biological protocols. To address this fundamental challenge, we present BioProBench, a comprehensive resource for procedural reasoning in biology. BioProBench is grounded in BioProCorpus, a foundational collection of 27,000 human-written protocols. From this corpus, we systematically constructed a dataset of over 550,000 task instances, offering both a large-scale training resource and a rigorous benchmark with novel metrics. Evaluating 10 mainstream LLMs, we find that while general comprehension is high, performance drops significantly on tasks demanding deep reasoning, quantitative precision, and safety awareness.
To demonstrate the value of BioProCorpus in mitigating these issues, we developed \textbf{ProAgent}, grounded in our corpus, ProAgent substantially advances the state-of-the-art. Code and data are available at: https://github.com/YuyangSunshine/bioprotocolbench and https://huggingface.co/datasets/BioProBench/BioProBench .

How Language Models Process Negation
Zhejian Zhou, Tianyi Zhou, Robin Jia, Jonathan May
We study how Large Language Models (LLMs) process negation mechanistically.
First, we establish that even though open-weight models often provide wrong answers to questions involving negation, they do possess
internal components that process negation correctly.
Their poor accuracy is due to late-layer attention behavior that promotes simple shortcuts; ablating those attention modules greatly improves accuracy on negation-related questions.
Second, we uncover how models process negation.
We consider two hypotheses: models could use attention heads that attend to the phrase being negated and suppress related concepts, or they could directly construct a representation of the entire negative phrase (e.g., representing "not gas" as a vector that promotes liquids and solids).
We apply a range of observational and causal interpretability techniques on Mistral-7B and Llama-3.1-8B to show that models implement both mechanisms, with the "constructive" mechanism being more prominent.
Combined, our work deepens the understanding of LLMs' internals,
highlighting construction-dominant computations and the coexistence of competing mechanisms within LLMs.

TiME: Test-Time Mixture-of-Experts Routing via Asymmetric CO-Optimal Transport for Continual Test-Time Adaptation
Tianlun Liu, Zhiliang Tian, Zhen Huang, Tianle Liu, Xingzhi Zhou, Feng Liu, Dongsheng Li
Large language models usually face continuous domain shifts during testing, which degrade performance on unseen shifting domains.
So, researchers propose continual test-time adaptation (CTTA) to adapt to evolving testing domains while preserving knowledge of previous domains, making adaptability-stability (A-S) balance.
Existing CTTA methods are constrained by dense base models that encode knowledge from all domains into a global model, hardly achieving the A-S balance.
We observe that the model sparsity of mixture-of-experts (MoE) models is better for achieving A–S balance than dense models.
In CTTA, however, MoE faces difficulty in (1) correctly routing samples from unseen shifting domains and (2) capturing domain-level shifts.
In this paper, we propose test-time mixture-of-experts routing (TiME) via asymmetric co-optimal transport (As-COOT): we model MoE routing in CTTA as a test-time allocation problem via COOT.
To ensure reliable routing, we propose a semantic space alignment to align sample-expert distributions via bidirectional contrastive learning.

To address COOT’s limitations in CTTA, we propose As-COOT, relaxing sample-side constraints while enforcing expert-side constraints to ensure noise robustness a nd balance expert load. Experiments show TiME outperforms baselines.
****
Beyond Binary: Continuous State Optimization with Graph-Structured Objectives
Corinna Cortes, Yishay Mansour, Mehryar Mohri
Large-scale learning systems often face the challenge of balancing multiple, potentially competing objectives, such as fairness, accuracy, and latency. While recent work has formalized this as an optimization problem over binary states, many real-world control parameters---such as fairness thresholds, diversity mixing rates, or resource budgets---are continuous. In this work, we extend the framework to *continuous state spaces*. We model the problem as minimizing a sum of linear objectives subject to *movement costs* that penalize system instability. We capture the local structure of the objectives using a *dependency graph* (or factor graph), where each objective is determined by a subset of the state attributes. To address the tension between exploration and stability, we propose *Lazy Graph-LinUCB*, an algorithm that performs lazy updates to minimize switching costs while maintaining near-optimal regret. Beyond stability, we introduce three advanced mechanisms to exploit the underlying graph structure: (1) an *asynchronous* update schedule that eliminates synchronization overhead in sparse graphs; (2) an *adaptive* algorithm that learns the graph structure from data; and (3) a *joint estimator* that leverages data sharing among correlated objectives to significantly tighten regret bounds. Empirically, we demonstrate that these structural exploitations reduce movement costs by more than a factor of three in heterogeneous systems while maintaining similar cumulative losses.

CoLA: Cross-Modal Low-rank Adaptation for Multimodal Downstream Tasks
Wish Suharitdamrong, Tony Alex, Muhammad Awais, Sara Atito
Foundation models have revolutionized AI, but adapting them efficiently for mult imodal tasks, particularly in dual-stream architectures composed of unimodal enc oders, such as DINO and BERT, remains a significant challenge. Parameter-Efficie nt Fine-Tuning (PEFT) methods like Low-Rank Adaptation (LoRA) enable lightweight adaptation, yet they operate in isolation within each modality, limiting their ability in capturing cross-modal interactions. In this paper, we take a step in bridging this gap with Cross-Modal Low-Rank Adaptation (CoLA), a novel PEFT fram ework that extends LoRA by introducing a dedicated inter-modal adaptation pathwa y alongside the standard intra-modal one. This dual-path design enables CoLA to adapt unimodal foundation models to multimodal tasks effectively, without interf erence between modality-specific and cross-modal learning. We evaluate CoLA acro ss a range of vision-language (RefCOCO, RefCOCO+, RefCOCOg) and audio-visual (AV E, AVS) benchmarks, where it consistently outperforms LORA, achieving a relative gain of around 3\% and 2\%, respectively, while maintaining parameter efficienc y. Notably, CoLA enables the first multi-task PEFT framework for visual groundin g, bridging a key gap in efficient multimodal adaptation. Code is available at h ttps://github.com/peterwisu/CoLA

SPATIA: Multimodal Generation and Prediction of Spatial Cell Phenotypes
Zhenglun Kong, Mufan Qiu, John Boesen, xiang lin, Sukwon Yun, Tianlong Chen, Man olis Kellis, Marinka Zitnik
Understanding how cellular morphology, gene expression, and spatial context join tly shape tissue function is a central challenge in biology. Image-based spatial transcriptomics technologies now provide high-resolution measurements of cell i mages and gene expression profiles, but existing methods typically analyze these modalities in isolation or at limited resolution.
We address the problem by introducing SPATIA, a multi-level generative and predi ctive model that learns unified, spatially aware representations by fusing morph ology, gene expression, and spatial context from the cell to the tissue level. S PATIA also incorporates a spatially conditioned generative framework with confid

ence-aware OT reweighting and morphology-profile alignment for modeling target-state morphology distributions. Specifically, we propose a confidence-aware flow matching objective that reweights weak optimal-transport pairs based on uncertainty. We further apply morphology-profile alignment to encourage biologically meaningful image generation, enabling the modeling of microenvironment-dependent phenotypic transitions. We assembled a multi-scale dataset consisting of 25.9 million cell-gene pairs across 17 tissues. We benchmark SPATIA against 18 models across 12 tasks, spanning categories such as phenotype generation, annotation, clustering, gene imputation, and cross-modal prediction. SPATIA achieves improved performance over state-of-the-art models, improving generative fidelity by 8\% and predictive accuracy by up to 3\%.

InnoEval: On Research Idea Evaluation as a Knowledge-Grounded, Multi-Perspective Reasoning Problem
Shuofei Qiao, Yunxiang Wei, Xuehai Wang, Bin Wu, Boyang XUE, Ningyu Zhang, Hossein A. Rahmani, Wang Yanshan, Qiang Zhang, Keyan Ding, Jeff Z. Pan, Huajun Chen, Emine Yilmaz
The rapid evolution of Large Language Models has catalyzed a surge in scientific idea production, yet this leap has not been accompanied by a matching advance in idea evaluation. The fundamental nature of scientific evaluation needs knowledgeable grounding, collective deliberation, and multi-criteria decision-making. However, existing idea evaluation methods often suffer from narrow knowledge horizons, flattened evaluation dimensions, and the inherent bias in LLM-as-a-Judge. To address these, we regard idea evaluation as a knowledge-grounded, multi-perspective reasoning problem and introduce **InnoEval**, a deep innovation evaluation framework designed to emulate human-level idea assessment. We apply a heterogeneous deep knowledge search engine that retrieves and grounds dynamic evidence from diverse online sources. We further achieve review consensus with an innovation review board containing reviewers with distinct academic backgrounds, enabling a multi-dimensional decoupled evaluation across multiple metrics. We construct comprehensive datasets derived from authoritative peer-reviewed submissions to benchmark InnoEval. Experiments demonstrate that InnoEval can consistently outperform baselines in point-wise, pair-wise, and group-wise evaluation tasks, exhibiting judgment patterns and consensus highly aligned with human experts.

Simple Policy Gradients for Reasoning with Diffusion Language Models
Anthony Zhan
Diffusion large language models (dLLMs) represent a promising alternative to autoregressive LLMs; however, the lack of effective post-training techniques, including reinforcement learning (RL), remains a key challenge for dLLMs, especially for downstream applications. Existing approaches often rely on a sequence-level view that requires biased likelihood approximations. In this work, we propose Amortized Group Relative Policy Optimization (AGRPO), a policy gradient algorithm that leverages the Markovian nature of dLLM generation, optimizing individual denoising steps rather than full sequences. Our approach improves the theoretical alignment between training and inference policies and also admits efficient, unbiased gradient updates via a novel timestep estimation scheme. We demonstrate AGRPO's effectiveness on different math and reasoning tasks, achieving absolute accuracy gains of +59.4\% and +69.7\% on Countdown and Sudoku over the base LLaDA model, exceeding comparable methods such as diffu-GRPO.
****

PCRNet: Phase-aware Complex Refinement Network for EEG-based Auditory Attention Decoding
Xiran Chen, Xiaoke Yang, Jian Zhou, Zhao Lv, Cunhang Fan
Auditory attention decoding (AAD) based on Electroencephalography (EEG) aims to identify the attended speaker in multi-speaker environments. However, existing methods typically overlook the crucial phase information of EEG signals, which limits their ability to distinguish structured neural patterns from random noise in the frequency domain and hinders robust decoding. To address these issues, this paper proposes a Phase-aware Complex Refinement Network (PCRNet) for AAD, whic

h consists of a Temporal Context Calibration (TCC) module and a Dual-Domain Inte
gration (DDI) module. Specifically, the TCC module captures long-range temporal
dependencies through multi-scale temporal attention mechanism, while the DDI mod
ule employs a phase-guided spectral filtering strategy to dynamically suppress n
oise-dominated frequencies and refine the real and imaginary components separate
ly. This design enables effective phase recalibration and enhances the discrimin
ability of target features in the complex domain. Experimental results on three
public datasets demonstrate that PCRNet outperforms state-of-the-art (SOTA) meth
ods, particularly under challenging ultra-short 0.1-second windows. Code is avai
lable at: https://github.com/SunshineGreeny/PCRNet.

Towards Hierarchy–Uniformity Equilibrium: Recovering Semantic Depth in Hypergrap
h Contrastive Learning
Ruiting Zhao, Ming Li, Lixin Cui, Lu Bai, Feilong Cao, Ke Lv, Pietro Lio
Hypergraph contrastive learning is an effective paradigm for representation lear
ning on higher-order relational data, yet existing methods largely ignore that h
yperedges link nodes with multi-level semantics. Standard contrastive objectives
 emphasize instance discrimination via hyperspherical uniformity and tend to pus
h embeddings apart in an indiscriminate manner. We show that this leads to a *Hi
erarchy–Uniformity Conflict*, whose geometric manifestation is *Semantic Flatten
ing*, where the semantic depth of hyperedges collapses into a nearly flat cloud
of instances. To address this issue, we introduce **HyperDepth**, a hypergraph c
ontrastive learning framework that moves representations towards a hierarchy–uni
formity equilibrium by jointly coordinating spectral and geometric signals. Hype
rDepth employs a decoupled spectral encoding scheme with adaptive gating so that
 high-frequency components focus on local instance discrimination while low-freq
uency components capture global hierarchical structure. On top of this, an energ
y-based hierarchical alignment module attaches a learnable prototype tree to the
 representation space and minimizes an interpretable energy functional to recove
r the semantic depth of hyperedges. Theoretically, under a mild frequency-separa
tion assumption, we show that the local contrastive and global hierarchical obje
ctives operate on orthogonal spectral components and admit equilibrium embedding
s that preserve semantic depth while still retaining instance-level discriminati
on. Experiments on 15 hypergraph datasets and 17 supervised and self-supervised
baselines, spanning homophilic and heterophilic regimes, show that HyperDepth at
tains strong performance with the best average rank.

Data-driven Mixed Integer Optimization through Probabilistic Multi-variable Bran
ching
Yanguang Chen, Wenzhi Gao, Wanyu Zhang, Dongdong Ge, Huikang Liu, Yinyu Ye
This paper introduces Probabilistic Multi-Variable Branching (PMVB), a simple an
d effective technique for accelerating mixed-integer optimization using data-dri
ven machine learning models. At its core, PMVB employs a multi-variable branchin
g procedure that partitions the feasible region via data-driven hyperplanes and
requires only two lines of code to implement. Moreover, PMVB is model-agnostic a
nd compatible with a wide range of machine learning models. Leveraging tools fro
m statistical learning theory, we develop interpretable hyperparameter selection
 strategies and propose several extensions to further enhance performance. We ev
aluate PMVB by integrating it into state-of-the-art MIP solvers and conducting e
xperiments on both classical benchmark datasets and real-world instances. The re
sults demonstrate the effectiveness of PMVB in improving MIP-solving efficiency.

Escaping Whack-a-Mole: Optimizing Documentation as Repo-Specific Playbooks for C
oding Agents
Yutong Cheng, Haifeng Chen, Wenchao Yu, Xujiang Zhao, Peng Gao, Wei Cheng
As large language models increasingly function as autonomous coding agents, code
 documentation should be designed not for human readability, but for agent execu
tability — serving as repo-specific playbooks that specify precise behaviors age
nts can follow. We formulate agent-oriented documentation generation as a black-
box optimization problem over the documentation space, where quality is defined

solely by downstream code correctness. A central challenge for conventional LLM refinement methods is output coupling—program entities are interdependent, and refining the documentation of one entity can invalidate its callers, resulting in a persistent whack-a-mole phenomenon during inference-time scaling. We propose DocSearch, a dependency-guided bi-level search framework that systematically exploits test-time feedback. The outer level conducts a priority search over the program-entity dependency DAG, enforcing a callee-before-caller refinement order to prevent downstream interference. The inner level performs a beam search over documentation refinements, using diversified error message sampling from self-generated unit tests to better exploit diagnostic signals and escape local optima. On DevEval+, DocSearch achieves 90.7\% solve rate with GPT-4o, outperforming the strongest baseline by 32.6\%. Cross-language experiments further demonstrate that optimized documentation transfers effectively to different target programming languages. Code is available at https://github.com/ccsnow127/docsearch.

Mean Flow Policy Optimization

Xiaoyi Dong, Xi Sheryl Zhang, Jian Cheng

Diffusion models have recently emerged as expressive policy representations for online reinforcement learning (RL). However, their iterative generative processes introduce substantial training and inference overhead. To overcome this limitation, we propose to represent policies using MeanFlow models, a class of few-step flow-based generative models, to improve training and inference efficiency over diffusion-based RL approaches. To promote exploration, we optimize MeanFlow policies under the maximum entropy RL framework via soft policy iteration, and address two key challenges specific to MeanFlow policies: action likelihood evaluation and soft policy improvement. Experiments on MuJoCo, DeepMind Control Suite and HumanoidBench benchmarks demonstrate that our method, Mean Flow Policy Optimization (MFPO), achieves performance comparable to or exceeding current diffusion-based baselines while considerably reducing training and inference time. Our code is available at https://github.com/dongxiaoyi-xyz/MFPO.

End-to-End Compression for Tabular Foundation Models

Guri Zabërgja, Rafiq Kamel, Arlind Kadra, Christian Frey, Josif Grabocka

The long-standing dominance of gradient-boosted decision trees for tabular data has recently been challenged by in-context learning tabular foundation models. In-context learning methods fit and predict in one forward pass without parameter updates by leveraging the training data as context for predicting on query test points.

While recent tabular foundation models achieve state-of-the-art performance, their transformer architecture based on the attention mechanism has quadratic complexity regarding dataset size, which in turn increases the overhead on training and inference time, and limits the capacity of the models to handle large-scale datasets. In this work, we propose TACO, an end-to-end tabular compression model that compresses the training dataset in a latent space. We test our method on the TabArena benchmark, where our proposed method is up to 94x faster in inference time, while consuming up to 97% less memory compared to the state-of-the-art tabular Transformer architecture, all while retaining performance without significant degradation. Lastly, our method not only scales better with increased dataset sizes, but it also achieves better performance compared to other baselines.

Seeing is Understanding: Unlocking Causal Attention into Modality-Mutual Attention for Multimodal LLMs

Wei-Yao Wang, Zhao Wang, Helen Suzuki, Yoshiyuki Kobayashi

Recent Multimodal Large Language Models (MLLMs) have demonstrated significant progress in perceiving and reasoning over multimodal inquiries, ushering in a new research era for foundation models. However, vision-language misalignment in MLLMs has emerged as a critical challenge, where the textual responses generated by these models are not factually aligned with the given text-image inputs. Existing efforts to address vision-language misalignment have focused on developing specialized vision-language connectors or leveraging visual instruction tuning fro

m diverse domains. In this paper, we tackle this issue from a fundamental yet unexplored perspective by revisiting the core architecture of MLLMs. Most MLLMs are typically built on decoder-only LLMs consisting of a causal attention mechanism, which *limits the ability of the earlier modalities (e.g., images) to incorporate information from the latter modalities (e.g., text)*. To address this problem a MLLM that unlocks causal attention into our proposed modality-mutual attention (MMA) to enable image tokens to attend to text tokens. This simple yet effective design allows MMA to achieve state-of-the-art performance in 12 multimodal understanding benchmarks (**+6.2\% on average across 3 LLMs backbones**) without introducing additional parameters. Our MMA design is intended to be generic, allowing for applications across various modalities, and scalable to accommodate diverse multimodal scenarios.

Width Independent Bounds for the Local Lipschitz Constant of Deep Neural Networks at Random Initialization and after Lazy Training

Apostolos Evangelidis, Felix Krahmer

A plethora of recent works has shown that for wide, overparameterized neural networks, training with Stochastic Gradient Descent (SGD) often leads to interpolation of the training data without sacrificing generalization performance. A key parameter that is not only closely connected to generalization properties, but is also closely tied to other desiderata such as robustness and resistance to adversarial perturbations is the Lipschitz constant of the neural network. While empirically, the Lipschitz constant has been shown not to increase with network width, theoretical findings only provide bounds with logarithmic growth in the width and only for the random initialization of ReLU-networks. In this work, we close this gap for neural networks with smooth activations by showing that, both at random initialization and throughout lazy training, the local Lipschitz constant of deep neural networks does not increase with network width. More precisely, we establish novel non-asymptotic (finite width) upper bounds and corroborate them by numerical experiments.

****

Gradient Preconditioning for Efficient and Reliable Reward-Guided Generation

Jisung Hwang, Minhyuk Sung

We propose a gradient preconditioning method that makes reward-guided generation with one-step generative models both efficient and reliable. Test-time noise optimization can unlock substantially better reward-guided generations from pretrained generative models, but it is prone to reward hacking that degrades quality and is often too slow for practical use. We precondition reward gradients by projecting them onto a carefully designed white Gaussian noise feasible set, a compact spectral set with blockwise norm constraints that tightly captures the statistics and spatial uncorrelatedness of white Gaussian noise. This preconditioning reshapes each gradient update into a noise-aligned direction, driving faster and more effective reward ascent while preventing reward hacking. The projection is closed-form and matches the $\mathcal{O}(N \log N)$ complexity of FFT, adding negligible overhead in practice. In experiments on FLUX with four reward models, our approach reaches a comparable Aesthetic Score using only 30\% of the wall-clock time required by the state-of-the-art regularization-based method.

MDGMIX: Boundary-Aware Subgraph Mixing for Multi-Domain Graph Pre-Training

Ziyu Zheng, Yaming Yang, Ziyu Guan, Wei Zhao, Xinyan Huang

Multi-domain graph pre-training is a crucial step in constructing foundational graph models with cross-domain generalization capabilities. However, existing methods predominantly rely on jointly training all source domain graphs, resulting in high computational costs. Furthermore, it remains unclear whether all source domain graph data contribute equally to effective transfer. This paper empirically reveals significant data redundancy in multi-domain graph pre-training. Based on this finding, we propose the Multi-domain Graph Pre-training Framework, MDGMIX, which combines boundary-aware subgraph mixing with hierarchical discrimination. By selecting boundary nodes to construct challenging mixed-domain subgraphs, MDGMIX employs coarse-grained domain discrimination and fine-grained domain dec

omposition losses to decouple shared patterns from domain-specific patterns. Dur
ing adaptation, MDGMIX employs a lightweight prompt weighting mechanism to trans
fer source domain knowledge. Extensive experiments demonstrate that MDGMIX consi
stently outperforms strong baselines in few-shot classification tasks while exhi
biting superior time and memory efficiency. The code is available at: https://gi
thub.com/zhengziyu77/MDGMIX

Asymptotic Optimality of the High-Dimensional Gaussian Mechanism and Improved Lo
w-Dimensional Mechanisms for Differential Privacy
Yu Wei, Alexander Bienstock, Antigoni Polychroniadou
The additive noise mechanism is a foundational tool for differential privacy (DP
) of T-dimensional real-valued vector queries. The Gaussian mechanism, utilizi
ng Gaussian noise, is the mostly widely used such mechanism, due to its simplici
ty and strong privacy guarantees. In this work, we provide justification for thi
s choice, showing that as the dimension $T\to\infty$, no additive-noise mechanis
m can asymptotically improve on the Gaussian mechanism's privacy--utility tradeo
ff for the strong privacy settings typically used. We also develop a new family
of **Spherical Generalized Gamma** DP mechanisms, which contains both the Gaussi
an mechanism and the recently studied ℓ_2 mechanism (Joseph \emph{et al.},
ICML 2025). We identify members of this family that outperform both the Gaussian
 and ℓ_2 mechanisms in certain low-dimensional settings, and show tight com
position of all mechanisms in this family, answering an open question of Joseph
\emph{et al.}~regarding the ℓ_2 mechanism.
****

Expressivity-Efficiency Tradeoffs for Hybrid Sequence Models
John Cooper, Ilias Diakonikolas, Mingchen Ma, Frederic Sala
Hybrid sequence models—combining Transformer and state-space model layers—seek t
o gain the expressive versatility of attention as well as the computational effi
ciency of state-space model layers. Despite burgeoning interest in hybrid models
, we lack a basic understanding of the settings where—and underlying mechanisms
through which—they offer benefits over their constituent models. In this paper,
we study this question, focusing on a broad family of core synthetic tasks. For
this family of tasks, we prove the existence of fundamental limitations for non-
hybrid models. Specifically, any Transformer or state-space model that solves th
e underlying task requires either a large number of parameters or a large workin
g memory. On the other hand, for two prototypical tasks within this family—namel
y selective copying and associative recall—we construct hybrid models of small s
ize and working memory that provably solve these tasks, thus achieving the best
of both worlds. Our experimental evaluation empirically validates our theoretica
l findings. Importantly, going beyond the settings in our theoretical analysis,
we empirically show that learned—rather than constructed—hybrids outperform non-
hybrid models with up to $6 \times$ as many parameters. We additionally demonstr
ate that hybrid models exhibit stronger length generalization and out-of-distrib
ution robustness than non-hybrids.

Decentralized Instruction Tuning: Conflict-Aware Splitting and Weight Merging
MINSIK CHOI, Geewook Kim
Instruction tuning aligns large language models, including multimodal ones, with
 diverse user intents, but scaling to heterogeneous mixtures is hindered by grad
ient interference and bandwidth-heavy synchronization. We ask whether these two
bottlenecks can be addressed jointly by training parts of the mixture independen
tly and reconciling them once in parameter space. We develop a local quadratic t
heory inside a shared flat basin that yields three results: weight merging produ
ces a curvature-weighted variance reduction; PCA-aligned conflict splitting maxi
mizes this gain along high-curvature directions; and merging additionally acts a
s spectral filtering with implicit norm regularization. These results directly m
otivate **MERIT**, a decentralized merge-ready instruction-tuning pipeline that
estimates dataset-level gradient conflicts, partitions the mixture along the top
 PCA conflict axes, fine-tunes each partition independently with no inter-partit
ion communication, and merges once via token-weighted averaging. On Qwen2.5-VL-3

B with 136 Vision-FLAN tasks, MERIT improves the 8-benchmark average from 54.3 (joint training) to 57.0. The same recipe scales to a 7B model on a 1.6M-example, 176-source mixture—matching or exceeding centralized joint training with minima l cost overhead—and transfers to text-only FLAN. Our code is available at [https ://github.com/naver-ai/merit](https://github.com/naver-ai/merit).

Generative Online Reinforcement Learning
Chubin Zhang, Zhenglin Wan, Feng Chen, Fuchao Yang, Lang Feng, Yaxin Zhou, Xingr ui Yu, Yang You, Ivor Tsang, Bo An
Reinforcement learning (RL) faces a persistent tension: policies that are stable to optimize (e.g., Gaussians) are often too simple to represent the multimodal action distributions required for complex control. Conversely, expressive genera tive policies—such as diffusion and flow matching—can be difficult to optimize i n online RL due to intractable likelihoods and gradients propagating through lon g sampling chains. We address this tension with a key structural principle: *dec oupling optimization from generation*. Building on this, we introduce GoRL (Gene rative Online Reinforcement Learning), an algorithm-agnostic framework that trai ns expressive policies from scratch by confining policy optimization to a tracta ble latent space while delegating action synthesis to a conditional generative d ecoder. Using a two-timescale alternating schedule and anchoring decoder refinem ent to a fixed prior, GoRL enables stable optimization while continuously expand ing expressiveness. Empirically, GoRL consistently outperforms unimodal and gene rative baselines across diverse continuous-control tasks. Notably, GoRL achieves returns exceeding **870** on HopperStand, more than $3\times$ the strongest bas eline; on high-dimensional humanoid tasks, it further outperforms the strongest non-GoRL baseline by over an order of magnitude.

Coevolutionary Continuous Discrete Diffusion: Make Your Diffusion Language Model a Latent Reasoner
Cai Zhou, Chenxiao Yang, Yi Hu, Chenyu Wang, Chubin Zhang, Muhan Zhang, Lester M ackey, Tommi Jaakkola, Stephen Bates, Dinghuai Zhang
Diffusion language models, especially masked discrete diffusion models, have ach ieved great success recently. While there are some theoretical and primary empir ical results showing the advantages of latent reasoning with looped transformers or continuous CoT, continuous diffusion models typically underperform their dis crete counterparts. In this paper, we argue that diffusion language models do no t necessarily need to be in the discrete space. In particular, we prove that con tinuous diffusion models have stronger expressivity than discrete diffusions and looped transformers. We attribute the contradiction between the theoretical exp ressiveness and empirical performance to their practical trainability: while con tinuous diffusion provides intermediate supervision that looped transformers lac k, they are harder to generate and decode tokens in the continuous representatio n space compared with discrete states. We therefore propose **C**oevolutionary * *C**ontinuous **D**iscrete **D**iffusion (CCDD), which defines a joint multimoda l diffusion process on the union of a continuous representation space and a disc rete token space, leveraging a single model to simultaneously denoise in the joi nt space. By combining two modalities, CCDD is expressive with rich semantics in the latent space, as well as good trainability and sample quality with the help of explicit discrete tokens. We also propose effective architectures and advanc ed training/sampling techniques for CCDD, which reveals strong empirical perform ance in extensive language modeling experiments on real-world tasks.
****

Unpaired Visual Editing with Self-Consistent Flow Matching
Yoad Tewel, Yuval Atzmon, Gal Chechik, Lior Wolf
Modern generative models possess a deep understanding of visual content, yet tra ining them for image editing typically requires massive datasets of paired examp les. This limits scalability, especially for video editing where collecting pair ed data is prohibitively expensive. We propose a general framework for unpaired training of flow matching editing models. It leverages the base model's knowledg e without any external signal. Our approach pairs instruction-following cues ext

racted from the frozen model with cycle-consistency for structure preservation. To make this tractable, we propose to route gradients from downstream losses over clean predictions to noisy training states. We demonstrate state-of-the-art results on challenging data-scarce image and video editing scenarios. Extensive evaluations and user studies show that our method effectively generalizes to unseen domains and outperforms supervised baselines trained on millions of samples. Analysis reveals that our gradient routing bridges the train-inference gap, and extracting semantic cues from a base model provides a robust training signal that obviates the need for external reward models.

Matroid Algorithms Under Size-Sensitive Independence Oracles

Kiarash Banihashem, MohammadTaghi Hajiaghayi, Mahdi JafariRaviz, Danny Mittal

The standard oracle model for matroid algorithms assumes that each independence query can be answered in constant time, regardless of the size of the queried set. While this abstraction has underpinned much of the theoretical progress in matroid optimization, it masks the true computational effort required by these algorithms. In particular, for natural and widely studied classes such as graphic matroids, even a single independence query can require work linear in the size of the set, making the constant-time assumption implausible. We address this gap by introducing a size-sensitive cost model where the cost of a query Q scales with $|Q|$. Nearly linear-time oracle implementations exist for broad families of matroids, and this refined abstraction therefore captures the true cost of query evaluation while allowing for a more faithful comparison between general matroids and their natural special cases. Within this framework we study three fundamental algorithmic tasks: finding a basis of a matroid, approximating its rank, and approximating its partition size. We establish tight results, proving nearly matching upper and lower bounds that show the optimal query cost is (up to logarithmic factors) quadratic in the size of the matroid. On the algorithmic side, our upper bounds are realized by explicit procedures that construct the desired solution. On the complexity side, our lower bounds are unconditional and already hold even for weaker distinguishing formulations of the problems. Finally, for matroids with maximum circuit size at most c, we show that the quadratic barrier can be broken, providing an algorithm that calculates the maximum-weight basis with expected query cost $\mathcal{O}(n^{2-1/c} \log n)$.

AutoRAS: Learning Robust Agentic Systems with Primitive Representations

Yang Yue, Xuancheng Zhu, YuYang Ma, Guoshun Nan, Zihan Dou, JingRu Shan, Congyu Guo, Ji Zhang, Hua Wang, Jingfeng Zhang

The automated design of agentic systems offers a promising pathway for scaling large language models (LLMs) beyond single-agent reasoning. While prior work has advanced task performance through handcrafted or automatically generated multi-agent workflows, robustness is often treated as an afterthought, leaving systems vulnerable to external adversaries and internal failures. We propose AutoRAS, a framework for the Automated design of Robust Agentic Systems. AutoRAS formulates system design as generating a sequence of symbolic primitives that jointly encode structural connectivity and behavioral actions, and learns to optimize this sequence using execution-derived safety signals and flow-based sequence-level objectives. Extensive experiments show that AutoRAS achieves the best performance in both vanilla and adversarial settings, with the smallest performance degradation under attacks. Further analyses demonstrate strong transferability, stable optimization behavior, stability across primitive sets, and favorable cost trade-offs. Our code is available at [this link](https://github.com/guohezuy/AutoRAS).

ProbMoE: Differentiable Probabilistic Routing for Mixture-of-Experts

Heng Zhao, Zilei Shao, Guy Van den Broeck, Zhe Zeng

Mixture-of-Experts (MoE) models scale by activating only a small subset of experts per token.

However, training such models remains challenging because top-k routing is discrete and non-differentiable, requiring gradient estimators for expert selection whose design remains a central open problem. We introduce ProbMoE, a probabilis

tic routing framework that models expert selection as a distribution over cardinality-constrained expert subsets and formulates routing as probabilistic inference in this discrete subset space. We first propose ProbMoE Exact-k routing, which samples k-expert subsets in the forward pass, and the backward pass uses gradients through each expert's exact marginal probability as a tractable surrogate for the true gradient. ProbMoE naturally generalizes to a dynamic-k routing setting, where both training and inference constrain the routing cardinality to the same predefined range, allowing adaptive expert allocation per token. Across benchmarks and model backbones, ProbMoE Exact-k achieves strong performance compared to competitive baselines, with improved expert utilization and routing diversity; ProbMoE Dynamic-k achieves comparable performance with fewer activated experts. Code is available at: https://github.com/HengHugoZhao/ProbMoE.git

Frontier Models Can Take Actions at Low Probabilities

Alex Serrano, Wen Xing, David Lindner, Erik Jenner

Pre-deployment evaluations inspect only a limited sample of model actions. A misaligned model could evade oversight by randomizing the timing of policy-violating actions, executing them so rarely that none are observed during evaluation. But this requires taking actions at very low rates, while maintaining calibration. Are frontier models even capable of that? We prompt the GPT-5, Claude 4.5 and Qwen-3 families to take a target action at low probabilities (e.g. 0.01%), either given directly or requiring derivation, and evaluate their calibration (i.e. whether they perform the target action roughly 1 in 10,000 times when resampling). We find that frontier models are surprisingly good at this task. If there is a source of entropy in-context (such as a UUID), they maintain high calibration at rates as low as 1 in 100,000 actions. Without external entropy, some models can still reach rates lower than 1 in 10,000. When target rates are given, larger models achieve good calibration at lower rates. Yet, when models must derive the optimal target rate themselves, all models fail to achieve calibration without entropy or hint to generate it. Successful low-rate strategies exhibit explicit Chain-of-Thought (CoT) reasoning, so misaligned models attempting this approach could currently be caught by a CoT monitor. However, scaling trends suggest future evaluations may be unable to rely on models' lack of target rate calibration, especially if CoT is no longer legible.

Copyright-Bench: Agentic Evaluation of Copyright Law Compliance

Zheng Hui, Doni Bloomfield, Noam Kolt

Large language model (LLM) agents increasingly perform commercial tasks that involve retrieving external content such as images and, where appropriate, reproducing that content. LLM agents should comply with the law, including copyright law. Presently, however, we lack adequate frameworks to assess whether they do so in practice. To that end, we introduce **Copyright-Bench**, a benchmark designed to evaluate *LLM agents' compliance with* *copyright law*. Copyright-Bench is comprised of realistic commercial tasks---website development, merchandise design, and pitch deck production---that involve agents selecting between public-domain content (the use of which is *legal*) and copyrighted content (the use of which is *infringing* in this setting). The evaluation introduces prompt variations that simulate different user preferences, as well as time pressure. Comparing state-of-the-art LLM agents against a human baseline, we find that: (1) agents select copyrighted works despite the availability of public-domain alternatives; and (2) for open-weights models, violation rates increase in response to certain user preferences and simulated time pressure.

Sharpness-Aware Minimization Can Hallucinate Minimizers

Chanwoong Park, Uijeong Jang, Ernest K. Ryu, Insoon Yang

Sharpness-Aware Minimization (SAM) is widely used to seek flatter minima—often linked to better generalization. In its standard implementation, SAM updates the current iterate using the loss gradient evaluated at a point perturbed by distance ρ along the normalized gradient direction. We show that, for some choices of ρ, SAM can stall at points where this shifted (perturbed-point) gradie

nt vanishes despite a nonzero original gradient, and therefore, they are not sta tionary points of the original loss. We call these points hallucinated minimizer s, prove their existence under simple nonconvex landscape conditions (e.g., the presence of a local minimizer and a local maximizer), and establish sufficient c onditions for local convergence of the SAM iterates to them. We corroborate this failure mode in neural network training and observe that it aligns with SAM's p erformance degradation often seen at large ρ. Finally, as a practical safeg uard, we find that a short initial SGD warm-start before enabling SAM mitigates this failure mode and reduces sensitivity to the choice of ρ.

Beyond Literal Translation: Evaluating Cultural Effectiveness in Social Media UG C

Linjuan Wu, Ruiqi Zhang, Xinze Lyu, Ye Guo, Daoxin Zhang, Zhe Xu, Yao Hu, Yixin Cao, Yongliang Shen, Weiming Lu

Social media platforms enable large-scale cross-lingual communication, but trans lating user-generated content (UGC) remains challenging due to its informal styl e, cultural references, and interaction-based expressions. While recent LLMs hav e improved translation quality, existing benchmarks and metrics often fail to ca pture whether translations convey intended meaning and cultural resonance in rea l-world settings. In this work, we introduce **CULTURE-MT**, a benchmark for soc ial media translation that focuses on both **CUL**tural **T**ransmission and **U **GC-specific emotion **RE**sonance. CULTURE-MT consists of 1,002 UGC notes acro ss 14 domains, categorized into four types based on culture-loaded symbol and li nguistic style features. We also construct UGC-oriented training data to fine-tu ne Qwen3-8B and Qwen3-32B as baselines. We propose **cultural effectiveness** as a new evaluation criterion, focusing on expression accuracy and cultural adapta bility. Testing 15 models, including the baselines, we find that traditional met rics fail to capture cultural effectiveness. We also observe that cultural effec tiveness on base LLMs correlates with model size. Our work provides a comprehens ive evaluation system for UGC translation models and will offers an open evaluat ion platform to advance research in this area. We release the CULTURE-MT benchma rk and provide an online leaderboard where submitted translation results can be evaluated by our trained JUDGER.

Variational Speculative Decoding: Rethinking Draft Training from Token Likelihoo d to Sequence Acceptance

Xiandong Zou, Jianshu Li, Jing Huang, Pan Zhou

Speculative decoding accelerates inference for (M)LLMs, yet a training-decoding discrepancy persists: while existing methods optimize single greedy trajectories , decoding involves verifying and ranking multiple sampled draft paths. We propo se *Variational Speculative Decoding* (VSD), formulating draft training as varia tional inference over latent proposals (draft paths). VSD maximizes the marginal probability of target-model acceptance, yielding an ELBO that promotes high-qua lity latent proposals while minimizing divergence from the target distribution. To enhance quality and reduce variance, we incorporate a path-level utility and optimize via an Expectation-Maximization procedure. The E-step draws MCMC sample s from an oracle-filtered posterior, while the M-step maximizes weighted likelih ood using Adaptive Rejection Weighting (ARW) and Confidence-Aware Regularization (CAR). Theoretical analysis confirms that VSD increases expected acceptance len gth and speedup. Extensive experiments across LLMs and MLLMs show that VSD achie ves up to a 9.58\% speedup over EAGLE-3 and 8.80\% over ViSpec, significantly im proving decoding efficiency.

Towards Trustworthy Video Anomaly Understanding: A Class-Guided Chain-of-Evaluat ion Metric and An Anomaly-focused Meta-Benchmark

Jiaxu Leng, Zhoujie Huang, Mingpi Tan, Zhanjie Wu, Xinbo Gao

The trustworthiness of evaluation is critical to reliable model comparison and d eployment in Video Anomaly Understanding (VAU). However, existing metrics are se nsitive to expression styles and normal content, and this field lacks a diagnost ic benchmark to validate metric validity and robustness. To bridge this gap, we

propose: (1) a Class-Guided Chain-of-Evaluation (CG-CoE) metric, which structures assessment by extracting anomalous events and matching them under a class-specific semantic tolerance boundary, thereby decoupling anomaly semantics from descriptive style; and (2) an anomaly-focused meta-evaluation benchmark with two subsets: Anomalous Event-level Annotations (AEA) for measuring the validity of reflecting VAU models' anomaly understanding ability and Controlled Variant Pairs (CVP) with fixed anomalies for quantifying robustness to stylistic perturbations.
  Extensive experiments demonstrate that CG-CoE achieves SOTA validity and robustness.

MergeMix: Optimizing Mid-Training Data Mixtures via Learnable Model Merging
jiapeng wang, Changxin Tian, Kunlong Chen, Ziqi Liu, Jiaxin Mao, Xin Zhao, Zhiqiang Zhang, JUN ZHOU
Optimizing data mixtures is is essential for unlocking the full potential of of large language models (LLMs), yet identifying the optimal composition remains computationally prohibitive due to reliance on heuristic trials or expensive proxy training. To address this, we introduce MergeMix, a novel appraoch that efficiently determines optimal data mixing ratios by repurposing model merging weights as a high-fidelity, low-cost performance proxy. By training domain-specific experts on minimal tokens and optimizing their merging weights against downstream benchmarks, MergeMix effectively optimizes the performance of data mixtures without incurring the cost of full-scale training. Extensive experiments on models with 8B and 16B parameters validate that MergeMix achieves performance comparable to or surpassing exhaustive manual tuning while drastically reducing search costs. Furthermore, MergeMix exhibits high rank consistency (Spearman $\rho > 0.9$) and strong cross-scale transferability, offering a scalable, automated solution for data mixture optimization.

Elign: Equivariant Diffusion Model Alignment from Foundational Machine Learned Force Fields
Yunyang Li, Lin Huang, Luojia Xia, Wenhe Zhang, Mark Gerstein
Generative models for 3D molecular conformations must respect Euclidean symmetries and concentrate probability mass on thermodynamically favorable, mechanically stable structures. However, E(3)-equivariant diffusion models often reproduce biases from semi-empirical training data rather than capturing the equilibrium distribution of a high-fidelity Hamiltonian. While physics-based guidance can correct this, it faces two computational bottlenecks: expensive quantum-chemical evaluations (e.g., DFT) and the need to repeat such queries at every sampling step. We present Elign, a post-training framework that amortizes both costs. First, we replace expensive DFT evaluations with a faster, pretrained foundational machine-learning force field (MLFF) that estimates molecular energies and forces. Second, we eliminate repeated run-time queries by shifting physical steering to the post-training phase. To achieve the second amortization, we formulate reverse diffusion as a reinforcement learning problem and propose to use Group Relative Policy Optimization (GRPO) to fine-tune the denoising policy. Our objective combines a potential-based energy reward and a force-based stability reward, which are optimized in a disentangled fashion. Experiments show that Elign generates conformations with lower gold-standard DFT energies and forces, while improving stability. Crucially, inference remains as fast as unguided sampling, since no energy evaluations are required during generation.

SVD as a Fast Interpretability Method for Transformers
Min Xue, Artur Andrzejak
Mechanistic interpretability of Transformer models commonly relies on training auxiliary proxy models, such as Sparse Autoencoders or Cross-Layer Transcoders. While effective, these post-hoc approaches introduce approximation bias and incur substantial computational overhead. We propose an alternative, training-free interpretability framework that directly exploits the Singular Value Decomposition (SVD) of weight matrices in Transformer MLP sublayers. By operating natively on model parameters, our method improves scalability while preserving fidelity to

the original weights. We show that the projection matrices of MLP sublayers admit a natural decomposition into orthogonal, interpretable rank-1 subspaces, which we term **Detector-Effector Units** (DEUs). Within each unit, a singular vector functions as a detector of input patterns and modulates a coupled effector vector that encodes output semantics. Building on this structure, we introduce **Subspace Contribution Analysis** (SCA), a diagnostic method that quantifies the direct causal contribution of individual native subspaces to model predictions. Experiments across the GPT-2 family demonstrate that our framework, **Native Network Anatomy** (NaNA), identifies dominant functional pathways with orders-of-magnitude efficiency gains over training-based interpretability baselines, while maintaining weight fidelity. Our results suggest that SVD-based analyses provide a scalable and faithful alternative to learned proxy approaches for mechanistic interpretability.

ChartE^{3}: A Comprehensive Benchmark for End-to-End Chart Editing

Shuo Li, Jiajun Sun, Zhekai Wang, Xiaoran Fan, Hui Li, Dingwen Yang, Zhiheng Xi, Yijun Wang, Zifei Shan, Tao Gui, Qi Zhang, Xuanjing Huang

Charts are a fundamental visualization format for structured data analysis. Enabling end-to-end chart editing according to user intent is of great practical value, yet remains challenging due to the need for both fine-grained control and global structural consistency. Most existing approaches adopt pipeline-based designs, where natural language or code serves as an intermediate representation, limiting their ability to faithfully execute complex edits.

We introduce ChartE^{3}, an **E**nd-to-**E**nd Chart **E**diting benchmark that directly evaluates models without relying on intermediate natural language programs or code-level supervision. ChartE^{3} focuses on two complementary editing dimensions: local editing, which involves fine-grained appearance changes such as font or color adjustments, and global editing, which requires holistic, data-centric transformations including data filtering and trend line addition.

ChartE^{3} contains over 1,200 high-quality samples constructed via an well-designed data pipeline with human curation. Each sample is provided as a triplet of a chart image, its underlying code, and a multimodal editing instruction, enabling evaluation from both visual and structural perspectives. Extensive benchmarking of state-of-the-art multimodal large language models reveals substantial performance gaps, particularly on global editing tasks, highlighting critical limitations in current end-to-end chart editing capabilities.

FaPS: A General and Fast Training Method for Diffusion Models

Xianglu Wang, Bangxian Han, Hu Ding

Diffusion models have achieved state-of-the-art performance in image generation tasks. However, training powerful diffusion models remains time-consuming, which limits their practical deployment. In this paper, we revisit the learning dynamics of diffusion models through the lens of *spectral bias*, a phenomenon in which deep neural networks prioritize learning low-frequency modes. Through an empirical analysis of diffusion training, we observe that diffusion models exhibit a **dual** spectral bias. First, over training iterations, they fit low-frequency components earlier than high-frequency details. Second, along the diffusion timesteps, early denoising steps mainly reconstruct coarse low-frequency content, while high-frequency details emerge in later steps. Motivated by this observation, we propose Frequency-aware Patch Selection **(FaPS)**, a general and fast training method for diffusion models that can
be applied to both UNet and DiT backbones.

Specifically, FaPS introduces a *frequency-aware gating* that adaptively selects image patches based on their frequency information and focuses computation only on the selected patches. Since the selection decisions are discrete and thus non-differentiable, we model the gating as a stochastic policy network and optimize it end-to-end using a policy gradient method.

Our experiments demonstrate that FaPS achieves up to $\mathbf{3}\times$ faster training while maintaining comparable or superior generation quality, and improves the performance of diffusion models in limited-data settings.

DropoutTS: Sample-Adaptive Dropout for Robust Time Series Forecasting
Siru Zhong, Yiqiu Liu, Zhiqing Cui, Zezhi Shao, Fei Wang, Qingsong Wen, Yuxuan L iang
Deep time series models are vulnerable to noisy data ubiquitous in real-world ap plications. Existing robustness strategies either prune data or rely on costly p rior quantification, failing to balance effectiveness and efficiency. In this pa per, we introduce DropoutIS, a model-agnostic plug■n that shifts the paradigm fr om what to learn to how much to learn. DropoutTS employs a Sample-Adaptive Dropo ut mechanism: leveraging spectral sparsity to efficiently quantify instance-leve l noise via reconstruction residuals, it dynamically calibrates model learning c apacity by mapping noise to adaptive dropout rates, selectively suppressing spur ious fluctuations while preserving fine-grained fidelity. Extensive experiments across diverse noise regimes and open benchmarks show DropoutTS consistently boo sts superior backbones' performance, delivering advanced robustness with negligi ble parameter overhead and no architectural modifications. Code is available at https://github.com/CityMind-Lab/DropoutTS.

PHALAR: Phasors for Learned Musical Audio Representations
Davide Marincione, Michele Mancusi, Giorgio Strano, Luca Cerovaz, Donato Crisost omi, Roberto Ribuoli, Emanuele Rodolà
Stem retrieval, the task of matching missing stems to a given audio submix, is a key challenge currently limited by models that discard temporal information. We introduce PHALAR, a contrastive framework achieving a relative accuracy increas e of up to ≈ 70% over the state-of-the-art while requiring <50% of the parameters and a 7$\times$ training speedup. By utilizing a Learned Spectral Po oling layer and a complex-valued head, PHALAR enforces pitch-invariant and phase -equivariant biases. PHALAR establishes new retrieval state-of-the-art across Mo isesDB, Slakh, and ChocoChorales, correlating significantly higher with human co herence judgment than semantic baselines. Finally, zero-shot beat tracking and l inear chord probing confirm that PHALAR captures robust musical structures beyon d the retrieval task.

UOTIP: Unbalanced Optimal Transport Map for Unpaired Inverse Problems
Donggyu Lee, Taekyung Lee, Jaewoong Choi
We investigate unpaired image inverse problems, a challenging setting where only independent, non-paired sets of noisy measurements and clean target signals are available for training.
We propose a novel inverse problem solver based on Unbalanced Optimal Transport, called ***Unbalanced Optimal Transport Map for Inverse Problems (UOTIP)***. Our method formulates the reconstruction task—predicting clean target signals from noisy measurements—as learning a UOT Map from noisy measurement distribution to clean signal distribution by incorporating a likelihood-based cost function. By relaxing the exact marginal constraint, the UOT framework provides key advantage s to our model: robustness to multi-level observation noise, adaptability to cla ss imbalance between noisy and clean datasets, and generalizability to diverse n oise-type scenarios.
Furthermore, we theoretically demonstrate that incorporating a quadratic cost te rm ensures the existence and uniqueness of the transport map by satisfying the t wist condition, even for ill-posed inverse problems.
Our experiments demonstrate that UOTIP achieves state-of-the-art performance on unpaired image inverse problem benchmarks, across linear and nonlinear inverse p roblems.
****
AdaSplash-2: Faster Differentiable Sparse Attention
Nuno Gonçalves, Hugo Pitorro, Vlad Niculae, Edoardo Ponti, Lei Li, Andre Martins , Marcos Vinicius Treviso
Sparse attention has been proposed as a way to alleviate the quadratic cost of t ransformers, a central bottleneck in long-context training.
A promising line of work is α-entmax attention, a differentiable sparse a

lternative to softmax that enables input-dependent sparsity yet has lagged behin
d softmax due to the computational overhead necessary to compute the normalizer
τ.
In this paper, we introduce AdaSplash-2, which addresses this limitation through
 a novel histogram-based initialization that reduces the number of iterations ne
eded to compute τ to typically 1-2. The key idea is to compute a coarse his
togram of attention scores on the fly and store it in on-chip SRAM, yielding a m
ore accurate initialization that enables fast forward and backward computation.
Combined with a sparsity-aware GPU implementation that skips zero blocks with lo
w overhead, AdaSplash-2 matches or improves per-step training time relative to F
lashAttention-2 when block sparsity is moderate-to-high (e.g., $>$60\%), which o
ften occurs at long-context lengths.
On downstream tasks, models trained with our efficient α-entmax attention
 match softmax baselines at short-context lengths and achieve substantial gains
in long-context settings.

Reading the Cell, Designing the Cure: Perturbation-Conditioned Molecular Diffusi
on for Function-Oriented Drug Design
ZIYU XU, zijian zhang, Liang Wang, Zhiyuan Liu, Qiang Liu, Shu Wu, Liang Wang
When reliable target structures are unavailable at scale or phenotypes arise fro
m dysregulated pathways, transcriptomic perturbations provide a system-level fun
ctional readout for drug action. In this work, we formalize Transcriptome-based
Drug Design (TBDD) as a generative inverse problem: designing drug molecules con
ditioned on desired transcriptomic state transitions. We analyze the inherently
ill-posed nature of this task, which is further complicated by the profound doma
in gap between biology and chemistry and by the sparsity of transcriptomic signa
ls. To address these challenges, we propose CURE (A CellUlar Response Engine), a
 multi-resolution transcriptome-guided diffusion framework. CURE features a spec
ialized Transcriptome Perturbation Functional Feature Extractor (TFE) that (1) d
istills function-oriented perturbation embeddings from pre/post states, (2) alig
ns these signatures to dual chemical views to bridge the cross-modal gap, and (3
) performs heterogeneity-aware aggregation to extract robust state-specific sign
als from noisy transcriptomic data. Extensive evaluations on both standard bench
marks and rigorous out-of-distribution protocols demonstrate that CURE consisten
tly outperforms strong baselines in structural quality and functional consistenc
y. Furthermore, we validate its practical utility via a zero-shot gene-inhibitor
 design task, highlighting the potential of phenotype-driven generative discover
y.
****

An Algebraic View of the Expressivity of Recurrent Language Models
Franz Nowak, Ryan Cotterell, Reda Boumasmoud
What formal languages can a recurrent neural language model recognize? Formal re
sults in the literature conflict: some authors report Turing-completeness, while
 others show equivalence to regular languages.
The reason for this discrepancy is that the underlying arithmetic model differs.

The paper develops a unified algebraic account of the expressivity of recurrent
neural networks, starting with a formal account of various arithmetic models.
This account reduces expressivity to an algebraic question, e.g., whether a netw
ork's syntactic monoid divides a certain wreath product.
As a case study, the paper revisits diagonal state-space models: the same archit
ecture cannot implement an even-modulus counter once floating-point recurrences
are enforced, yet realizes every even-modulus counter under unsigned-integer qua
ntization.
****

Rex: A Family of Reversible Exponential (Stochastic) Runge-Kutta Solvers
Zander W. Blasingame, Chen Liu
Deep generative models based on neural differential equations have become state-
of-the-art for many generation tasks.
These models rely on ODE/SDE solvers that integrate from a prior distribution to

the data distribution; in many applications it is also highly desirable to integrate in the inverse direction.
Standard solvers, however, accumulate discretization errors that prohibit *exact inversion*, an inaccuracy that is unacceptable in precision-critical applications.
Existing inversion methods suffer from poor stability and low order of convergence, and are strictly limited to the ODE setting.
In this work, we propose *Rex*, a family of reversible exponential (stochastic) Runge-Kutta solvers obtained by applying Lawson methods to convert any explicit (stochastic) Runge-Kutta scheme into an algebraically reversible one for both diffusion ODEs *and* SDEs.
Beyond a rigorous theoretical analysis---establishing arbitrary-order convergence and a non-zero region of linear stability---we empirically demonstrate that *Rex* achieves near-machine-precision reconstruction and improves Boltzmann sampling with flow models as well as image generation and editing with diffusion models.
****

Transport and Merge: Cross-Architecture Merging for Large Language Models
Chenhang Cui, Binyun Yang, Fei Shen, Yuxin Chen, Jingnan Zheng, Xiang Wang, An Zhang, Tat-Seng Chua
Large language models (LLMs) achieve strong capabilities by scaling model capacity and training data, yet many real-world deployments rely on smaller models trained or adapted from low-resource data. This gap motivates the need for mechanisms to transfer knowledge from large, high-resource models to smaller, low-resource targets.
While model merging provides an effective transfer mechanism, most existing approaches assume architecture-compatible models and therefore cannot directly transfer knowledge from large high-resource LLMs to heterogeneous low-resource targets.
